AN ENTIRE
Body of Philosophy,
According to the
PRINCIPLES
James Of the Famous *Flower*,
RENATE DES CARTE'S,
In Three Books:

- I. The INSTITUTION, in X. Parts; 1. *Logick*. 2. *Natural Theology*. 3. *Dæmonology*, or of *Created Spirits*. 4. *General Physicks*, or *Natural Philosophy*, generally considered. 5. *Special Natural Philosophy*, of the *World and Heaven*. 6. The Four Great Bodies, *Earth, Water, Air and Fire*, and what have their rise from them; where, of *Metals* and *Meteors*. 7. Of *Living Things* in general, and in particular of *Plants and Animals*. 8. *Man*, in respect to his *Body*. 9. *Man*, as to his *Mind or Soul*. And, 10. *Ethicks*, or *Moral Philosophy*, treating of *Man's* right Ordering his Life.
- II. The HISTORY of NATURE, which Illustrates the *Institution*, and consists of great Variety of *Experiments* relating thereto, and explained by the same *Principles*, in IX. Parts, 1. Of *Bodies*. 2. Of *Qualities*. 3. Of the *Earth and Heaven*. 4. Of the *Earth, Water, Fire and Air*. 5. Of *Things* dug out of the *Earth*. 6. Of *Meteors*. 7. Of *Plants*. 8. Of *Animals*. And, 9. Of *Man*.
- III. A Dissertation of the Want of SENSE and KNOWLEDGE in BRUTE ANIMALS, in II. Parts, giving a *Mechanical Account* of their Operations.

Written Originally in Latin by the Learned
ANTHONY LE GRAND.

Now carefully Translated from the last Corrections, Alterations, and large Additions of the Author, never yet Published.

The Whole WORK Illustrated with almost an Hundred
SCULPTURES
Dispersed to such places as best admit thereof: All designed, Drawn and Engraven *Historically* by good Artists. Besides the FIGURES or SCHEMES for the Explanation of the *Philosophical Parts* that require the same.
Endeavoured to be so done, that it may be of Use and Delight to the Ingenious of both Sexes.

By RICHARD BLOME

L O N D O N:

Printed by *Samuel Roycroft*, and Sold by the Undertaker *Richard Blome*, dwelling in *New Weld-street*, at the *Green Pales*, near *Clare-Market*: And at these Booksellers following; *Mr. Horn* and *Mr. Southby* by the *Royal Exchange*; *Mr. Chiswell*, *Mr. Clavell* and *Mr. Brome*, in *S. Pauls Church-yard*; *Mr. Tonson*, in *Fleetstreet*; *Mr. Saunders*, in the *New Exchange*; *Mr. Gilliflower*, in *Westminster-Hall*; and *Mr. Richards*, at the *Bible*, the Corner of *Essex-Street*, against *S. Clements Church*. MDCXCIV.

En D'prie Books

T O T H E

Right Honourable, and Truly Noble,

H E N R Y

Lord Viscount *Sydney* of *Shepey*,

Baron *Milton*, Lord Lieutenant of *Kent*, Constable of *Dover Castle*, Lord Warden of the *Cinque Ports*, Master General of Their Majesties *Ordnance*, Colonel of Their Majesties First Regiment of Foot Guards, one of the Gentlemen of His Majesties Bedchamber, and one of the Lords of Their Majesties Most Honourable Privy Council, &c.

My Lord,

I Am not unsensible that some part of the World, when they shall see your Lordships Name affixt to this Book, will be apt to say, That my inducements for laying it at your Honours Feet, are those generally made use of by Authors; to wit, the necessity of an illustrious Patronage to defend the Work against the assaults of Envy and Ignorance: But I must beg leave to assure your Lordship and the World, that the true Reason for this my Dedication, ariseth from a well-grounded Belief, and the general concurrence of the Learned Part of this Nation, that your Honour is the properest Person to patronise a Work of this Nature, having by all the Actions of your Admired Life fully convinced the World, that you only are the absolute Master of the whole Body of PHILOSOPHY; and I my self have ever held it as a reasonable Position, That the Works of the Learned, like the Actions of the Noble, ought only to be judged by their Peers; nor can I think your Lordship, or any Learned Person will say, that a virtuous desire of Knowledge (and such I humbly conceive is Philosophy) needs or wants a Protection from any, since 'tis an experienced Truth, That Virtue carries her own Safeguard, as well as her own Reward.

But as to the Subject Matter of this Book, and the method of handling it, I shall not say any thing, but refer your Lordship to the Book it self, of which your Honour is so great a Judge; having in my memory, the admonition of Apelles to Alexander the Great, speaking improperly of the Noble Art of Painting; In things you understand not, says that Great Artist, be alwaies silent, lest by speaking, you betray a want

The Dedication.

of Judgment. But as for the Designing and Engraving the SCULPTURES which Imbellishes this Work, things more properly mine, than any other part of the Book, and in which through Practice and Experience I may be allowed to have some knowledge; I must beg leave to assure your Lordship, that they are, if not accurately, at least elaborately done; and had I not been therein concern'd, might have ventured to have said, they are the best ever made publick in this Nature and Nation. And if they be so happy as to contribute in the least to your Honours Satisfaction, or Entertainment, I shall thereby be abundantly rewarded for all my Care, Charge and Trouble; for the very White at which I aimed, both in publishing this Book, and writing this Epistle, was to have it in my power to declare to your Lordship, that the ultimate of my Ambition is to serve you whilst I Live, and when Dead, to be recommended to Posterity under this desirable Character, That I had the happiness to be known to your Honour, who is allowed by all the Judicious, to be the Glory of the Age you live in, and to excel all that have gone before you, and to stand a Great, Noble, and hardly to be pattern'd Example to those that shall succeed. And of You, most Noble Sir, 'tis with more Truth than Complement said, that HENRY Lord SYDNEY doth abundantly surpass both in Wisdom and Heroick Performances, the so much famed Sir PHILIP SYDNEY (whom, the Age he lived in, thought worthy to be a King) and that in times to come they will mention his Alliance to you, to aggrandize his Character. Nor are these, my Lord, half the Hecatombs of Praise offered up to your great Merit, by the grateful and understanding part of Mankind; nor one third of what I might justly say: But such is your Lordships great Modesty, to be equalled by nothing but your Courage, that you always decline hearing a recital of your Illustrious Actions, tho' you never omit any opportunity of performing them: And therefore I shall only beg leave to tell your Honour, with all due Deference to your Exalted Station; that there is no part of the World which You have graced with Your Presence, and obliged with Your Goodness, is, or can be more truly sensible of what they owe You, or more willing entirely to sacrifice their All to your Lordships Service, than the Publisher of this Work; who is, may it please your Honour, with the most profound Respect imaginable,

My Lord,

Your Honours

most Obligated, and most Humble Servant,

Richard Blome.

THE

THE EPISTLE TO THE READER.

BY my indefatigable *Labour* for these twenty Years, I have employed my time, with no small *Expences* in the *Printing* of several *Volumes*, not only *Useful*, but *Honourable* to this *Nation*, which have met with a kind *Reception* from the *Nobility* and *Gentry*, some of which I shall here give the *Reader* a short account of, as having a small quantity of each remaining, which the *Curious* may be accommodated with. And this their *Encouragement* has emboldned me to undertake this Great Work in *English*, which of all *Subjects*, is the most wanting; and the rather, because appearing in our *Native Tongue*, 'tis thereby more useful for the *Publick Good*, and of more universal *Benefit*. For it seems a kind of *Illnatur'd Retrenchment* upon the common *Freedom* of *Mankind* to lock up all *Ingenious Arts* and *Sciences* from them, unless they are *Masters* of a *Greek* or *Latin Key* to open 'em. The *Travel* into *PHILOSOPHY* and true *Wisdom*, like the *Commerce* into the *Rich Indies*, should be declared *Free*, and of equal *Right* to all the *Subjects* of *England*, without incurring the *Premunire* of *Interlopers*.

Tongues and *Languages*, I confess are a fine and sumptuous *Portico*; but then they are no more than a *Portico*. The *Sciences* to which they introduce, are the *Main Mass* and *Body* of true *Learning*; and 'tis somewhat of the hardest, that so fair a *Pile* should have that only *Gate* to enter at: Besides, not to instance how many, otherwise very *ingenious Men*, are hereby debarr'd the *Study* of *Wisdom* and *Virtue*, whilst couch'd only in a *Language*, which possibly their *Education*, or want of *Leisure* has not made them *Masters* of: Here's a perfect *Turkish* piece of *Cruelty*; for we thus make *Learning* an absolute *Mahometan Mosque*, whilst the whole *Fair Sex* are at once excluded from any part of their *Devotion* in it. And let me tell you, the most complaisant *French Authors* generally *Print* their *Philosophical Books* in their own *Language*, by which the *French Ladies*, to the *Glory* of their *Sex*, have arrived to a great perfection of *Knowledge*; in which extraordinary *Accomplishments*, being able to discourse of the *Heavens*, the *Motion* of the *Planets*, and the *Nature* and *Causes* of *Mundane Things*, &c. beside the *Improvement* of *Virtue*, they have elevated their *Conversation* above the *Common Rate* of *Feminine Eloquence*, such as their descant upon *Commodities*, *New Fashions*, or the little *Vanities*, and have added no little *Charm* and *Grace* to many *Protest Virtuosos*. And truly tho' we have at present set up our *Standard* against *France*, yet I could wish we might still continue one piece of *Friendship*, viz. our old *Custom* of following the *Mode* of *France*, in bringing that one *French Fashion* up, of making our *Learning* speak *English* to instruct both ours, and the *Fair Sex*.

And altho' this *Volume* of *PHILOSOPHY* has been so well received in *Latin* by the *Sale* of several *Impressions*, yet for the making it more exact and perfect, I contracted with the *Author* *Mr. Le Grand* to make *Additions* thereunto; so that by his large *Additions* and great *Alterations* throughout, it may be boldly said to be a *New Book*, and the best yet extant in any *Language*.

My

The Epistle.

My next business was to employ an able *Translator* and *Supervisor*, which with the care of the said Mr. *Le Grand*, every thing throughout is rendred so facile, and adapted to the *English Dress*, as to be of *Use* and *Delight* to all *Persons*. I have also Engraven the *SCHEMES* or *FIGURES* that were formerly in *Wood*, now on *Copper*: And for the adornment of the said *WORK*, have illustrated it with above 90 *SCULPTURES*, *Historically* and *Poetically Designed*, and Engraven by good *Artists*, relating to the several *Subjects* that best admit thereof: And have added an *Explanatory INDEX* or *TABLE* of the several *SCULPTURES*, that the *Reader* may the better know the meaning thereof.

The *SCHEMES* or *FIGURES* are Engraven on three *Copper Plates*, two for those in the *Institution*, and one for those in the *History of Nature*, all numbred 1, 2, 3, 4, and so on as in the *Plates*, with reference to the *Book* by the *Folio*, and the said number in the *Margent*; which said *Plates* of *Schemes* are to be placed at the beginning of the *Book* next the *Preface* of Mr. *Le Grand*, which gives you an account of the *Work*, and the *Arms* of the *Benefactors* to follow the *Schemes*.

Richard Blome.

An Account of some Volumes which the Curious may be accommodated with by me.

The *Gentleman's Recreation*, in Two Parts, in large Folio. The first, of the *Liberal* and *Mathematical Sciences*; which in a brief and clear Method treats of the *Doctrin* and *General Parts* of each *Art*, with *Elliptical Tables* engraven on *Copper Plates*, for the better comprehending the same. The Second Part at large treats of *Horsemanship*, *Hawking*, *Hunting*, *Fowling*, *Fishing* and *Agriculture*; all being Collected from the most Authentick *Authors*, and the many gross Errors therein Corrected, with great *Enlargements* made by those well Experienced therein. And for the better Explanation thereof great variety of useful *Sculptures*, as *Nets*, *Engins*, *Traps*, &c. are added, for the taking of *Beasts*, *Fowl* and *Fish*, not published by any: Nothing material being omitted for the rendring them Compleat. The whole Illustrated with about 86 Ornamental *Copper Plates*; in Folio.

The *History* of the *Old* and *New Testament*, treating of the most remarkable Transactions therein, with good and useful *Morals*, for the better government of our Actions in all Conditions. To which is added, the *Travels*, *Voyages* and *Lives* of the *Apostles*; with a large *Historical Chronology* of such Matters of Note that are related in the *Bible*: Collected and Translated by good Hands, from Authentick *Authors*. The whole Illustrated with about 240 *Sculptures*, of the most remarkable Passages, performed by good *Artists*, far surpassing any Collection hitherto done, to the end it may be the more acceptable to the Curious. This *Work* is Printed in Two Volumes in large Folio, of a fair Print, and chiefly designed for the Curious.

The said *Work* is likewise Printed in large *Octavo*, with all the *Sculptures*, as designed for a more general Sale, for *Youth*, to Instruēt them in the *Historical* parts of the *Bible*: *Sculptures* being lively *Emblems*, to imprint the same in their *Memories*.

A useful Volume of *Cosmography* and *Geography*, in Two Parts, in Folio. The First, of the Arts of *Cosmography* and *Geography*, being a Translation of the much Esteemed *VARENIUS*. The Second Part is a *Geographical Description* of the *World*, from the *Works* of the Famous Monsieur *SANSON*; with about a 100 *Geographical Tables* of the *Kingdoms* and *Isles* in the *World*, with their Chief Places, drawn from the Maps of the several *Kingdoms*, which illustrates this *Work*. And to this Impression are added the *County Maps* of *England*, drawn from those of *Speed's* in a smaller Scale.

THE

T H E C O N T E N T S O F E A C H C H A P T E R In each Part of the INSTITUTION of P H I L O S O P H Y.

The first Part concerning LOGIC, in 23 Chapters.	Of the General Method of Knowing,	ibid.
Introduction of the Nature and Constitution of Logick, Folio 1	Concerning special Method; and first of that which is called Analitical,	44
Of the true use of Logick, shewing that Logick is useful and necessary to the conduct of a Rational Life,	Of the Method of Composing,	46
The first part of Logick; of the clear and distinct perception of the Mind.	Rules of Definitions. Rules of Axioms,	47
What the hindrances of Science are, and how to be removed,	Most General Axioms. Special Logical Axioms: from the Genus: from the Species: from the Forms or Differences: from the Property: from the Definition: from Division.	48, 49, 50
Some Rules for the attainment of Truth,	From the Cause: from the Effect: from the Subjunct, and Adjunct: from the Whole: from the Parts: from Like and Unlike: from Contraries: from Privative Opposites: from Contradictories: from Parity or Equality: from the Greater: from the Lesser: from Divine Authority: from Human Authority. Rules of Demonstration,	51
Concerning the various Modes of Perception, viz. pure Intellection, Imagination and Sense,	Of General Method,	52
Of the 5 Universals, or Predicables,	The Second Part, viz. Natural Theology.	
Universals singly examined, as to their Nature, Properties and Use,	in 16 Chapters.	
Of Substance, and its Affections and Modes,	An Introductory Discourse of the Definition of Natural Theology, and its certainty,	53
Of the Common Attributes of Substance,	What God is, and how he may be reached by us,	54
How the name of Substance agrees to God, and the Creatures,	By the Inborn Idea that is in us, we know that God exists,	56
The Genealogy of Things and Modes,	That it belongs to the Nature of God to exist,	58
Of the Whole and Parts, Causes and Effects, Subject and Adjunct,	The Contemplation of the World proves God's existence,	59
Concerning the distinctions, whence the nature and difference of Idea's is deduced,	Concerning Fate and Will, or the Divine Decree,	62
Of the Imposition, Signification, Definition and use of Names,	How God is said to be the Cause of Propositions of Eternal Truth,	63
The Second Part of Logick.	Concerning the Divine Attributes, and first of the Unity of God,	64
Concerning the right judgment of the Mind, or Proposition,	That God is Eternal, or without beginning or end,	65
Of Judgment, absolute and compared,	That God is Infinite, and how we are to understand, that he is circumscribed to no place,	66
What a Proposition is, and how manifold, with the several Rules,	That God is the most Simple Being,	67
Concerning the Truth and Falshood of Propositions, with the Rules,	God is true, and as he can't be deceiv'd so he cannot deceive,	68
Of Division and Definition, with the Rules,	That God is the most highly Intelligent, or Omniscient,	69
The Third Part of Logick.	That God is Good, and doth Good,	70
Concerning the Minds Ratiocination, Syllogism,	Of the Omnipotence of God,	71
Of Reasoning, or Argumentation,	That God is the Creator of all things,	73
Of simple Syllogisms, and those either Complex, or Incomplex,	Concerning God's Government of the World, and Providence,	74
Of Conjoin'd or Compound Syllogisms,	The Third Part, viz. of Dæmonology, or of Intelligences and Created Spirits, in 11 Chapters.	
Of Imperfect Arguments,	A Prefatory Discourse, of the Division of Created Things; the Definition of Pneumaticks, or the

		A <i> Dissertation of want of Sense and Knowledge in Brute Animals,</i>	225
		<i>The Contents of which Discourse appears accord- ing to the several Articles printed in the Mar- gent, to which the Reader is referred.</i>	

An Explanation of the Sculptures in this Work.

First in the INSTITUTION of PHILOSOPHY

TH E Title, represented by the Figure of *Fidelity*, sitting on a Chair ascended by three Steps, which Steps are Emblems of those three Parts of *Philosophy*, over which we must pass, before we can arrive at the perfection of *Truth*; her *Eagle* denotes her quick-sightedness, by which she is able to read the Book, held at that distance, *clear & distinct* (plainly and distinctly) as is therein written, whilst the *Sun* that seems to enlighten the Book, is an Emblem of that assistance *Heaven* freely affords us in our virtuous pursuit of *Learning* and *Knowledge*: The Figure with its Foot on the first Step of the ascent, as likewise that with the *Globe*, and the other behind are Emblems of some *Proficients* in *Philosophy*, their particular progression in that noble Study being denoted by *precedency* of order.

In the *Preface*, the *Sculpture* represents the several *Pourtraitures* of those *Philosophers*, cited by the Author in his *prefatory Discourse*; those standing on the fore-ground, are *Descartes*, *Gassendus*, *Epicurus* and *Zeno*, the fittest to have the first place in this *Sculpture*, since by their *Works* they contributed most to the building this *Body of Philosophy*; which Emblem may likewise teach us not to be forgetful of those from whom we have received *Benefits*.

LOGICK, Part 1. Chap. 1. fol. 1. Represented by a *Woman* sitting in a Chair, holding in her Right Hand a two pointed *Sword*, and in her Left a *Serpent*, who twists about her Arm; on her Head, a *Helmet* surmounted by an *Eagle*; beneath her Feet are *Books*, *Swords* and *Garlands*, with *Boys*, having *Keys* and *Locks* in motion; at a distance two *Philosophers* discoursing: Her *Swords* are her most proper Emblems, *Logick* being *pugnatio Verborum* (a Word-fight); her *Snakes* denote her subtilty, her *Helmet* her strength, and her *Eagle* her discerning faculty; the *Locks* and *Keys* denote her power to lay open or conceal; the *Garlands* on the *Pedestals* of the *Pillars*, are the *Trophies* of her *Victories* gained over other parts of *Learning*, which *Victory* is represented by her having *Books*, *Swords* and *Garlands* laid at her Feet; the *Sword* occupying her Right Hand, and the *Snakes* her Left, denotes *Powers*, being nobler than *cunning*: The building in prospect, is the *School of Learning* dedicated to the Goddess *Minerva*.

LOGICK with *Truth* and *Falshood*, Part 1. Chap. 2. fol. 3. The Figure which seems just risen from her Chair is *Logick*, as appears by her usual Emblems, (treated of before) the Figure whom she seems to court, is *Truth*, represented with a *Glory* round her Head, having a loose *Garment* cast about her; the *Glory* denotes her Excellence, and her regardless *Robe* shews that *Truth* needs no Ornament, nor ought to be covered, tho' with the

most pleasing and becoming pretences: The Figure next her, represents *Falshood*, being a *Syren* with a *Mask* and *Mirror*, the proper Emblems of that Vice, it being reported of that Creature, that she destroys with her Voice all that give ear to her; her *Mirror* denotes the double dealing of *Falseness*, and her *Mask* the disguises she is forced to make use of (for as it is said of *Virtue*, that could Men see her Naked, they would be most passionately enamoured of her,) so on the contrary, could they see *Falsity* undrest of her *Masks* and *Disguises*, they would flee from her, as the ugliest and most dangerous Monster. The Building behind, represents the Palace of *Logick*, being the *School of Learning*.

LOGICK discovering *Falshood*, Part 1. Chap. 2. Rule 1. fol. 5. The representation of *Logick* as before, viewing intently the *Syren*, who has covered her Face with a *Mask*, under which appearance she endeavours to pass for *Truth*; but her lower parts being her badge of distinction, are uncovered by a little Boy, and so she is detected; which shews that the best maskt *Falshood* is discoverable by *Truth* and *Innocence*, tho' in its Childhood.

LOGICK embracing *Truth*, Part 1. Chap. 2. Rule 4. fol. 8. The *Sculpture* represents a *Garden*, in which the Figure of *Logick* appears together with *Truth*, both emblemis'd as before; the seeming Imbraces of *Logick* given to *Truth*, denote the acceptableness of it to *Learning*; they being placed in a *Garden*, is to shew the Pleasures and Sweets that attend them both.

JUDGMENT, Part 1. Chap. 11. fol. 26. Represented by an elderly *Man* sitting on a *Rainbow* in the *Clouds*, having *Books* and a *Scrole* of *Parchment* under his Left Foot, on his Right Knee a *Book* opened; the Figure standing by *Judgment*, is *Logick*, and points towards the opened *Book*: The Building is the prospect of a *Theatre*, the *Books* and *Serpents* under, are the Emblems of *Learning* and *Wisdom*, the inseparable Companions of *True Judgment*, who is represented elderly, as a Badge of *Experience*, and placed in the *Clouds* to shew his inspection of all Human Affairs; and the various Colours of the *Rainbow* he sits on, denote the various Methods he makes use of to be informed, and the brightness of its *Rays*, the clearness of his apprehension, and the seeming information given him by *Logicks*, pointing to the *Book*, shews the necessity of *Learning*, to enable us to make a true Judgment.

REASONING, Part 1. Chap. 15. fol. 33. Represented by an elderly *Woman*, sitting on a *Pedestal*, leaning her Head on her Left Hand, with *Books* under her Left Foot and Elbow, in her Right Hand a *Book* a little opened, her Forefinger therein, and a *Scrowl* hanging from below the *Book*, with this Motto, *in perfecto quiescit*; the Figure

An Explanation of the Sculptures.

standing in a *Glory*, incircled with *Clouds*; and on which *Reasoning* seems to have her Eye, represents *Truth* holding a *Book* in her Right Hand, and a Branch of *Palm* in her Left, having the *Globe* of the *Earth* under her Foot: On the Fore-ground are *Boys* and *Books*. The Motive for representing *Reasoning* by these *Figures*, are these, 'tis represented by a *Woman*, to denote its productive Faculty, right *Reasoning* being the common *Mother* of every great *Good* and wise *Action*; the *Books* under her Foot, denote some doubts she hath long since overcome; and those under her Elbow, some doubts just removed; her melancholy *Posture* and *Air*, shew the necessity of seriousness in *Reasoning*; the *Book* in her Right Hand, seems to contain (and more especially that part which she engageth with her Forefinger) what is exprest in the *Scrole* that hangs from it, which is, that by the help of *Reasoning* we may bring all our undertaking to that perfection as will afford the means of being at rest: The placing *Truth*, as in the description, is to shew, that *Reasoning* hath always *Truth* in view, that being the End she aimeth at; the *Glory* incircled with *Clouds*, exprest the inward Beauties of *Truth*, tho' sometime vail'd with *Clouds* of Ignorance; the *Book* and *Palm* which occupy her Hands, are Emblems of those *Goods* she gives her Possessors, Peace and Knowledge; and her Foot being placed upon the *Terrestrial Globe*, denotes her excellence above all earthly things.

CONTEMPLATION Part 2. *Introduction*, fol. 53. The *Sculpture* represents a *Woman* kneeling at her Devotion, having beneath her the *Globe* of the *Earth*, with Eyes covered, holding a *Scepter* in her Right Hand, and on the same side, the *Sun* in *Glory*; and on her left side the *Moon* and *Stars*, which she seems to inspect with care; above in the *Clouds*, the *Glory* of the Supreme Deity, with the word *Jehovah*, environ'd with Blessed *Spirits* in postures of Adoration: She is placed above the *World*, to shew that those who seriously contemplate the *Glory* of *GOD*, must be contemnors of the *World*, and have their Eyes, like hers, vail'd to all its Inducements, flattering Joys and Temptations; her *Scepter* denotes the power of heavenly Contemplation, we being thereby made more than *Kings* and *Conquerors* (according to the Scriptures;) her contemplating the *Sun*, *Moon* and *Stars*, shews that whosoever soberly considers the wonderful Creation of those *Glorious Bodies*, will think their time best employ'd in contemplating with Gratitude and Wonder the Excellence and Power of that *GOD* who made them.

FATE and WILL Part 2. Chap. 5. fol. 62. The *Figure* on the Right Side with folded Hands, and clad in a full Garment, is *Fate*; his folded Hands are Emblems of Unchangableness, and his full Garment resembles his Amplitude; the Golden Chain which seems to fall from the *Star* in *Glory*, on which *Fate* looks, and with which both he and the other *Figure* who represents *Will*, are incircled, shews the necessity of the *Wills* complying with *Fate*, being bound thereto with a Chain of Coelestial Causes; the Wings of *Will* are Emblems of her swiftness; and her extended and erected Hands and Head towards Heaven, shews we will every thing under the appearance of *Good*.

PROVIDENCE, Part 2. Chap. 16. fol. 74.

Represented by a *Woman* sitting on a *Pedestal*, her Right Arm leaning on a *Wheat-sheaf*, and on her Left a *Boy* winged, bringing her a *Cornucopia* of Fruits and Flowers, as shewing the great goodness of *Providence*, who gives not only on the Right, Corn to support the necessity of Nature, but also on the Left, Fruits and Flowers to recreate and cherish it: At a distance in prospect is a *Corn-field*, in reaping time, brought to its maturity by that *Eye* of *Providence*, which from out of a *Glory* inspects it, and thereby demonstrates that *GOD* in his *Providence* vouchsafes to look down from his all *Glorious Throne* of Heaven to bless the *Goods* of the *Earth* to Mans use, which ought to draw from us returns of *Praise* and *Thanksgiving*.

SPIRITS, Part 3. *Introduction*, fol. 76. In the *Clouds* are represented *Choirs* of blessed *Angels* playing on *Musical Instruments*, and singing and praising *GOD*. In a *Cavern* below, are represented the *Infernal Spirits*, seeming to utter hideous *Cries* and *Groans*, the effects of the anguish they suffer in themselves, and that raised in them by their enviously beholding the happiness of the Blessed above; for true Happiness is by nothing so much exprest as by praising *GOD*.

NATURE of ANGELS, Part 3. Chap. 1. fol. 77. In the *Clouds* appears a *glory* of *Angels* and *Cherubims* contemplating with desire and joy, the *Glory* of *GOD* which appears above, half veild by a *dark Cloud*; it being the Nature not only of *Angels*, but of all good Men to behold with *Praises* and *Adoration* that *GOD* who made them for that end.

MOTION of ANGELS Part 3. Chap. 5. fol. 82. Represented by several *Angels*, occupying themselves in doing the service acceptable to their Creator, as bringing *Peace* and *Reward* to the *Good* on *Earth*, which is shewn by those two, who bear a *Coronet* and *Branch* of *Palm* downwards, as likewise in carrying the *Actions* and *Prayers* of the *Just* to Heaven, shewn by that *Angel* who bears the *Pot* of *Incense* towards the *Sky*; and by the other who is uncovering the Monument of *King Charles* the Second, to lay, as it were, open the good *Actions* of that best of *Princes*, to that *GOD* who will reward them.

ORDER NUMBER and DISTINCTION of ANGELS, Part 3. Chap. 6. fol. 83. The *Sculpture* represents the three *Hierarchy* of *Angels*, and in each *Hierarchy* the three *Orders*; the 1st. containing *Seraphims* *Cherubims* and *Thrones*, the 2^d. *Dominions*, *Virtues* and *Powers*; the 3^d. *Principalities*, *Arch-Angels*, and *Angels* with *Palms*, *Swords* and *Crowns*, denoting their *Offices* of *Peace*, *Power* and *Glory*, given them by that *GOD*, who is represented above them, and who made, ordered, numbr'd and distinguished them for his *Service* and *Glory*.

DEMONS, Part 3. Chap. 10. fol. 88. In a gloomy *Cavern* are represented the nine degrees of *Demons*, or *Infernal Spirits*, distinguished by their monstrous and ugly variety, and which (according to the Discourse) they are known by: The first termed *Belzebub*, generally allowed Sovereign *Emperor* over all the rest, tho' his Name signifies no more than *King* of *Flies*; the 2^d. *Python*, 3^d. *Belial*, 4th. *Asmodeus*, 5th. *Satan*, 6th. *Meririn*, 7th. *Apolyon*, 8th. *Astorath*, and 9th. *Mammon*: The *Figures* in the *Air* are *Angels*, bearing up a *Child*

An Explanation of the Sculptures.

Child, whom they had rescued from the *Devils*: The reason for the precedency of these *Devils* to one, the other ariseth from their greater or lesser power in doing hurt, and therefore some people may wonder why *Mammon*, who is taken for the *Devil* of *Riches*, should be placed last, the power of *Gold* in doing ill being the greatest.

CARE of ANGELS, Part 3. Chap. 1. fol. 89. Represented by an *Angel*, rescuing and protecting a young *Man* from the fury of the *Devil*, and by two *Angels* driving a *Dæmon* before them, the defending us from the assaults and snares of the *Devil*, and driving him from us, being their constant employment and care.

PHISICKS, Part 4. Chap. 1. fol. 91. Represented by a *Woman* with a *Sphere* and *Books*; on her Right Side an *Eagle*, and on her Left two *Boys*, having a pair of *Compasses* and a *Square*; the three *Figures* in prospect are three *Philosophers* in consultation concerning the *Planets* and *Stars*, the *Books*, *Mathematical Instruments*, and *Eagle* are Emblems of the quicksightedness, Learning and Practice requisite to the true understanding of *Phisicks*.

DURATION and TIME, Part 4. Chap. 24. fol. 131. *Time* is represented by *Saturn*, being an Old *Man* bald Headed except one *Lock*, and standing on Tiptoe with one Foot on a *Rock*, having a *Sybh* and *Hourglass*: *Saturn* is feigned by the *Poets* to be the Father of the *Gods*, the first beginner of *Time*, his Age and Bald-pate denote his antiquity and duration, and his one *Lock*, the one punctum of *Time* present, by which we ought to hold; he stands on Tiptoe to shew he hastens to be gone; his *Hourglass* and *Wings* are Emblems of his never resting and swiftness, and the *Sybh* the destruction and consumption he makes of all things. The four *Figures* below him, represent the four *Seasons* of the *Year* and parts of *Mans* Life, following one another towards the *Temple* of *Eternity*; our *Childhood* brings *Youth*, *Youth* brings *Manhood*, *Manhood* Old Age, and Old Age to that *Eternity* properly described by the *Circle* over the *Temple*, and the *Hoop* in the *Boys* Hand, being what are in appearance without end.

The Motion of the PLANETS, Part 5. Chap. 1. fol. 134. Represented by *Sybell*, having a *Castle* on her Head, and sitting on *Lions*, placed on the *Globe* of the *Earth*; the *Castle* and *Lions* denote the strength of the *Earth*, both in respect to its *Creatures* and *improvements*, the *Lion* being the strongest *Animal* made by *Nature*, and a *Castle* the strongest thing made by *Art*; her having the *Castle* on her Head, and the *Lions* below her, shew the strength of *Human Art* is greater than the strength of *Beasts*; the seven other small *Figures* are bodily representations of those *Poetical Heathen Gods*, whose Names are made use of to distinguish the *Planets* by; that in the midst and over the *Earth*, is *Apollo*, encircled with *Light*, as *God* of the *Sun*; his *Bow* and *Arrow* denote the piercing power of his *Rays* and *Sun-beams*: That standing on a *Cloud*, and under the *Earth*, is *Luna*; the *Bow* in her Hand, and *Cressent* on her Head, are Badges of her two-fold *Divinity*; the first as she is Goddess of *Hunters*, by the Name of *Diana*; the last as Goddess of the *Moon*, by the Name of *Luna*, as above: The *Figure* over *Apollo*, is *Mercury*, the *Wings* of his Feet denote his swiftness in running, as his *Staff* twisted with *Snakes* doth his Cunn-

ing; those being the peculiar Excellencies given him by the *Poets*, and the Qualifications that rendered him capable of the great Employments he possesseth, of being *Envoy* and *Carrier* in Ordinary to the *Gods*: The *Figure* on the Right Side of *Apollo*, is *Venus*, the *Star* on her Forehead denotes her *Divinity*; her *Doves* are Emblems of *Love*, and properly joined to her who is the Goddess of *Love*. Over *Mercury* stands *Mars*, who bears a *Sword* and *Buckler*, being accounted the *God* of *War*; that on the Left Hand is *Jupiter*; the *Thunderbolts* in his Hand, and the *Eagle* under him are the *Coat Armour* of *Heaven*, of which by the same Authority, he is accounted *God*: That on the Right Side is *Saturn*, his *Wings* denote the fleeting of *Time*, of which he is reported *God*, and the *Sybh* in his Hand, shews the destruction made of all things by this *Divinity Time*.

The SUN in GLORY, Part 5. Chap. 14. fol. 157. Within a *Glory* is represented, *Phæbus* in his *Chariot* drawn by white *Horses*, they being the *Creatures* he is said to have ordered to be offered up to him in *Sacrifice*; beneath lies a *Shepherd* and his *Dog* a sleeping, who are recovered from their drowsiness by the brightness of his *Rays*, and the warmth of his *Beams*, which cherish and enliven all *Human Creatures*.

The MOON, COMETS, &c. Part 5. Chap. 17. fol. 162. The *Figure* covering his Eye with his Finger, is *Archimedes* a viewing the *Moon*, *Stars*, and other *Planets*, through a *Teliscop*; and that *Figure* next him is a *Philosopher* discoursing him about some *Planetary Observations*; upon and below the *Table* are several *Mathematical Instruments*, as *Squares*, *Globes*, &c.

The EARTH, Part 6. Chap. 1. fol. 179. Represented by *Sybell*, drawn by *Lions* in her *Chariot*, having a *Castle* on her Head, and the *Globe* of the *Earth* beneath her: The reason for representing the *Earth* by this *Figure*, is given before in the *Treatise* of the *Motion* of the *Planets*: The *Angel* bearing *Fruits* and *Flowers*, as it were from *Earth* to *Heaven*, denotes that the sweetest things of the *Earth* ought to be offered up to the *GOD* of *Heaven*, who made and preserveth the *Earth*.

DAY and NIGHT, Part 6. Chap. 5. fol. 187. The *Figure* of the *Young Man* with *Wings* holding a lighted *Torch* in his Right Hand, and a *Serpent* in a circular form in his Left, having one Foot on a *Cloud*, and the other on the light part of the *Globe*, represents *Day*; his Youth is the *Morning*, and his lighted *Torch* the *Noon*; his circular *Serpent* shews the motion of *Time*, and his treading on a *Cloud*, that he puts *Darkness* under his Feet; behind the *Globe* on the backside, slipping away as it were, stands a *Woman* Winged and Cloathed in a *Sables Garment*, embroidered with *Stars*, having on her Head a *Crown* of *Poppeys*, representing *Night*; her Posture shews her not to be able to stay in presence of *Light*; her *Garment* is her proper Emblems, and her *Poppeys* are promoters of *Sleep*, the true business of the *Night*: The Element below her spangled with *Stars*, shews the descending of *Night* at the ascending of *Day*.

The WATER, Part 6. Chap. 11. fol. 202. Represented by *Thetis*, whom the *Poets* have fain'd to be Goddess of the *Sea*; her *Chariot* is drawn by *Dolphins*, accounted the best natured and most compassionate *Fish*; and for that reason preferred to the honour

An Explanation of the Sculptures.

honour of drawing their *Queen*: Over her is the *Figure* of a *Boy*, who pours *Water* out of a *Watering pot*, as intimating that we have *Water* from above in *Rain*, as well as below in *Rivers*.

The AIR, Part 6. Chap. 13. fol. 207. Represented by the Goddess *Juno*, Wife of *Jupiter*, sitting in a *Charriot* drawn by *Peacocks*; she is accounted by the *Poets* as Goddess of the *Air*, and is drawn by these *Birds* as the most beautiful *Creatures*, to compleat whose beauty, she hath adorned their *Tails* with a hundred refulgent *Eyes*, taken from *Argus*, to whom she had given them, the better to see into the Amorous Intreagues of her Husband *Jupiter*, of whom she was Jealous, but *Argus* being kill'd by *Jupiter*, she reassumed her Gift and disposed of them as above.

The WIND, Part 6. Chap. 16. fol. 211. Represented by a *Figure* Crown'd and Sceptr'd, being *Aeolus*, the Poetical God, and King of the *Winds*; on each side of him are two *Figures*, representing the four *Winds*; the lowest on the Right Hand is *Boreas*, the North wind, depicted like an Old Man, with *Bats Wings* and a *Serpents Tail*; his *Bats Wings* denote his blowing most in *Evenings* and *Nights*, and the *Serpents Tail* his flinging *Colds* and *Blasts*; above is *Eurus* the East-wind, represented also by a *Man* with *Wings*, to shew the swiftness of his motion: The uppermost on the Left Hand is *Anster*, the South-wind, represented by a *Young Man*, and below him *Zephyr*, the West-wind, represented by a *Man* pouring out *Water*, as generally bringing *Rain* along with him; they are all blowing out *Winds*, which occasions a *Tempest*, as appears by the foaming and raging *Billows* of the *Sea*, that seem to overwhelm the *Ships* therein.

THUNDER, Part 6. Chap. 19. fol. 217. Represented by *Jupiter*, who, as before is said, is accounted the chief God of *Heaven*, and the Inventer and User of *Thunderbolts*, having as 'tis storied, been forc'd to contrive this *Weapon* to defend his Celestial Kingdom against the assaults of the *Giants*, who dared to attempt the Invasion of it; they are made by *Vulcan*, the Black-Smith in Ordinary to the *Gods*, and accounted as such himself, and are of that subtle contrivance, that they at once *kill*, *burn* and *astonish* without being seen; for which reason there is no Guard to be made against them; he is set upon an *Eagle*, the Emblem of Quickflight and Power; for as that *Bird* only can gaze on the *Sun* with unmoved *Eyes*, and destroy with her strength whom she pleases of the *Birds*, so *Heaven* only has power to discern our *Actions*, and to punish where it thinks fit: The *Figures* below represent two *Men*, covering their Heads for fear of the *Thunder*, and affrighted at its noise; the *Houses* on *Fire*, the *Trees* *Blasted* and beaten down are the visible effects of *Thunder*, and may admonish us to beware of offending *Heaven*, who can destroy with its Breath.

The FIRE, Part 6. Chap. 21. fol. 221. Represented by *Vulcan* standing in his *Charriot*, which is drawn by *Sea-dogs*, at work at an *Avil*, being furnished with *Fire* from *Mount Aetna*. *Vulcan* is the fam'd Blacksmith to the *Gods*, as is before said, and consequently a great Dealer in *Fire*; the two *Sea-Dogs* chained to, and drawing his *Charriot*, are Emblems of the predominancy that *Fire* hath over its contrary Element the *Water*; and by *Mount Aetna* is shewn the power of this hot Element even in the *Earth*.

ANIMALS in general, Part 7. Introduction, fol. 229. In the midst a *Man* contemplating with admiration the variety of *Beasts* and *Fowls* about him.

GARDNING, Part 7. Chap. 12. fol. 245. The representation of a *Garden*, in which the four *Figures* are *Gardners*, imployed in so many several *Actions* belonging to that Ingenious Art, as *Digging*, *Grafting*, *Inoculating* and *Screening* of *Earth*; in prospect a *Fine House*.

ANIMALS, Part 7. Chap. 17. fol. 252. The representation of several *Animals*, and more particularly those extraordinary in their kind, as the *Horse*, *Elephant*, *Lion*, *Camel*, *Deer*, *Bear*, *Swine*, *Sheep*, *Dog*, &c.

CREEPING THINGS, Part 7. Chap. 19. fol. 256. Represented by a *Tortoise*, *Crocodile*, *Lizard*, *Serpent*, *Mole*, &c.

FOWL or *FLYING ANIMALS*, Part 7. Chap. 20. fol. 257. Represented by the *Ostridge*, *Eagle*, *Peacock*, *Swan*, *Turkey*, *Cock* and other *Birds*.

FISH or *SWIMMING ANIMALS*, Part 7. Chap. 21. fol. 259. Represented by the *Salmon*, *Pike*, *Lobster*, and other *Fish*; in prospect some *Men* in *Fishing Boats*, and *Nets* a catching *Fish*.

INSECTS, Part 7. Chap. 22. fol. 261. Represented by several sorts of *Butterflies*, small and great *Flies*, *Grashoppers*, &c.

MAN as to his *BODY*, Part 8. Chap. 1. fol. 264. The *Figures* represent *Man* in his compleat *Body*, composed by *Bones*, *Flesh* and *Skin*: That on a *Pedestal* on the Left, is perfect, the next is the *Muscular*, having his *Skin* off, and the next an *Anatomy* of *Human Body*; the *Figures* seeming to inspect them, represent *Physicians* as consulting.

The five *SENSES* in general, Part 8. Chap. 10. fol. 283. 1st. *Smelling*, represented by the *Figure* holding a *Flower* to her *Nose*. 2^d. *Hearing*, represented by a *Young Woman* playing on an Instrument of *Musick*. 3^d. *Tasting*, represented by a *Young Woman* filling a *Glass* of *Wine*, and by her side a *Monkey* eating an *Apple*. 4th. *Feeling*, represented by a *Woman* pulling a *Snake* from her *Hand*, and by two *Cocks* fighting. 5th. *Seeing*, represented by a *Woman* in a *Habit* of a *Falconer*, having a *Hawk* on her *Fist*, ready to be cast off at that *Bird* in the *Air* which she seems to view.

FEELING, Part 8. Chap. 12. fol. 286. Represented by a *Woman* seeming to snatch her *Hand* from a *Parrot*, who seems to bite it; at the same time a *Dog* is pulling her by the *Coat*; as also by that feeling story of the *Monkey* making use of the *Cats* *Paw* to pull the *Chestnut* out of the *Fire*; and by a *Mans* beating a *Dog*, and by the fighting of two *Birds*, all true Emblems of this noble *Sense*.

TASTING, Part 8. Chap. 13. fol. 288. Represented by two *Women* in a *Garden*, the one seated and eating an *Orange*, expressing by her gay *Air* the pleasure afforded her by that noble *Sense*; the other is the *Figure* of a *Woman* pulling some *Fruit* in order to eat it; there are also *Cupids* eating *Oranges*, to shew the pleasures of *Love* consist chiefly in *Tasting*.

SMELLING, Part 8. Chap. 14. fol. 290. Represented by two *Women* in a *Flower Garden*, and smelling the *Flowers*: By a *Blood-bound* in *Scent* after his *Game*; as likewise by an *Incense Pot* smocking with *Perfumes*, being the most pregnant Emblems of that *Sense*.

HEARING, Part 8. Chap. 15. fol. 292. Re-

An Explanation of the Sculptures.

Represented by a *Woman* playing on an *Organ*, having two *Women* standing behind her, with *Musick-Books* in their *Hands*, and seeming to sing in consort; and by a *Cock* pearching on a *Pedestal*, being the Creature who hears at a greater distance than any other.

SEEING, Part 8. Chap. 18. fol. 297. Represented by a *Man* with a *Prospective* in his *Hand*, standing on a *Hill* viewing an *Ingagement* of *Ships* at some distance, and by a *Figure* lying on the fore-ground, having his *Eyes* fixt on the *Sea*, which seems at a distance.

MEDICIN, Part 8. Chap. 24. fol. 315. Represented by the *Serpent Python*, surmounted by *Apollo*, the *God* of the *Sun*. This *Serpent* is said to *Poison* all the *Herbs* and *Grass* he comes near, and for that reason was destroyed by *Apollo*, who also is the *God* of *Wisdom*, and properly Emblemiseth *Medicin*, there being, in wisely prepared *Medicins*, a remedy to destroy all poisonous *Diseases*.

MAN as to his MIND, Part 9. Chap. 1. fol. 320. The *Womanish Figure* holding a *Sphere* in her *Right Hand*, and a *Glory* descending from *Heaven* upon her *Head*, represents a *Human Soul*; the *Sphere* is the Emblem of its *knowledge*, as to *Human Affairs*, the descending *Glory*, its *Immortality*; on her *Right Hand* stands *Knowledge*, represented by a *Woman*, who holds a *Torch* lighted in her *Right Hand*, an open *Book* on her *Lap*; and on the *Left Hand* is the *Figure* of a *Man*, sitting in a musing posture, having *Wings* on his *Back*, and represents *Thought*; she is thus attended to shew that the two noblest *Faculties* of the *Soul* are *Knowledge* and *Thinking*.

The **FACULTIES of the MIND**, Part 9. Chap. 5. fol. 328. The four *Figures* represent the four *Faculties*. 1st. *Understanding*, represented by a *Young Man*, to denote the *Beauty* of it, *Robed* and *Crown'd* to shew that *Honour* and *Power* attend it; and the *Flame* encircling the *Head*, is an Emblem of its alliance to *Heaven*, and the *Eagle* is an Emblem of its quickness in perceiving. 2^d. On the *Right Hand* of *Understanding* stands *Imagination* represented by a *Woman*, to shew its productive *Power*, which is also shewn by the *Coronet* of small *Figures* she bears on her *Head*; *Imagination* producing more various forms and beings than *Dame Nature* can boast of; the *Wings* on her *Head* denote the swiftness of that *Faculty*. The 3^d. is *Memory*, represented by a *Woman* with a *Helmet* on her *Head*, to shew the strength of that *Faculty*; and by her a *Dog* in a *Slip*; a *Dog* is a proper Emblem of *Memory*, enjoying, as by *Experience* is found, more than any other Creature, of that noble *Faculty*. The 4th. is *Will*, represented by a *Young Man* *Wing'd* and *Blindfolded* with extended *Arms*, and erected *Head*; the reason for representing that *Faculty* is given before.

ADMIRATION, Part 9. Chap. 9. fol. 335. Represented by a *Woman*, seeming to have all her *Faculties* at work, by viewing that admirable Object that lies before her, being a *Lion* and a *Lamb* lovingly enfolded, and by other *Figures*, whose *Looks* spake this *Passion*; in prospect, a *Building*.

LOVE and Hatred, Part 9. Chap. 10. fol. 337. Represented by *Venus* the *Goddess* of *Love*, sitting in the *Clouds*, and over her *Cupid* her *Son* and *Messenger*; the *Arrow* he holds in his *Hand*, is the *Weapon* that opened the way for the *love* of the *Man* below, to the *Heart* of that *Lady*, who seems to embrace him: The *Figure*, as it were stabbing the other with a *Dagger*, represents *Hatred*, and the *Devil* behind him shews the ugly and damnable qualities of that *Vice*.

AFFECTIONS or DESIRE, Part 9. Chap. 11. fol. 338. Represented by a *Young Woman*, who in the per-

suit of *Honour* and *Riches*, which seem to appear to her at a distance, is thrown down by the *Figure* of *Will*, (represented as usually) and at the same time a *Serpent* bites her by the *Heel*, shewing the misery and pain which attend the desiring or affecting too much above what we want, to sustain *Nature*, and the *Precipice* we are hurl'd from by our *Will*, in placing our *Affections* on those *Goods* of *Fortune* which are not in our reach.

JOY, Part 9. Chap. 12. fol. 339. Represented by a *Young Woman*, in a loose *Garment*, having a *Bottle* of *Wine* in one *Hand*, and a *Glass* in the other; by her another *Figure* with a *Bottle*, and on the fore-ground *Boys* playing on *Flutes*: This *Passion* is most properly thus emblemised, *Women*, *Wine*, and *Musick* being the *Joy* *Heaven* gave us to guild this otherwise bitter *Pill* of *Life*.

SADNESS, Part 9. Chap. 13. fol. 340. Represented by a *Woman* in a *Widows* habit, sitting on the ground in a melancholy posture, leaning her *Head* on her *Hand*; by her a *Boy* a weeping, and below her a *Boy* with an extinguished *Torch*; above, and at some distance from her, stands an *Urn* impaled with *Cypress Trees*; upon the *Rails* which encompass the *Pedestal* of the *Urn*, stand *Pots* of *Fire* flaming, to the memory of him whose *ashes* are contained therein: These *Figures* are the properest Emblems of this *Passion* of *Sorrow*, no state being so void of *Joy* as hers, who being a fond and virtuous *Wife*, is by death robbed of a deserving tender *Husband*; the darkn'd *Torch* held near her, shews she has no flame, but that which burns to the *Manes* of her departed *Lord*.

ETHICKS, to front Part 10. fol. 346. Represented by a *Woman*, seated in a graceful Posture on an ascent, holding a *Lion* bridled in her *Left Hand*, and in her *Right a Level*; her ascent and graceful Posture, shew the Majesty of this Noble part of *Philosophy*; her bridled *Lion* denote its *Power*; the force of her Arguments in evincing and clearing, are shewn by her *Level*: On her *Right Side* are the three *Cardinal Virtues*, *Truth*, *Justice* and *Charity*; the first represented by a naked *Figure*, holding a *Book* and *Palm Branch* in one *Hand*, and the *Sun* in the other: 'Tis naked, to shew *Truth* ought not to be covered; her *Book* and *Palm* are the rewards she gives, which are *Peace* and *Knowledge*; and the *Sun* is an Emblem of her *Brightness*, *Truth* being as clear as the *Noon Day*: The 2^d. is represented by the *Figure* of a *Woman* veiled, holding a *Scepter*, with an *Eye* upon the top, in her *Hand*; she is veiled, to shew she looketh not on, nor regardeth the *Person* of any, but administers *Justice* impartially; her *Scepter* and *Eye* denote her *Power* and *Knowledge*: The next is *Charity*, represented by a *Woman* comforting *Children*; on the *Left Side* of *Ethicks* stand the four *Vices*, *Envy*, *Drunkenness*, *Lasciviousness* and *Deceit*. The 1st. *Envy*, is represented by an *Old Woman* half naked, having *Snakes* about her *Body* and *Hair*; *Age* and *Snakes* are the proper Emblems of this *Vice*, it being as old as the *Devil*, and poisoning the *Minds* of all that entertain it, as *Snakes* do the *Bodies* of all that touch 'em. The 2^d. *Drunkenness* is represented by a *Man* a *spewing*, the true loathsome Emblem of that *Gluttonous Vice*. 3^d. *Lasciviousness* represented by a *Woman* in an immodest posture, that being *Lasciviousness*. 4th. *Deceit*, represented by a *Woman* holding a *Mask*, shewing the necessity that *Vice* hath of being disguised, and of its often appearing under borrowed forms: *Ethicks* is thus attended to shew the *Virtues* she possesseth, and the *Vices* she hath overcome.

The **HIGHEST GOOD**, Part 10. Chap. 3. fol. 350. Represented by a *Young Man*, cloathed in a short *Garment*, with his *Eyes* lift up towards *Heaven*, holding in one *Hand* an *Olive Branch*, and in the other a burning *Heart*, into which his *Tears* seem to fall, and on his

An Explanation of the Sculptures.

Head the *Glory* of *Heaven* descending, as through a *Cloud*: The highest *Good* consists in these three things, peace of *Mind*, the favour of *God*, and a Heart flaming with desire of *Heavenly things*; and therefore 'tis properly represented by this *Figure*.

The LAW of NATURE, Part 10. Chap. 8. fol. 356. Represented by a *Young Woman* half naked, having her lower parts covered with a *Lamb-skin*, Emblems of that innocence and modesty prescribed by *Natures Law*; she is placed in a pleasant *Garden*, holding a *Table* on her *Knee*, and a pair of *Compasses* in her *Hand*, measuring two *parallels*, with this Motto *Aqua lance*; behind her a *Woman* holding *Books*, and having other *Books* under her *Feet*; all which denote how even just and pleasant the *Laws of Nature* are: On her *Right Side* are the three *Virtues*, *Truth*, *Justice* and *Charity*; and on her *Left Side*, *Envy*, *Drunkennes*, *Malice* and *Pride*, all properly Emblematis'd as before; by the *Virtues* being on the *Right of Nature*, and the *Vices* on the *Left*, we are taught that *Virtue* is more acceptable than *Vice* to *Nature* in her first *Principles*, till she is deraught by *Custom* or *Practice*.

PRUDENCE, Part 10. Chap. 9. fol. 359. Represented by a *Woman*, standing in a graceful posture, holding in her *Right Hand* a *Looking-glass*, and in her *Left* a *Serpent*; and over her an *Angel* putting an *Helmet* on her *Head*; on her *Right Hand* a *Cupid*, holding an *Olive Branch* in one *Hand*, and a *Palm* in the other; and on her *Left Side* a *Young Man* with a *Sword* and *Buckler*: The *Looking-glass* in her *Right*, denotes that every prudent *Person* ought to look into, and know themselves; the *Serpent* is an Emblem of *Cunning*, and the *Angel* putting the *Helmet* on her *Head*, expresseth *Heavens* aiding us in all our prudent undertaking: The *Cupid* with *Branches*, and the *Young Man* Armed, denote that *Prudence* brings success in *Love*, and *Victory* in *War*.

TEMPERANCE, Part 10. Chap. 10. fol. 361. Represented by a *Woman*, holding in her *Right hand* a *Bridle* to curb the exorbitant desires of the *Flesh*, and over her *Head* an *Angel*, crowning her with *Lawrels*, having a *Palm* in his *Hand*, thereby shewing that *Heaven* will reward this *Virtue* with *Peace* and *Glory*; on her *Right* a *Cupid*, pouring out *liquor* in a *Vessel*, and on her *Left* an *Elephant*, dividing his proportion of *Corn*, denoting thereby that we must use *Temperance* even in *Love*, and that *Beasts* share in that *Virtue* which men must blush to want.

FORTITUDE, Part 10. Chap. 11. fol. 363. Represented by a *Woman*, holding a *Pillar*, and curbing with a *Bridle* a *Lion*, who seems enraged: In the *Air* is represented *Hercules* with his *Club* and *Lions Skin*; the story of *Hercules*, and the reason for his being so adorn'd is so little estranged, that it needs not be here repeated; therefore I shall only add, that the Emblems of *Corporal Fortitude*, as here described, serve only to enable us to judge of the greater *fortitudes* of the *Mind* discours'd of in the *Book*.

JUSTICE, Part 10. Chap. 12. fol. 365. Represented by a *Woman*, holding in her *Right Hand* a *Sword*, and in her *Left* a pair of *Scales*; next her a *Boy* bearing the *Fasces* and *Axes* carrying before the *Roman Victors*: The *Figures* of the *Men* represent *Philosophers* contemplating *Justice*, that being the work of every wise *Man*; the *Fasces* were *Rods*, with which they used to chastise *Malefactors* for small faults.

MANS DUTY to GOD, Part 10. Chap. 23. fol. 382. Represented by a *Man*, *Woman* and *Boy*, addressing themselves to *Heaven*, in a becoming posture, and in the *Clouds* two *Angels* with *Trumpets*; 'tis represented by these three, to shew that *Men*, *Women* and *Children* are obliged to this *Duty*; the *Angels* with *Trumpets*, de-

note the joy the *Blessed* have in beholding the *Righteous Actions* of *Men*; the *Angel* below pointing to the *Coronet* and *Cornucopia*, is an Emblem of that *Honour* promised to the *Righteous*; the *Flame* three-fold, flaming on the *Womans Head*, denotes by its number the *Trinity*, by its heat, the warmth of her *Zeal*, and by its light, the brightness of her *Faith*.

MANS DUTY to HIMSELF, Part 10. Chap. 24. fol. 384. Represented by an *Old Man*, in a becoming posture, holding in his *Right Hand* a *Staff*, having a *Serpent* twisted about it, his *Head* Crowned with *Lawrel*; on his *Right Side* a *Young Man* armed, having on his *Head* a *Helmet*, in his *Right Hand* a *Sword*, and in his *Left* a *Target*; self-preservation is every *Mans* duty to himself, and therefore provident *Nature* hath furnish'd the means; to the *Old* she hath given *Cunning* to save themselves, emblematis'd by the *Old Mans Staff*, encircled with *Serpents*, the cunningest and most subtle of *Creatures*; to the *Young*, strength and valour, represented by the *Sword* and *Target*, held in the *Young Mans Hand*, whilst the *Figure* of *Justice*, who stands before them both, informs us that both *Old* and *Young* are obliged to be just, not only to others, but to themselves.

MANS DUTY to his NEIGHBOUR, Part 10. Chap. 25. fol. 385. Represented by two *Men* kindly embracing each other; on their *Right Side* are *Justice*, *Love* and *Charity*, with their proper Emblems as before described; and on their *Left*, a *Woman* with a *Cornucopia* of *Fruits* and *Flowers*, the Emblem of *Plenty*; all which denote, that we ought to be friendly in our carriage, just in our dealings, and charitable (according to our ability, to all that want) and that those who do so, shall have plenty of all the *Fruits* of the *Earth*.

CONTRACTS, Part 10. Chap. 27. fol. 387. Represented by the Platform of a *Custom-house Key*, with *Figures* of several *Men*, denoting a *Merchant*, a *Chapman* and *Porter*; in a *Barge* a *Man* stowing some goods, which they seem to have contracted for.

MUTUAL FAITH or MARRIAGE, Part 10. Chap. 32. fol. 395. Represented by the *Figure* of *Faith*, being a *Woman* almost naked, having a *Glory* about her *Head*; her nakedness denotes her *innocence*, and the *Glory* is the Emblem of that *Heaven* from whence she sprung; she is placed between a *Man* and *Woman*, joining *Hands* as in *Marriage*, to shew that she only can truly perform that *Office*: On the *Mans* side is the *Figure* of *Justice*, an emblem of what he owes to his *Wife*; and on the *Womans*, that of *Constancy*, and a *Cupid* with a lighted *Torch*, denoting that the *Duties* of a *Wife* to her *Husband* are constant *Love* and *Desire* towards him; the *Torch* is a *Badge* of the ancient way of performing that Ceremony of *Marriage*, for on the *Wedding-day* they used to light up a considerable number of them, in honour to *Hymen* the *God* of *Marriage*; the billing *Turtles* are emblems of that *Love* and *Harmony* which ought to be between *Man* and *Woman*.

DUTY of PARENTS and CHILDREN, Part 10. Chap. 33. fol. 396. Represented by a *Man* and *Woman*, sitting in a grave and loving posture, having *Children* about them; by their side is the *Figure* of *Justice*, having her *Head* covered with a *Helmet*, and a *Mound* under her *Foot*, to denote that the *Duty* of *Parents* is giving good example to their *Children*, and that their *Justice* ought to take place and surmount all paternal fondness; on the *Right Side* is the *Figure* of a *Woman* veil'd, representing the modesty *Children* must observe in the presence of their *Parents*; the *Stork* by her Side is the emblem of ill *Parents*, it being reported of that *Bird*, that she eats her *Young Ones*.

DUTY of MASTERS and SERVANTS, Part 10. Chap.

An Explanation of the Sculptures.

Chap. 34. fol. 397. Represented by a *Woman*, sitting in a graceful posture in a *Chair*, attended on the Right Hand by a *Woman* holding a *Garland* and *Cornucopia*, representing *Plenty*; and on the Left by a *Woman*, bearing a *Sword* and *Balance*, the emblem of *Justice*; before the *Chair* stands a *Blackamoor* Lackney, seeming to receive some *Errant* to go on; beneath the *Figure* of *Plenty* stands a *Maid-servant* attending her *Ladies* Commands, all which properly describe that *Masters* and *Mistresses* are bound in duty to do *Justice* to, and provide for their *Servants* plenty, and that the duty of *Servants* is the careful, honest and respectful performance of all their *Masters* or *Mistresses* lawful Commands.

REGAL POWER, Part 10. *Chap. 35. fol. 398.* Represented by a *Man*, seated on a *Throne*, *Crown'd*, *Rob'd*, *Scepter'd*, with a *Mound* in his Left Hand, attended on by his *Courtiers*, as also by the representations of *Justice*, *Prudence*, *Clemency*, *Fortitude* and *Truth*, as the eternal *Companions* of true *Regal Power*; he being no more properly a *King*, who wants these *Virtues*, than an illiterate *Man* can be a *Judge* of *Learning*.

The Explanation of the Sculptures in the HISTORY of NATURE, Book II.

THE FRONTICEPIECE, represented by a *Woman* looking behind her, and writing in a *Book*, which lies on the Back of *Time*, emblematis'd as before; shewing the nature of *History*, which is the immediate representation of things past; and by another *Figure* reviewing the *Sun*, *Moon*, *Stars*, &c. and surrounded with several *Beasts*, *Birds*, &c. denoting the generality of things treated of by *History*.

No VACUUM, Part 1. *Chap. 1, 2, 3. fol. 1.* The *Author* having proved it in his *Book*, 'tis thus represented by the *Sculpture*, a *Boy* pouring *Liquor* out of one *Vessel* into another, thereby shewing, that as the *Air* which occupied the lower *Vessel* is drove out by the heavier *Element* of *Water*, it immediately enters into, and fills the upper *Vessel*; as also by the blowing up of a *Mine*, the visible effects of the extension and dilatation of *Air*: The *Figures* seeming to discourse, represents *Philosophers*.

SMELLING, Part 2. *Chap. 6. fol. 35.* Represented by a *Blood-hound* in scent after his *Game*; by a *Woman* smelling to a *Nosegay*; by a *Man* who seems offended at some unpleasing smell; and by a *Woman* in a swoon, supported by two others, and one of them holding a *Box* or *Glass* of some *Scent* to her *Nose*, which seems to recover her: In prospect a *Pack* of *Hounds* in chase of a *Fox*.

SOUND, Part 2. *Chap. 7. fol. 38.* Represented by several *Musical Instruments* lying on the fore-ground; also by a *Man* ringing a *Bell*, by another sounding a *Trumpet*, by another beating a *Kettle-Drum*, and by a *Woman* tinkling on a *Brass Vessel* to a swarm of *Bees* to hive them, all proper emblems of *Sound*.

OCCULT QUALITIES, Part 2. *Chap. 10. fol. 50.* Represented by a *Man*, seemingly trembling at the sight of a *Lion*, and hastily running from it; by the terror of a *Sheep* at the sight of a *Wolf*; by the seeming trembling and fear of a *Hen* and *Chickens* at the sight of a *Kite*, and by the hasty flight of a *Dove* from a *Hawk*; all the visible effects of qualities proceeding from a Cause admired, but never known.

The BEGINNING or INFANCY of the WORLD, Part 3. *Chap. 1. fol. 54.* Represented by the *Figures* of a *Savage Man*, *Woman* and *Children*, who seem to live in those *Huts* placed in the *Woods*, having several *Animals* about them. The *Primitive Times* supposed to want the conveniencies of *Houses* and *Apparel*, through want of experience.

The SUN, Part 3. *Chap. 6. fol. 62.* Represented by *Phœbus*, sitting in his *Charriot* in the *Clouds*, drawn by four white *Horses*, for the reasons before given in the description of the *Sun* in *Glory*. The *Figures* on the lower part are representations of several *Men*, *Women* and *Animals*, bathing themselves (as it were) in those brilliant Rays proceeding from this warm *Deity*, *Phœbus*, and may teach us how pleasant and joyful it is to live in the *Sunshine* of *Heaven*.

The MOON, Part 3. *Chap. 8. fol. 67.* Represented by the Goddess *Diana*, the having a *Sovereignty* of this seeming *Ball of Fire*, given her by the *Poets*: At her Back are *Dogs* pursuing a *Stag*, the emblem of *Hunting*, of which she is, by the same Authority, Goddess; and underneath is a *Landscape* with *Deer* therein, the *Victims* offered up to her *Divine Recreation*.

The PLANETS, Part 3. *Chap. 9. fol. 70.* Represented by the *Personal Figures* of those *Heaven Deities* from whom they borrow their *Names*. As *Luna*, *Mercury*, *Venus*, *Apollo*, *Mars*, *Jupiter*, and *Saturn*. The reason for these *Gods* and *Goddesses* being so adorned, are given in the explanation of the *Sculpture*, representing the motion of the *Planets*: The *Child* in *Saturn's* Arms, and which he seems to devour, relates to the *Story* fathered on him by the *Poets*, that as soon as ever his *Cœlestial Spouse* was brought to Bed, he did eat the *Children*, to prevent their dethroning him of his *Kindom*.

The GLOBE and SPHERE of the Earth and Heavens, Part 4. *Chap. 1. fol. 81.* Represented by the *Personal Figures* of those two great *Geographers*, *Ptolemy* and *Copernicus*, the one with a pair of *Compasses*, taking seemingly the distances of some places, delineated on the *Globe* of the *Earth*; and the other holding a *Sea Chart*, having a pair of *Compasses*, and the *Sphere* of the *Heavens* before him: The *Figure* seeming as it were to take an *Observation*, represents the *Learned Tycho*; on the *Table* are *Charts*, &c.

FOUNTAINS and RIVERS, Part 4. *Chap. 4. fol. 88.* Represented by the *Figure* of *Thame*, being an *Old Man* lying in the *Reeds* or *Osiers*, having an *Oar* in his Right Hand, and leaning his Left Arm on a *Water-Pot*; as also by the *Figure* *Isis*, being a *Woman* sitting on a *Rock*, having also a *Water-Pot*. *Thame* and *Isis* are storied to be *Man* and *Wife*, and stand as *Godfather* and *Godmother* to that most ample River, vulgarly, *Thames*, it bearing the name of both, as *Thamesis*; as also by the *Figure* of a *Nymph* of the *Rivers* and *Fountains*, named *Arethusa*, holding a *Water-Pot* and *Flowers*; and by the *Figure* of a *Young Man* named *Alpheus*, having a *Water-Pot* and *Cornucopia* of *Flowers*, being the *Patron* of *Fountains*. The *Figures* are thus coupled, to shew that the *Friendly Communication* between *Rivers* and *Fountains*, resemble that between *Man* and *Woman*: The *Figure* in the *Sky*, and seeming to press the *Clouds*, is the emblem of *Rain*.

The SEA, Part 4. *Chap. 5. fol. 90.* Represented by *Neptune*, *God* of the *Sea*, drawn in his *Charriot* by *Sea-Horses*, having his *Trident* in his Hand, being his *wartry Scepter*, the *Hooks* at the ends of it, are to lay hold on his subject *Fishes*, who fail in their *Allegiance*: Behind him are the two *Figures*, holding and seeming to sound through their *Sea-Shells*, are representations of *Tritons*, *Creatures* formed by the *Poets* to serve his floating *Divinity* in the nature of *Trumpeters*. In prospect the *Sea* with *Ships*, &c.

The FIRE, Part 4. *Chap. 7. fol. 99.* Represented by *Vulcan's* *Cave*, in which the *Cyclops* (the *Journey-men Blacksmiths* of *Vulcan*) are at work, in making *Thunderbolts* for *Jupiter*, who is placed above in the *Clouds*,

An Explanation of the Sculptures.

Clouds, attended as usually with his *Eagle*, as inspecting the well-making of his *Weapons*; and behind the *Anvil* stands a *Forge of Fire*, with a *Figure* seeming to blow it, which causes that *Smoke* that arises from the *Funnel* placed by *Jupiter*; below the *Cyclops* Feet lie *Breast-plates*, *Helmets*, &c. in some measure emblems of *Fire*, as owning their form and make, to his *Power*.

EARTHQUAKES and SUBTERRANEAN FIRES, Part 4. Chap. 8. fol. 103. Represented by the *Figures* of the four windy Gods, *Boreas*, *Eolus*, *Auster* and *Zepherus*, each with utmost strength blowing into a *Cavity* of the *Earth*, and heaving up of the *Rocks*, which in several places seem to break forth, and thereby throw down *Trees* and *Buildings*: At a distance the *Figures* of *Men*, *Women* and *Children* affrighted, and running to avoid being buried in *Graves* of *Nature*, making the *Mountain*, whose top breaths flames of *Fire*, represent *Mount Etna*; these *Convulsions* of *Nature* are thus properly emblematis'd, it being the general Opinion that they are caus'd by *Winds*, being inclosed in some cavities of the *Earth*, who are forced to break the surface to find a passage to their proper center.

The AIR, Part 4. Chap. 11. fol. 108. Represented by *Juno* the Monarchess of this Element, with all her *Poetical Equipage* about her, and attended by her four *Handmaids*, *Iris*, *Imber*, *Cometa* and *Rugida*, who all have their *Aerial Employments* under her; as 1st. *Iris* takes care of putting out and taking in the *Rainbow*. 2dly. *Imber* disposeth the *Rain*. 3thly. *Cometa* placeth the *Comets*. And 4thly. *Rugida* distributeth the *Dew*; all which employments are express'd by the emblems that each of them bear.

METALS, Part 5. Chap. 1. fol. 113. Represented by the 7. *Deities*, who according to the *Poets*, patronise the 7. *Metals*; and they are placed in the *Clouds*: That in the midst is *Apollo*, or the *Sun*, holding in his right Hand a wedge of *Gold*, being the *Metal* he is said to produce; on his right Hand sits *Luna*, having a wedge of *Silver* in her Hand, being the *Metal* that owes its being to her proper bounty; that on the left is *Mercury*, arm'd and crown'd; he is said to produce *Quicksilver* by his celeritous Divinity: The four others that appear behind, are likewise said to produce the four other *Metals*; as *Mars*, *Iron*; *Jupiter*, *Venus* and *Saturn*, *Brass*, *Lead* and *Copper*: In the lower part on the ground, are *Directors* and *Diggers* of *Metals*.

The LOADSTONE, Part 5. Chap. 10. fol. 135. Its *Virtues* and *Properties* are demonstrated by the three *Figures* representing three *Philosophers*, one of whom holds a *Knife*, with a *Needle* on the edge; another having the *Compass* before him, and the other holding a *Loadstone* at a distance: The *Figures* of two other *Philosophers* seemingly discoursing of the magnetick power of this wonderful Stone.

The WINDS, Part 6. Chap. 2. fol. 136. In the *Sculpture*, *Apollo* sitting in the *Clouds*, and pointing to the God of the *Winds*, *Eolus*, who sits in the *Clouds* below him, adorned as before, commanding the four *Winds* express'd by the four *Figures* of *Boreas*, *Zepherus*, *Eolus* and *Auster*, with their proper emblems as before, to discharge their Office; their execution of his Commands are visible in the effects of the *Wind* upon the seemingly tost and overwhelm'd *Ships* in the *Sea* below.

The NYMPHS of the Air, emblems of *Clouds*, *Mist*, *Snow*, *Hail*, *Rain*, *Dew*, &c. Part 6. Chap. 3, 4, 5, 6. fol. 139. 1st. Represented by two *Nymphs* of the *Air* in their proper array, young, beautiful and winged, stretching out their *Arms*, as gathering together and dilating the *Mists*. 2ly. The *Nymph Nix*, scattering of *Snow* through a *Sieve*. 3dly. The *Nymph Imber*, pressing the *Clouds* to provide *Rain*. 4thly. The *Figure* of a *Man* scattering small *Hail* out of a *Water-Pot*; and underneath three *Figures*, the middlemost representing *Dew*, the 2d. *Snow*, and the 3d. small *Hail*. In prospect a *Landscape* covered with a cast of each of their Offices to which they are assigned by the *Poets*, and therefore may properly be used in *Sculpture*, it being an attendant of *Painting*, which is *Poema silens*.

STORMS and THUNDER, Part 6. Chap. 7. fol. 147. *Thunder* is represented by *Jupiter*, preparing to cast his noisic *Bolts*: and the *Storms* by *Eolus*, the God of the *Winds*, commanding the four *Heads* who breath out *Storms* in their *Stations*, as *Boreas* in the *North*, *Zepherus* in the *West*, *Auster* in the *South*, and *Eolus* in the *East*: Below is the true emblem of a *Storm*, being *Ships* tost in a rugged *Mountainous Sea*; the *Fires* seeming to blaze on the *Main Yards* of the *Ship* are two *Sea Wills* in the *Wisp*, and made by the *Poets*, tho' not *Gods*, yet *Godlings* of the *Sea*, and *Protectors* of *Seafaring-Men*, and by them named *Castor* and *Pollux*, the names of two *Brothers*, reported to have been drown'd.

The RAINBOW, Part 6. Chap. 9. fol. 151. A *Rainbow* proper, surmounted by *Iris* the Goddess thereof, the *Rays* of the *Sun* darting on it; by which, as we conjecture, it receives those beautiful and various *Colours*: The *Figures* below, represent *Philosophers* as con-

sulting concerning its *Nature*; and about that *Ignis-Fatuus* which appears in the *Fields* of the *Landships*; the representation of a *Nymph* or beautiful *Virgin*, placed on the *Rainbow*, took its rise from *Jove*, but since hath been attested for reality by a *Captain* of a *Ship*, who solemnly asserts his having seen it so.

GARDNING, Part 7. Chap. 1. fol. 156. In the *Sculpture*, the 1st. *Figure* is the Goddess *Rea*, *Commandress* of the *Earth*, seated thereon, as her proper *Throne*, having a *Castle* on her *Head*, and a *Lion* by her *Side*, emblems of her *Strength* and *Power*; next her is *Hebe*, one of *Jupiters* *Cup-bearers*, pouring out *Wine* on the *Earth*, as the *Typh* due to her producing it; the next *Voluntina*, who assists the *Flower* in budding; then *Flora*, embracing the *Plantain-Tree*, being consecrated to her, and holding in her *Hand* a *Flower*, being Goddess thereof; behind *Rea* is *Virtumnus*, holding one *Fruit*, and eating another; on the left side of the *Tree* is *Nodinus*, holding the *Leaves* as it buds into *Branthes*: Next is *Proserpina*, who hath the care of the *Bud* till it is out of the *Earth*; behind *Nodinus* is *Patelena*, holding a *Leaf* in its full perfection: The reason for this representing *Gardning*, arises from the authority of the *Poets*, who have made all these *Gods* and *Goddesses* concerned in the preservation of those *Vegteables* that adorn it, tho' I suppose they only meant the *Garden* of the *Muses*, in which none but they and their *Successors* were to be allowed the liberty of walking: In the upper part of the *Sculpture*, are the representations of *Jupiter*, *Juno*, *Saturn*, *Feronia* and *Luna*, in their proper emblems, relating to their several *Empires*, as before discours'd of, and intimates the necessity of the good will of *Heaven*, and temperate seasonable *Weather* to bring the *Fruits* of the *Earth* to perfection.

NATURE of ANIMALS, Part 8. Chap. 1. fol. 175. For *Animals* begot, they are represented by a *Woman* suckling her *Child*, having a *Cradle* standing by her; their *Thirst* represented by a *Cow* a drinking; their *Hunger* by a *Deer* grazing, their *Action* by two little *Dogs* a playing, their *Sleep* by a *Cat* a sleeping; their *Wakefulness* by a *Cock* sitting on his *Pearch*, and seeming a *Crowing*; their *Sickness* by a *Farrier* bleeding of a *Horse*, and their *Death* by a *Horse* lying dead.

IMAGINATION, Part 9. Chap. 6. fol. 214. Represented by a *Woman* in a seditary posture, having on her *Head* a pair of *Wings*, and a *Coronet* composed of small *Figures*, which *Figures* denote the productive faculty of *Imagination*, and the *Wings* its swiftness: The *Child* standing by the *Figure* of *Imagination*, partly black partly white, denotes the strength of this *Passion*, being able (as by this Example appears) to perform those things, which neither *Human Wisdom*, nor the common way of *Natures working* could effect: The other *Figure* having *Eyes* veiled, and *Wings* on her *Back*, represents what *Women* call *longing*; 'tis swift as *Wings* to *Desire*, and blinded to *Reason*.

MEMORY, Part 9. Chap. 7. fol. 216. Represented by a *Woman*, having a *Steel Cap* on her *Head*, set with *Jewels*, denoting the *Strength* and *Riches* of this *Faculty*; she is putting her *Finger* to her *Ear*, as the proper *Organ* by which this *Good* is received; and in her *Hand* she holds the *Picture* of a *Man*, whom she knows, tho' absent, by the means of *Memory*; below are the representation of *Children* conning their *Lessons*, and of a *School-Mistress*, who seems awing them with a *Rod*; The *Statue* on *Horseback* is the representation of *King Charles II.* as the properest object to exercise this *Noble Faculty* of *Memory* upon.

The *Author* having asserted in his *Discourse* of the want of *Sense* and *Knowledge* in *Brute Animals*, that they are nothing more than *Machins*, moving in their several *Stations* by *Natures Clockwork*: His ingenious position is illustrated by the *Sculpture* that fronts the said *Tract*. First on the foreground is the *Figure* of a *Woman*, being the representation of *Dedalus* his *Wooden Venus*, which imitated the *Action* of a *Woman*; next in the midst the *Figure* of a *Man*, being that *Iron Statue*, which presented a *Petition* to the *Emperor of Morocco*, as taken notice of in the latter end of that *Authors Preface* to the *Reader*. On the *Right Side* of this *Figure*, is that of a *Man* with a *Drum*, which artificially beats on it, and at the same time performs several motions with his *Head* and *Eyes*; which *Clockwork* was shewn in *London* not long since. Between these aforesaid three *Figures*, is a *Dial* and a *Dog* sitting, which is another piece of *Clockwork*. At a distance on the second ground, is supposed the *Army* of *Maximilian* the *Emperour*, over whose *Head* is an *Eagle*, being the representation of the *Norimberg Eagle*, framed by *Athanasius Kirckir*, which flew over his *Head*, and accompanied him in his return to the *City*. Then on a *Hill*, a *Statue* of a *Man*, which saluted the *Sun* at his rising, with a *Hymn Musically* composed: And to conclude, a *Pidgeon* framed by *Architus* the *Tarentin*, which flew in the *Air* like a living *Bird*; all which the *Author* hath taken notice of, to which I refer the *Reader*.

THE PREFACE.

SECTION I.

Of the Nature, Principles, Object, Use, Rise and Progress of PHILOSOPHY.

PHILOSOPHY, according to its Etymology, is the love and study of Wisdom; where by Wisdom we understand such a disposition of the Mind, by which Man is firmly inclined to have right Sentiments of the Things that occur to his perception, and to make a just Examination of the Actions that belong to his Life. For Wisdom doth not only direct the Understanding, and guide the Mind in the Contemplation of Truth; but also inclines it to Honesty, and assists the Will in the prosecution of Vertue: So that Wisdom is indeed nothing else but a perfect Knowledge of all those things which it is possible for Man to know, and which may be both a Rule to his Life, and a Help to the Inventing of all Arts whatsoever.

What PHILOSOPHY is.

Whence PHILOSOPHY may be defined a Habit of the Mind, acquired by Study and Exercise from Inborn Ideas and self-evident Principles, enlightning the Understanding into the knowledge of necessary things, and perfecting the Will by Honest and Vertuous Actions.

How it is defined.

Now to the end this Science may have these Effects, it is necessary that it be deduced from first Causes; so that whosoever desires to be Master of it, must begin with an enquiry into these Causes: Because this is the first property of the Principles of Things, to be so clear and evident as not to stand in need of any proof of their Certainty, and to be raised beyond the reach of Doubting; so that whosoever minds them, can't doubt of their Truth. Secondly, They are such on which other things depend, and without the knowledge whereof nothing of Certainty can be had. Wherefore tho' the first Causes of Things may be known, tho' the Things themselves be unknown; yet it is impossible, but that when these are known, those must be likewise known; because the Truth of these depends on the evidence of their first Causes. And accordingly whatsoever is demonstrated concerning them, without a self-evident Principle must needs be dark and uncertain. For as DESCARTES saith; No Conclusions deduced from an unevident Principle, can be evident, tho' they should be deduced thence with the greatest Evidence imaginable.

Of what kind the Principles of Philosophy are to be.

It is not only one Genus, or general Head of things, that is the Object of PHILOSOPHY; but she extends her self to all things which the Mind of Man is capable of knowing. And therefore Plato, as Ammonius tells us, called it The knowledge of things Human and Divine; forasmuch as it doth not only consider Corporeal Things, but also contemplates the Supream Cause and Intelligences void of Matter, and enquires into their Attributes and Perfections. For this is it (saith Cicero) which dispels all dimness from the Eye of the Soul, and enableth us to see all things, whether Superior or Inferior, first, last, or middlemost.

What is the Object of Philosophy.

From whence we may gather the true Use of PHILOSOPHY, and how many Advantages it affords us. For, first it helps the Soul to contemn those Transitory and Temporal things, to which from its Childhood it has been too much addicted, and raises its desires to things Heavenly and Eternal. Secondly, It assists us in the thorough search into our own Natures, in the knowledge of our Creator, and the attentive Consideration of his Works. Thirdly, Whilst it evidenceth Truth to us by clear and indubitable Demonstrations, it affords us extraordinary pleasure and delight, as displaying those things in a full light to us, which are hid from the greatest part of Mankind. Fourthly, It removes Wonder, which ever is the Companion of Ignorance, and gives us a clear Light, whereby to discern Great things from Small, and to esteem things according to their true Value. Fifthly, By the Exercise hereof we are prepared to know the several Objects we meet with more distinctly, and to judge of them with more Caution and Exactness; for by the long continued Study of Philosophy we become more prudent and cautious in passing Sentence concerning things.

What is the Use of Philosophy.

The P R E F A C E.

Whence Philo-
sophy had its
rise.

PYTHAGORAS was the first amongst the Ancients who assumed the Name of Philosopher, by way of Modesty, as condemning the Pride and Arrogance of others who would be called Sophi, that is, Wise Men. For this discreet Person was so sensible of our Ignorance, that he thought that that Title did beseeem God alone, and could not deservedly be given to any Mortal. But because the Original of Wisdom and Philosophy is one and the same, which was many Ages before Pythagoras, we must look for it long before his time: Which if we do, we shall find that it could not proceed from any one else but God, the Father of Lights, from whom every perfect Good comes, and the Truth of all things is derived. Hence it is the Poets tell us, That Pallas or Minerva, the Goddess of Wisdom, was the birth of Jupiter's Brain; intimating thereby that all Knowledge comes from GOD, and takes its rise from his Understanding. For it is certain that Adam, the first of Mankind, was a wise Man, forasmuch as he gave Names to Things, and taught his Sons the knowledge of the Stars, which he could never have done, if he had not been endued with Wisdom, and understood the Nature and Property of Things.

How Philoso-
phy has been
transmitted to
us from Adam.

It is probable that this most excellent Gift of God, was handed from Adam by Methusalem to Noah, and from him, his Sons and Grandchildren, to the Chaldeans and Hebrews, who were famous for their Knowledge of many things, and from them to the Egyptians; from the Egyptians to the Grecians, and from them to the Romans; from whom, in process of time, the same was derived to the Northern and Western Nations.

How some
think it had
its rise accord-
ing to the Na-
ture or scitua-
tion of Coun-
tries.

Some that begin not the Pedigree of **PHILOSOPHY** so high as we do, tell us, That it had its rise according to the Nature or Scituation of the Countries where those lived who had the first Knowledge of it: Necessity, which is usually the first Mistress of Sciences, having taught them what were proper for their Needs. 'Twas thus, say they, that the **EGYPTIANS** began to observe the Increase and Decrease of the Nile, and to make every Year a Prognostick of the Fruitfulness or Sterility of their Lands. And to part, with the more facility their Harvest, among those parti- cular Persons who were to have their Shares thereof, they learnt the first Principles of Geometry. The **ASSYRIANS**, who inhabited vast and unclouded Countries, having nothing to hinder them from contemplating the Stars, were the first that observed their Motion; and the **CHAL- DEANS**, who were amongst these People a kind of Philosophers, found from this Speculation an Art of Foretelling things to come. In fine, The **PHÆNICIANS**, who were Neighbours to the Sea, drew another Benefit from the Knowledge of the Stars, and addicted themselves to observe those which might be useful to Navigation; in which they succeeded so well, that they found out that there was a fixed Point towards the Pole, the observation of which might be a Guide to Pilots.

S E C T I O N II.

The Chief and most Celebrated PHILOSOPHERS.

THALES.

Amongst those who are most Celebrated for Philosophy, **THALES** the Milesian, so called from Miletus the Capital City of Ionia, in which 'tis said he was born, 639 years before Christ, is accounted the first. He was a great Astronomer, and the first that observed the Solstices and Equinoxes. His Opinion was, That Water was the Principle of all Things.

**ANAXIMAN-
DER.**

The Successor of Thales was **ANAXIMANDER**, who was also Born at Miletus, and the first Founder of the Ionick Sect. He distinguished the Four Elements, placed the Earth in the Center, and by the scituation he gave them, was the first that erected a kind of System of the World. Strabo and Laertius assure us, that he was the first also that made Maps. He never determined, as Thales, which of the Elements was the Principle of Natural things, but concluded it to be Immenſe.

**ANAXIMI-
NES.**

ANAXIMINES followed Anaximander, being also Born in the same City. He owned Infinite Air to be the Principle of all Things. His Disciple was **ANAXAGORAS** of Clazo-

**ANAXAGO-
RAS.**

mene, who was the first that brought Philosophy from Ionia to Athens. He declared Matter and

ARCHELAUS.

Spirit to be the first Principles; that at the Beginning all Things were in Confusion, and that it

HERACLITUS

was the Spirit that separated, distinguished and establish'd them in that beautiful Order wherein we see them. Anaxagoras his Scholar was **ARCHELAUS** the Athenian, who was the Asserter of

DEMOCRITUS

Similar Parts, and held Heat and Cold to be the Principles of all Things. To these also may be added, **HERACLITUS** the Athenian, who maintained that the first Principle was Fire: And **DEMOCRITUS** the Abderite, who would have it to be Atoms. These were of the Ionick Sect.

**PYTHAGO-
RAS.**

PYTHAGORAS of Samos, flourished in the Year 571 before Christ, and was the first that Instituted the Italick Sect in that part of Italy commonly called Great Greece, now Calabria. He took a different course from his Predecessors, vailing his Natural and Divine Philosophy under the

The PREFACE.

the secret Science of Numbers, and was full of Symbolical and Figurative Expressions, being persuaded that it was to profane the Truth, to expose it naked to the Eyes of the People. His Disciples were not permitted to speak of the Mysteries he taught them, till after five Years continual Silence. It was his Fundamental Maxim, that Unity was the Principle of the Generation of all Things, and that Plurality was the Corruption of them. To these Numbers he added a certain Harmony, by which he explained the Perfection of all Things. Vertue (according to him) Health, the Soul, and God himself is nothing but an Harmony, and there is nothing more known than the Harmony which this Philosopher imagin'd to Rule the Celestial Orbs. He held the Transmigration of Souls, discovered the Qualities of each Element, the figure of their Bodies, the roundness of the Earth, and the Antipodes. He distinguished the Seasons, observed the different Course the Sun makes daily and yearly, and how the Moon receives her Light from it.

SOCRATES, who was Born at Athens 468 years before Christ, leaving the Study of SOCRATES. Natural Philosophy, wholly addicted himself to Ethicks. Accordingly Tully, in the Third Book of his Tusculan Questions, tells us, That all that Philosophy which undertakes the Conduct of Life and Manners, was derived from Socrates; and therefore saith, That he had called down Philosophy from Heaven, to take up its abode in Cities and Houses.

PLATO, an Athenian, was born in the year 427 before Christ, and for his extraordinary Learning and wonderful Sagacity in the searching out of Truth, had the Name of the Divine Philosopher bestowed upon him. His School set about with Trees was in the Suburbs of Athens, first called Ecademia, from one Ecademus the Possessor of it, and afterwards Academia, which gave the Name to his Sect. He concluded God, Idea and Matter, to be the Principles of all Things. Concerning his Opinion of these Idea's, the Learned are much divided. Some would have him hold that they are Eternal Substances, Forms existing from themselves, and distinct from the Knowledge of God, as Models quite separated from him, and such as upon which he forms the Ground of his Work. But others are of another Judgment, declaring that in his Doctrin the Idea of the World is no other thing than the Image the Creator has formed. As for Matter, he suppos'd it to be void of all Form, and that before the Creation of the World it was a kind of Chaos, yet capable of all Forms; And forasmuch as it hath a Disposition whereby it may be distinguished into divers Bodies, which disposition he makes to be nothing else than a Pyramidal, Cubical, or other kind of Figuration, of the least and invisible Particles of which the Elements are compounded; He consequently asserts, that Pyramidal volatile Particles constitute Fire; that Cubical and sub-fiding Particles make Earth; Octahedrical or Eight corner'd, Air; and Eicosahedrical or Twenty corner'd, Water.

ARISTOTLE, the Son of Nichomachus, Born at Stagyræ in Macedonia 383 years before ARISTOTLE. the Birth of Christ, differed much in his Sentiments of Philosophy from his Master Plato, who therefore compared him to a Colt kicking his own Dam. He had the Liceum for his School, a House near Athens, which had been Apollo's Temple, built by a certain one called Licus. Here his Disciples Disputed Walking, from whence that place, according to the Greek word for it, was called **PIRAPATVS**, and they themselves **PERIPATETICKS**. This Philosopher became Famous by being the Præceptor of Alexander the Great, as well as by his sharp Wit, and the great number of his Writings. He held Matter, Form and Privation to be the Principles of all Natural Beings.

ARCESILAUS of Sardis in Lydia, flourish'd in the Year 297 before Christ, and Taught at ARCESILAUS. Athens, where he was the Author of a Sect called in after Times the Middle Academy, to distinguish it from the Old Academy, which begun with Plato; and from the New, which was instituted by Lacides of Cyrene, as will be presently declared. He asserted that there was no Certainty, but only a bare Probability in the Knowledge of Things; so that he thought we might equally hold Pro and Con upon all Subjects, and therefore would never determine, but always suspended his Judgment.

LACIDES the Cyrenean, newly mention'd, Taught in the same School some years after LACIDES. Arcesilaus, and was the Head (as I said) of the Sect which was called the New Academy. He acknowledged that something was highly probable, at least that one thing was more probable than another, and accordingly determin'd; but was not sure that any thing was absolutely True.

PYRRHO of Elæa, was also the Founder of a New Sect, that is, a New manner of Philo- PYRRHO. sophizing; for he had no Dogma's at all, as believing that nothing was true or likely, that is, so much as probable. He went beyond the Academicians: For whereas they comprehended, that Nothing could be comprehended, he did not comprehend that. His Followers were called **EPHECTICI**, from their withholding their Assents: **SCEPTICI**, from their Considering and Canvassing: **ZETETICI**, or Seekers, from their Search and Enquiry: And **APOZETICI**, from the continual Doubts and Difficulties they were used to object to the Dogmatical Philosophers.

The P R E F A C E.

Z E N O.

Z E N O the Citian had his School at Athens in a Painted Gallery called Stoa, whence his Disciples had the name of Stoicks. Vertue was the Sovereign Good in his Morals, and he is famous for that Constancy he inspired into his Followers in the extremity of Affairs. They would never confess Pain to be an Evil. He held the first Matter to be destitute of all Qualities, as of Heat, Cold, &c. as also without any Form, Shape, or Figure. He supposed that besides the World, there was a certain infinite Space altogether void and empty, in which the World after its Conflagration might be resolved. He asserted two Principles, viz. God and Matter, without which nothing could subsist.

E P I C U R U S.

E P I C U R U S was Born at Athens 257 years before Christ. He kept his School in some Gardens in that City, and was the Author of a peculiar Sect. He Taught, as well as Z E N O, the love of Vertue; but that only for the Pleasure of it, and in that Pleasure he comprehends that of Sense, as well as that of the Soul; maintaining, That a Wise Man could not be happy, if he enjoyed not all Pleasures Mankind was capable of. In this he did not so well explain himself, but that he gave occasion of raising Doubts concerning his true Conceptions; some believing them to be Innocent, whilst others, and those the most numerous, think otherwise; inso-much that the Epicureans are now generally look'd upon as too Sensual. The rest of his Morals, concerning God, Providence, and the Soul, are also much blamed. He took from D E M O - C R I T U S the Principle of his Physick, adding thereto the declension of Atoms, with a motion of Weight. His Opinions were, That nothing was without Beginning or End, but Atoms and empty Space: That the Universe always abides unchangeable in the Whole, tho' as to its Parts it be variously altered. He endeavours to prove the necessity of an Empty Space from Motion, and asserts, that the World shall some time or other be dissolved by the force of Nature.

G A S S E N D U S.

The Famous P E T R U S G A S S E N D U S, Mathematick Professor in the University of Paris, Born in Anno 1592, hath endeavoured to Amend and Perfect the Epicurean Philosophy, especially by refuting its Errors concerning God, Providence, the Souls Immortality, &c. and by a cautious Explication of such of his Opinions in Natural Philosophy, which tho' not utterly condemned, yet not being sufficiently proved, but Doubtful and Slippery, might be an occasion of falling into Error.

D E S C A R T E S.

After all these was Born R E N A T U S D E S C A R T E S, at la Haye in France, of a Noble and Ancient Family, in the year of our Lord 1597, who by a Method, before his Time but imperfectly known, restored Philosophy from the very Foundations, opening a sure and solid Way to Mankind into the inmost Recesses of Nature. He was of such a singular Genius, that he alone discovered more Philosophical Truths, than ever were discovered in all foregoing Ages. We do not go about here to give any Instances of his Philosophical Sentiments, since this whole Work contains nothing else, but his Opinions, or what may clearly and distinctly be deduced from them.

S E C T I O N III.

The Parts of P H I L O S O P H Y, and the Design of this whole Work.

Of the Parts
of P H I L O -
S O P H Y.

P H I L O S O P H Y is commonly divided into Three Parts, viz. First, Into M E T A P H Y - S I C K S, or N A T U R A L T H E O L O G Y, which proves the Being of a God, or First Cause, on whose existence all Truths depend, and without the knowledge of whom no Science can be had. Secondly, Into P H Y S I O L O G Y, or N A T U R A L P H I L O S O P H Y, which comprehends the Principles of Material Things, considers the Original of the World, and enquires into the Parts whereof it doth consist; and afterwards descends to consider the Form, and Qualifications of the Sun, Stars and Planets; the force and vertue of the Air, Water, Fire, Fossils, or things dug out of the Earth, as Metals, &c. And lastly, Enquires into the Nature of Plants and Animals, and more especially of Man, who is a Compendium of the Universe; and lastly into M O R A L P H I L O S O P H Y, or E T H I C K S, which searches into the Nature of Good; discovers what Manners are honest and becoming, and directs and governs all our voluntary Actions, according to the Rule of Right Reason. But to the end that in the handling of Philosophy the Modus (that is, the Natural Way and Order) of Science may be observed, I have rather thought fit to distinguish Philosophy into Ten Parts, that by this Division my Discourse might be more Methodical, and avoid the Confusion which is incident to the former Partition.

LOGICK,
the First Part
of Philosophy.

I thought fit therefore to make LOGICK the First Part of my Discourse, it being the Organ or Instrument of all P H I L O S O P H Y, and very necessary to the attaining of all Sciences. Because I never esteemed any thing more valuable in Man, than a good Mind or

Under-

The P R E F A C E.

Understanding, whereby he is enabled to unfold the Natures of Things, and to discern Truth from Fallhood. For all other Gifts of the Mind have their Bounds, and are only determin'd to some particular Offices: But the Rectitude of the Understanding is conducive to all the Uses of Life; and is not only profitable in the dispatch of Business, but for the attaining of Arts and Sciences. For this Reason it is that I have begun this Philosophical Treatise with LOGICK, which is the Art that Teaches the right use of Reason, and how Man ought to manage his Thoughts in the knowing and judging of Things. And forasmuch as the Mind of Man is subject to many Errors, and is biast for those Opinions it has embrac'd during Childhood, having premised something of the Usefulness of LOGICK, I take occasion to advise every one carefully to avoid the Prejudices of Infancy, and not to admit any thing for Truth, but what clear and distinct Perception hath manifested to be such. For he judgeth wrong who doth not give heed to his Conceptions, and compriseth more in the Conclusion, than he had perceived in the Premisses.

For the avoiding of this Præcipitancy, I first examin the simple Terms of Things, and briefly enumerate those Notions of which our Thoughts are compounded; afterwards I set down a Scheme of Substance, and its Attributes, by which it is more distinctly understood and distinguish'd from the Modes that belong to it. To this end it will be of great use attentively to consider the Genealogy of Things and Modes; as also the Imposition, Signification, Definition and Use of Names. But because it is not sufficient to have Idea's of Things, except we know also whether they be simple, or resolvable into other Parts: I have added the Chapter of Definition and Division, by which means all Confusion may be removed, and the Nature of every thing, and its distinction from others more clearly known.

After the clear Perception of Things, I come to the Judgment we are to make of every Thing; and in so doing, I proceed from simple Things to those that are Compound, and as it were from the first Step of Logick to the second. The Sum whereof is this, That in our search of Truth, we never give our Assent to any thing which doth not exactly answer to our Perception: For it is not enough that Truth be in this or the other thing, except the same do appear to us, and we be fully convinc'd of its Certainty. For I take him to know nothing at all, who relies only upon the Authority of others, and is led by their Judgment, without hearkning to his own.

After this, I proceed to the Explication of a Syllogism, which is made up of divers Judgments that are found of them. Now whether Syllogisms are of so great use towards the acquiring of Sciences, as in the Schools they are boasted to be, I dare not assert, seeing that the greatest part of those Errors Men fall into are much more caused by their using of false Principles, than by their not observing the Rules of Good Reasoning. However, they must be acknowledged to have their Use, as being very helpful for the exercise of Wit, and more especially for those, who through overmuch Subtilty, or want of due Attention, suffer themselves to be deceived by false Consequences, and to be led into Error.

That which concludes this Part of PHILOSOPHY, is METHOD, which is the chiefest Part of Logick, and without all Controversie the most useful. For it being that Judgment of the Mind, by means of which whatsoever belongs to a whole Science is fitly and rightly disposed and digested; it is extremely conducive to the discovering any Truths we are ignorant of, or to the convincing of others of those we know already. This Method in particular is either Genetical or Analytical, in both which the true Practice of Logick is perfected.

But forasmuch as all our Knowledge is uncertain, as long as the most perfect Being, from whom all others do proceed, is not known to exist; therefore I begin the Second Part of this Treatise with the Existence of GOD. This I evince from the Idea we have of him which represents a Being absolutely perfect, wise, and powerful. For 'tis a Contradiction, that that which includes all Perfection should not be necessarily Existent, seeing that Existence is a vov'd Perfection, which therefore can't be absent from a Being absolutely Perfect. And therefore as we clearly understand, that in the Idea of a Triangle is contain'd, that its three Angles are equal to two right ones; so we find, that in the Conception of GOD is involved Necessary and Eternal Existence. From hence we duly infer, that GOD is the Creator of all things, not only in respect of their Existence, but also of their Essence: So that even the Propositions of Eternal Truth do depend on this first Truth, and are no farther True than as they are determined thereby. The Existence of GOD being demonstrated à priori, I proceed to lay open his Attributes, which by necessary consequence follow from it; since it is impossible but the supream Being must include Unity, Eternity, Omnipotence, Immenstity, Beneficence, Providence, &c.

Having thus examined the Nature of GOD, and inquired into his Perfections according to the measure of our weak Understanding, the next in order to be considered, are the INTELLIGENCES and DÆMONS, whose Existence, as far as it can be reached by Natural Light, I have endeavour'd to demonstrate: And afterwards proceeding to their Faculties, have shewed

The P R E F A C E.

them to be endowed with Understanding and Will: And because there is no small Dispute betwixt our Divines and the Talmudists, concerning their Number, Distinction and Subordination, I have barely set down their Opinions without adding any thing of my own. Thence I pass to the Power they have to assume Bodies; and add something concerning the Care and Concern they have for Mankind, which I briefly confirm from Texts of Scripture and Reasons deduced from their Natures.

The Fourth
Part; Of
Natural Phi-
losophy in
general.

It being proved that there is a G O D, by whose Power the Angels and all Things are produc'd, and that it is repugnant to his Nature to deceive us: We are sure that we can't be mistaken in those things which are clearly and distinctly known by us; and therefore seeing we have clear and distinct Idea's of Bodily Things, which we are not the Causes of, as being often represented to us, whether we will or no; I thence infer, they must needs proceed from Objects without us, which really and actually exist in the World. For otherwise, if G O D should immediately impress such Idea's on our Minds, or cause them to be convey'd from Objects in which there was nothing of Extension, Motion, or Figure, it would follow that he did impose upon us; and therefore we must conclude, that there is a Substance extended in length, breadth and depth, or thickness, which we call Body, and is the Object of this Fourth Part. For all things that are handled in Physiology belong to Body, as its Forms or Affections.

Let not any one wonder that I exclude all substantial Forms from a Body, or extended Matter, since they are so obscure that they can't be explain'd, no nor so much as conceived by those very Men who are the great Patrons of them. Whereas on the other hand, nothing is more obvious and agreeable to our Senses, than to assign the Effects of Nature to the different Magnitude, Figure, Position, Motion, and the Rest of Bodies. Who is so stupid as not to apprehend these Principles? Is it not better to explain Things by Causes known and obvious to all, than to have recourse to some Principles, which none understand, and which are as dark and difficult to those that teach, as to those that learn them? It is folly to admit any thing in PHILOSOPHY which no Body could ever yet comprehend, no, nor I dare boldly say, ever will be comprehended.

If we admit that Material Substance consists in a Threefold Dimension, and that it can't be distinguished from Extension, save only by Reason or a Mental separation; it will be easie to demonstrate, that it is impossible for any Vacuum to be in Nature: That Rarefaction is only made by the intervening of New Matter: That the World is not circumscribed by any Bounds: That the Internal place of a Body, doth not at all differ from the Body it self; and that the Heavenly Matter is of the very same Nature with the Inferior and Sublunary. Forasmuch as that which the Philosophers call Quantity, is not the precise extension of the Body, but only its extension as such; that is, with respect to its being commensurate to such a number of Inches, Feet, Yards, &c. it being apparent that a Body retaining the self-same quantity, may be further extended in length and less in breadth, or on the contrary. As Matter hath some Essential properties, viz. Divisibility, Figure, Mensurability, and Impenetrability; so likewise it has some common Accidents, viz. Rarefaction, Local Motion, Heaviness, Lightness, Hardness, Softness, &c. which are not in it, as so many distinct things; but only as Modes, which can't be separated from the Body; and if they could, they would be no longer called Modes, but Substances, whose peculiar property it is to exist by themselves, and independent of any Subject. And seeing that as all the diversification of Matter, or the variety of its Forms, depends on Motion, by which the Matter is divided into Sensible and Insensible parts, I clearly make out, that the Three Elements of the World had their rise thence. Then having shewed that a Body hath no power to move it self, I make it appear, that all those Motions, which by the Peripateticks are commonly attributed to the prevention of a Vacuum, are occasioned, because all Motion of Bodies is in a manner circular, one succeeding in the place of another. Then I proceed to the determination of Motion, whether simple or compound, treat of Reflection and Refraction, of the Acting and Resisting power in Bodies, and wherein it consists. Afterwards of the state of Bodies, as to their Hardness, Fluidity, Rarity or Looseness of Parts, Closeness, Roughness and Smoothness, &c. where I shew, that there are Pores as well in fluid, as in hard Bodies; and last of all give a hint, that the Ends of G O D are not to be searched into in Physiology, because it is an Argument of Rashness and Arrogance. And as for TIME, under which we consider the Existence of Created things, it is improperly said to be an Affection belonging to them, since indeed it is a meer Mode of Thinking, serving only to explain Duration, and distinguish the Parts of it.

The Fifth Part;
Of the World
and Heaven.

Having thus laid those Foundations of NATURAL PHILOSOPHY, I proceed to consider the Unity and Perfection of the World, and endeavour first to shew, that the Creation of it may be discovered by Natural Reason: That its Extension is immense, or rather indetermin'd, so as not to be circumscribed by any Figure, or Bounds: That the Matter of Heavenly and Earthly Bodies is one and the same; and enquire at large what is the Form of the World, whether

The P R E F A C E.

whether it be the Soul, that is, the Spirit of Nature, or the best disposition of Parts: And in the next place assert, That GOD hath communicated to the Matter whereof the World is made, a determinate Measure of Motion, and doth preserve the same quantity in the same. Then pass on to examine the Action of Bodies, and the communication of Motion, and add some Rules by which we may know, what must of necessity happen in the meeting of Bodies. Then follow the Three noted Systems of the World, viz. The Ptolomaick, Tychonick, and Copernican, and after having rejected the two former, I with Descartes embrace the latter, as being more simple and better agreeing with the several Phænomena of the World. Then shewing the Heavens to be fluid, I go on to Evidence how they were disposed or rank'd at the beginning, and of what manner their Motions were, and what is the Action of the Heavenly Matter. And for a better understanding of the Celestial Motions, I define the Heavenly Globe with all its Circles, and their several Uses. Then examin the Nature of the Sun, the Adjuncts of Light and Luminosity. How Spots are generated about the Sun and the fix'd Stars, and vanish again. What Comets are, and how it comes to pass that fixed Stars are changed into Comets.

Next to the Comets are the Planets, whose rise is shewed, together with the Principle of their Motion, and how they become Direct, Retrograde, and Stationary. Then the Moons motion is considered, with its various Appearances, and the Eclipses of it, as well as of the Sun. Next follows the Nature of the fix'd Stars, their Number and Constellations, and concerning their Influences, as well as of the other Stars, and what Judgment we are to make of Judicial Astrology.

Having thus taken some Turns in the Heavens, we return again to the Earth, to take a more exact Account of its Original parts and Figure, and the manner of its being moved in the fluid Heaven; demonstrate also its Motion by Reason, and Answer the Objections made against it; and then discover all the Vicissitudes of Night and Day, and the several Seasons of the Year, which proceed from the Diurnal and Annual motion of the Earth. Then take notice of the Five Zones, invented by Geographers, to distinguish the Variety of Heat and Cold in the several Parts of the Earth, occasioned by the nearness or distance of the Sun; and the Climates made use of, for a more distinct Explication of the several Tracts and Regions of the Earth. Then proceed to the discovery of those Things which are generated in the Bowels of the Earth; as Fountains, Metals and Minerals, Stones, Gems, the Load-stone, and Electrical Bodies. After, speak of the Water, the Flux and Reflux of the Sea: Of the Air, and its Elastick virtue. Then of the Meteors in general, and particular; as of Winds, Clouds, Mists, Rain, Dew, Hoar-frost, Cool of the Evening, Snow, Hail, Thunder, Lightning, Coruscations, the Rainbow, Circles formed about Stars, and Mock-Suns. Then unfold the Nature of Fire, Heat and Cold: The most remarkable Effects of Fire, as the Effervescence of some Bodies, and the Turning of others into a Calx or Ashes, Earthquakes, Fermentation, &c. and last of all consider the Mixtion, Generation, Corruption, Alteration, Augmentation, and Diminution of Bodies.

Having thus largely enough handled (as I suppose) Inanimate things, I proceed to those that are Living, and having premised their Distinction from Things without Life, I assert their Life to consist in a due Temperament of Heat and Moisture, and consequently that their Death proceeds from the contrary Causes of Cold and Dryness. Next I enquire into the Cause of the Hardness which is observed in the Outside of them, and of the difference of this Vital Heat in Living Creatures, and why the same is weaker in some, and more strong and durable in others. Then discover the Nature and Virtue of the Aliment or Food wherewith Living Creatures are Nourished, and how Living Things come to be changed by the diversity of Place and Time; and then come down to Plants, and having explained their Parts, Original Nutrition, Growth, Difference and Propagation, I enquire into the Causes of their different Colour, Taste and Smell; as likewise of their Perishing or Death. Lastly, I lay open the Nature of Animals, what the Souls of Beasts are, and then examin in particular the Nature of Fourfooted Beasts, Creeping Things, Birds, Fish and Insects, and wherein the Death of these consists.

After having taken a View of this Great World, I proceed to the Consideration of the Lesser World MAN, who may be defined a Compound of a finite Mind, and rightly disposed Body. But forasmuch as these two Parts are wholly of a distinct Nature, without any Analogy between them, I thought fitting to consider them each apart, and handle them distinctly, that the several Proprieties of each might be the better known. Wherefore I set down the description of the most principal Parts of Mans Body, both Internal and External; give an Account of the Formation of the Birth in the Womb, and of its Animation; as likewise of Nutrition, the motion of the Heart, Arteries and Muscles, and of the Circulation of the Blood. Then follows Respiration, and how the same is performed in Man; and lastly, some things are added of the Increase and Decrease of Mans Body, its Temperaments, and different Ages. And forasmuch as the Senses do chiefly belong to Man, I treat first of the Senses in common, and shew that they are the Effect of

The Sixth Part,
Concerning the
Four Bodies.

The Seventh
Part; Of Living
Creatures.

The Eighth
Part; Of
MAN.

The P R E F A C E.

the Nerves, and that the Soul of Man feels only, forasmuch as it resides in the Brain: Then I speak of the Senses in particular, viz. of Feeling, Tasting, Smelling, Hearing, and lastly having said something concerning the Eye and its Object, I Discourse concerning Sight, the most Noble of all the Senses, and of the manner how it is performed, and shew how the Scituation, Distance, Magnitude and Figure of Bodies are thereby discerned; and then add some Chapters of Waking, Sleep and Dreams; the Appetite of Hunger and Thirst; of the Common Sense, Imagination and Memory; of Health and Sickness; and lastly, of Medicaments in general, and their Operation.

The Ninth
Part; Of the
Mind, or Soul
of Man.

I look upon the Rational Soul as the Chief Part of Man, which excelleth the Body in its Nature and Functions; I evince that the same is more evidently perceived by us than the Body, since we cannot doubt of its existence even at the very instant we are doubting of it: For it is a Thinking Being, not only potentially, as some conceive, but actually; because Thinking can't be separated from it without the destruction of its Nature; whence I Argue, that it is essentially distinct from Material things, which consist in extension, and consequently that it is Spiritual and Immortal. Now as to the manner of the Union of these two Substances in Man, I briefly assert, that the same consists in this, that the Functions of the Body depend on the Cogitations of the Mind, and they again on the Motions of the Body, which Miracle is the work of the All-wise and Omnipotent GOD alone, as the Immortality and Eternal duration of the Soul is the effect of his Good pleasure. I prove that there are inborn Idea's in the Mind of Man, especially of GOD, a Thing, Substance, general Maxims of Truth, Good, Equity, &c. and explain the four Faculties of the Mind of Man, viz. Understanding, Imagination, Will and Memory; not as Things really distinct from it, but only as so many Modes, whereby it Understands, Imagins, Wills and Remembers.

And because the Affections and Passions are the consequence of the close Union there is between the Soul and Body, I shall in the next place handle them, and endeavour to lay down in short their Nature, Causes and Effects; and tho' there be many of them, and according to the variety of their Objects, are called by several Names, yet they have all of them but one and the same common Principle, to wit, the Animal Spirits, by the Motion whereof they are produced and strengthened. For all of them (if we except Admiration) are conveyed to the Brain, and are always accompanied with a peculiar dilatation of the Blood. I enquire also in what part of the Body the Soul entertains its Passions; what Love is, what Hatred, what Joy, and what Sorrow. Lastly, I undertake to assign the Cause of these Inclinations which are peculiar to certain Persons, and to which some give the Names of Sympathy and Antipathy, which I deduce from those Motions, that by some external Cause are excited in the Body from its first Infancy, and are apt afterwards to awaken the same Thoughts in the Soul; as on the other hand likewise the same recurring Thoughts produce the same Motions in the Body.

The Tenth and
last Part;
Concerning
the right Con-
duct of Life.

Last of all, this PHILOSOPHY is concluded with a Discourse of the right ordering and guidance of Life, the Happiness whereof doth not consist in Bodily pleasures, the Goods of Fortune, or the Gifts of the Mind; but in a firm unshaken purpose and resolution of well-doing, and in the satisfaction which thence ariseth. And because no Body can be said to do well, but he that acts according to Vertue, I proceed to the Explication of VERTUE in general, and unfold its Essence, shewing that it doth not consist in a Mean of the Affections, but in a constant pursuit of what seems best to Right Reason; and then pass on to the several Species of it, viz. Prudence, Temperance, Fortitude and Justice, which are so many Foundations of Human Happiness. I have not thought it any Crime in the handling of them, to depart from the received Custom of the Schools, and to Exhort my Readers rather to Doing than Talking, as knowing that Vertues are not acquired by Questions or Divisions, but by Precepts or Rules for the Forming of our Manners. I have also added some Articles concerning the use of the Passions, which I conceive to be of no small Advantage to the obtaining of Human Felicity, as long as they continue under the Guidance of Reason, and without Transgressing any of its Laws. And forasmuch as all Vertue would be in vain, in case Man were deprived of Free-will, I endeavour to prove, that Man was created Free by God, and that his Præscience and Power, is no hindrance to Human Liberty, and that notwithstanding the same, a Man may exert Actions worthy of praise or reproach.

But because these ETHICKS might appear defective without saying something concerning Human Actions, I thought fit to add a few things concerning the Duties, or Offices of Man in general, and of a good Citizen in particular; wherein I first discourse largely enough concerning the Rules of Human Actions, whether they respect GOD, our SELVES, or our NEIGHBOUR, and tho' in these Three all Human Obligations seem to consist, yet have I not thought much to superadd to these some other Laws of Humanity, and Rules of Covenants and Contracts, whereby all Persons, whether they be in a publick or private Station, may be informed what they are bound to do, and which be the Offices and Duties of Human Life.

Altho

The P R E F A C E.

Altho' throughout this whole Philosophical Work I have endeavour'd to observe a due Order, and to deduce subsequent Truths with all possible clearness from those that precede, yet I thought it would not be besides the Matter, if I should subjoin some Rules for New Beginners in PHILOSOPHY to observe, in order to the Securing them from Error, and for the right conduct and guidance of their Reason.

First RULE, That they lay aside all the Prejudices of their Infancy, and admit nothing for Truth, which they have not first discuss'd and examin'd anew.

Second RULE, That they be not rash in their Judgments, but always abstain from Judging, as long as they have no clear and distinct Perceptions; and that they neither affirm or deny any thing, except it be of Things that are clearly and distinctly known by them.

Third RULE, That they give great heed to the Question propounded, and warily consider, whether what they suppose themselves to have perceived, do necessarily follow from those Truths, which by a new Examination or Scrutiny they have found out.

Fourth RULE, To distribute the Difficulty they undertake to Examine into so many Parts, as fitting for the more easie and commodious resolving of it.

Fifth RULE, So to dispose the Members of this Division, as to begin with those that are most simple and easie to be known; observing therein the Order of Nature, as far as may be, and so by degrees proceed to the knowledge of such as are more difficult and compound.

Sixth RULE, To examine all the Parts singly by themselves, with so much Attention and Exactness, that they may be assured of having omitted none; and especially minding, whether they do not oppose and contradict those first Truths and primitive Notions they have already discovered, and clearly perceived.

Thus having gone through the Book of the INSTITUTION, next follows the HISTORY OF NATURE. For seeing that the Truth of the Principles of any Science is made manifest by the Evidence of its Deductions, and that their Certainty is look'd upon as Indubitable, if those Things that are Inferred from them, do wholly depend upon the knowledge of them; I was desirous to try, whether the several Appearances of Nature, or all those Things which our Senses perceive to be in Bodies, did comport with the Principles laid in my INSTITUTION OF PHILOSOPHY, and whether there be such a Connection between them, as that tho' the latter may be Apprehended without the former, yet the former can never be Understood without the latter.

For tho' the Principles I make use of in the Explaining of Things Natural seem to be very plain, as being nothing else but the Magnitude, Figure, Motion, Rest, and Position of Bodily Things; nevertheless I dare affirm, that in this NATURAL HISTORY I have had recourse to no other Principles; and that I have not only explain'd all those Effects, which by the Peripateticks are commonly look'd upon as the Miracles of Nature, without the Auxiliaries of Sympathy and Antipathy, or the assistance of occult Qualities; but have also given a true and Natural Reason of them, so as to leave no room for doubting of their Certainty, especially if it be considered, how many Things concerning Bodies, Qualities, Metals, Animals, &c. are unfolded and cleared from so few and such simple Principles, which certainly could never so well cohere together, except they were true, and out of the reach of doubting.

I confess I have chiefly taken upon me to explain the common Phenomena, and such as most frequently occur; yet must it not be thence infer'd, that I can't with the same ease render a Reason of the more extraordinary, which do seldom happen; since the Cause of all Effects is alike, and forasmuch as whatsoever we meet with in the World hath its Use and End from the same Principles. Wherefore I have generally forbore mentioning such as those, lest I should seem to stand in need of strange and uncommon things, to demonstrate the Certainty of my Principles, or to have recourse to Monsters and Prodigies to be my Witnesses of their Evidence.

My Design therefore in this Work was, not to describe the whole HISTORY of NATURE, or to comprehend in One Book all the Phenomena of the Universe, since that would be an infinite Task; but only to make out, that all the Things we see do perfectly well agree with the Principles I have establish'd in my INSTITUTION of PHILOSOPHY; and that nothing is handled by the Philosophers of any Sects whatsoever, which is not accommodately, yea, more distinctly and clearly explained by these Principles.

The First Part therefore I begin with is the Nature of a BODY, and at the very beginning endeavour to prove against EPICURUS and the most Famous GASSENDUS, that there is no empty Space to be found between the Parts of Matter: That the Arguments and Experiments which they alledge for the proving of a Vacuum are to no purpose, and wrongly applied. And in the next place proceed to the Affections of Bodies; where, after I have asserted the indefinite Divisibility of a Body, I lay down several Experiments of Bodies, Thin and Close, Hard and Fluid, Rough and Smooth, Transparent and Dark, Bended and Comprest, assigning the true Reason of their several differences.

And

The P R E F A C E.

The Second
Part is, of Qua-
lities.

And forasmuch as Qualities do always accompany Material Substance, and affect and determine the same in whatsoever State the same may be; I was willing to demonstrate the true Nature of them by Experiments, shewing that they consist in Quantity, Motion, Figure, and Position of Parts; which afterwards I make manifest by the Examples of Heat and Cold, Heaviness and Lightness; Taste, Smell, Sound, Colour and other Affections of Bodies which strike our Senses. Which done, I discover those Effects which are commonly attributed to unknown Qualities, which they term Occult, and declare the Causes of them.

The Third
Part is, of the
World and
Heaven.

Afterwards I proceed to the History of the WORLD and HEAVEN, taking my rise from the Beginning of the World, which is followed by the Generation of Things, and the Ordering of the several Parts of the World, with the end that threatens it from the Generation and Corruption of Things: After these come the Phænomena of the HEAVEN, SUN, and FIXT STARS, and the Spots that appear in their Bodies: And next to these the PLANETS and COMETS: And then from various Examples enquire, whether they have any Power upon us, or Inferior Bodies, or Foretell any thing with Certainty, and declare what we ought to judge of these kind of Predictions.

The Fourth
Part is, of
the Four
Bodies.

The Fourth Part is taken up by the Four great Bodies: First, The EARTH, which is almost to be look'd upon as nothing, if compared with the Universe: Next, the WATER, with its various Properties: Then the Rivers and Fountains, whose rise is discovered; and after those the Sea, with the Cause of its Ebbing and Flowing: These being the Things that have not only troubled the Heads of the Philosophers of this Age, but also those of the Ancients, and forced them to betake their refuge to occult Qualities. Next to the Water, the Phænomena of the FIRE are discovered, the Effects whereof are very different, as Earthquakes (which don't affect the whole Globe, but only some part of it) Glafs and Coals, which are produced by its Operations; and many other Things are Explained, not only of those which are generated here with us on the Surface, but also in the inward Parts of the Earth. And lastly, the AIR brings up the Rear of the Elements, whose power and efficacy appears as well in Natural as Artificial Things.

The Fifth Part
is, of Fossils.

And forasmuch as the Earth doth hide many Things in its Bowels, which deserve our Consideration, I have added something concerning FOSSILS, viz. Things dug out of the Earth in general: And first of Quicksilver, Brimstone, Salt, Gold, Silver, Tin, Lead, Brass, Iron, and other Minerals, whose Generation is no less wonderful than their Operations and Effects. This done, I proceed to the Stones, and having discussed their various generations, I examine their distinction and different Constitution: And lastly, consider the LOAD-STONE, which tho' it be reckon'd amongst common Stones, and hath nothing of lustre, yet has very singular effects, and such as are astonishing to those, who do not own the Striate or Screw-like Matter to be the Cause of them.

The Sixth Part
is, of Meteors.

After this, I proceed to the discovering of the Phænomena of METEORS, whose place as it is between the Earth and the Stars, so they seem to participate of both their Natures. First, I open the Nature of Vapours and Exhalations, and what goes to the forming of them: Then speak of the WINDS, which like wandering Travellers never rest. These are followed by Rain, Hail, Snow, Dew and Honey; and then I declare the rise and effects of TEMPESTS and THUNDER; also why LIGHTNING is so fierce, and why it seizeth hard Bodies without touching those that are soft. Amongst Meteors, the RAINBOW challengeth the first place, and other Fires kindled in the Air, which as they do more closely or loosely stick to their Matter, so they vanish sooner or later.

The Seventh
Part is, of
Plants.

After these comes the Seventh Part, concerning PLANTS, whose variety is almost infinite; where first I discourse of their Parts, Virtues and Qualities, whether hid or manifest, that are common to every Plant. Then I explain the Sympathy and Antipathy of some of them, adding something of their rise, nutrition, germination and decay, as much as may seem sufficient not only to understand their Phænomena, but also their whole Nature.

The Eighth
Part is, of Ani-
mals.

I begin my Treatise of ANIMALS with those that are begot of themselves, or as others will have it, begot of putrefaction, and from them proceed to Animals that are produced from Seed. And having enquired into the Cause of MONSTERS, I speak concerning their different Time in bringing forth; and then passing over to their Affections, I search into the Causes of HUNGER and THIRST, and of the CIRCULATION of the BLOOD; and then consider what it is in them that is the Principle of such various Operations, and make out that they are performed in them Mechanically, without any perception or knowledge; why some of them hate, and others love one another; and lastly, why some sleep more, and others less; and why they are subject to different Diseases.

The Ninth
Part is, of
MAN.

This whole History is concluded with MAN, who in the becoming Form of his Body excels all other Creatures of the World, as well as he exceeds them by his Reason, Understanding, and his Soul or Mind: For tho' he makes use of the same Organs of the Senses, with other Animals; yet he doth not perceive the Objects of them as they do, since Sensation is a kind of Cogitation in him,

The P R E F A C E.

him, which is not compatible to Brutes. And thus having explained some Experiments concerning Feeling, Tasting, Smelling, Hearing and Seeing; I proceed to Imagination and Memory, and lay open the Cause of Sleep and Dreams. And lastly, having described the Causes of Passions that outwardly appear, I Conclude this my Natural History, with the peculiar Natural propensities and aversions of some Persons, the Original whereof tho' of long time hid, is now made plain and perspicuous.

The Third and Last Book, is of the want of **SENSE** and **KNOWLEDGE** in **BEASTS**; where, tho' from the Beginning of the World it hath been the Common received Opinion, that Brute Beasts are endowed with Sense and Knowledge, and consequently that they are but gradually distinguish'd from Men, yet I make no scruple in this Discourse, to deprive them of those Operations, and to render them meer Machins, which by the furniture of Organs they are provided with, exert their several Actions, and perform all those wonderful things which most Men think can't be done without Knowledge. For seeing that Sense and Knowledge do include an immediate Consciousness of Perceptions, which it is Contradictory to suppose in the most subtil or refin'd Body that may be, I think that Beasts ought to be deprived of them both, and that they are neither more nor less than meer Engins or Machins. But what will some say; Have not the Beasts then any Senses or Appetites? Yes, they have; but without understanding or knowing what they do so feel or desire: For this is the peculiar Excellency of **MAN**, whereby he exceeds Beasts. For in them is nothing to be met with besides several Motions, which may as well be found in an Artificial Machin, as has been seen in the Flight of an Artificial Fly, and in that Iron-Statue, which after many Turnings and Windings presented it self before the Emperour of Morocco, kneeled down, delivered a Petition, and then rising again, returned the same way it came, as Historians assure us. Accordingly it will appear, that all those Motions which we perceive in Beasts, are only determined by the Animal Spirits, with the help of the Nerves and Muscles, and are performed in the same manner, as in us, when we do any thing without minding or knowing what we do: For indeed tho' such Actions be done in us, yet they are not properly done by us; wherefore I allow no Soul in Beasts, besides the Blood, which being a fluid Body, and swiftly moved, its more subtil part, which we call Spirit, and continually is carried by Arteries to the Brain, and from thence into the Nerves and Muscles, moves the whole Body, as I have fully here demonstrated.

Here is nothing more to be said, unless it be to acquaint the Reader, That tho' the Three Treatises contain'd in this Volume, have been well received in their former Dresses, both at home and abroad, having been often Printed here in England and in Foreign Countries, the last having been also Translated into French by Monsieur De **VILLEMESMES**, then Counsellor to the present French King. Yet to make them more useful to all Persons, I have now carefully Reviewed, Altered, and Enlarged them all; so that this whole Work, in all its Parts, is more Compleat and Perfect, than what has hitherto been Published in any Language.

Anthony Le Grand.

THE

The PREFACE

him, which is now deposited in the hands of the printer. And then having explained some Experiments concerning the Senses, I proceed to the History of the Senses, and lastly, having described the various Passions, I conclude this my Natural History, with the peculiar Natural properties and various actions of the Original subject, the Original subject, it now remains to be seen, what manner of person it is.

The Third and Last Book, is of the nature of SENSE and KNOWLEDGE in BEASTS. where, from the beginning of the World it hath been the common received Opinion, that Brute Beasts are endued with Sense and Knowledge, and consequently that they are the proper objects of the human mind. I make no scruple in this Disquisition, to describe them of those Operations, and to render them more Machines, which by the furniture of Organs they are provided with, than their former Actions, and perform all these wonderful things which we Men think can be done without Knowledge. For seeing that Sense and Knowledge do imitate an immediate consciousness of Perceptions, which it is Contradictory to suppose in the worst of Brute Bodies that may be, I think that Beasts ought to be deprived of them both, and that they are neither more nor less than mere Engines or Machines. But what will you say? Have not the Beasts then any Senses or Appetites? For they live; but without understanding or knowing what they do for or desire: For this is the peculiar Excellency of Man, whereby he exceeds Beasts. For in them is nothing to be met with besides several Motions, which may as well be found in an Artificial Machine, as in the flight of an Artificial Fly, and in their Iron Stears, which after many Turnings and Windings, presented it self before the Emperour of Morocco, knocked down, delivered a Portion, and then rising again, returned the same way it came. As Historians assure us. Accordingly it will appear, that all these Motions which we perceive in Beasts, are only determined by the Animal Spirits, with the help of the Nerves and Muscles, and are performed in the same manner, as in us, when we do any thing without minding or knowing what we do: For indeed the last Actions be done in us, yet they are not properly done by us; therefore I allow no Soul in Beasts, besides the Blood, which being a fluid Body, and easily moved, its more subtil part, which we call Spirit, and continually is carried by Arteries to the Brain, and from thence into the Nerves and Muscles, moves the whole Body, as I have fully here demonstrated.

There is nothing more to be said, unless it be to acquaint the Reader, That the Three Treatises contain'd in this Volume, have been well received in their former Editions, both at home and abroad, having been often Printed here in England as in Foreign Countries, the last having been also Translated into French by Monsieur De VILLEMESME, then Counsellor to the present French King. Yet to make them more useful to all Persons, I have now a second time Revised, Altered, and Enlarged them all; so that this whole Work, in all its Parts, is now Compleat and Perfect, than what has hitherto been Published in any Language.

Anthony Le Grand.

Figures or Schemes in the Institutions of Philosophy. Platz 2.

The First Part: OF THE INSTITUTION OF PHILOSOPHY. CONCERNING LOGICK.

INTRODUCTION.

CHAP. I.

Of the Nature and Constitution of LOGICK.

I.
What we
are to un-
derstand by
the word
LOGICK.

FOrasmuch as the Mind of Man is obnoxious to many Errors, as well in the searching out of *Truth*, as in the pursuit of that which is *Good*, in both which it is frequently mistaken; two *Arts* have been found necessary, whereof the former might direct the *Will* in the choice of the *True Good*, and the latter assist the *Understanding* in the discovery of *Truth*. The first of these, called *ETHICKS*, is an help to human Infirmary, directing the *Mind* of Man in the prosecution of *Good*, and shewing it what it ought to embrace, and what to avoid; the other called *LOGICK*, is the *Rule* of Man's *Thoughts*, which he is to observe in the framing of them, and by means whereof he may communicate his *Perceptions* and *Judgments* to others.

II.
The Defini-
tion of
Logick.

For *LOGICK* is nothing else, but the *Art* of *right Thinking*, or of *using our Reason aright*; where by the word *Thinking* we do not only understand simple *Idea's* or *Notions*, but also *Judgments* and *Discourses*: For he who *Reasoneth* or *Judgeth*, thinks as well as he, who only attends to simple *Notions*. So that *Logick* extends it self to all kind of *Thoughts*, and gives *Rules* to all the *Actions* of the *Mind*; because *Discoursing*, *Judging* and *Conceiving*, are but so many different *Modes* of *Thinking*.

III.
Why Lo-
gick is
called the
Art of right
Thinking.

It is to be observed, that *LOGICK* is not simply said to be the *Art of Thinking*, because *Thinking* is *Natural* to us, and the spontaneous products of our *Mind*; but the *Art* of *Thinking aright*. For since *Thinking* may be performed

well or ill, there is need of an *Art* that may rightly direct the *Actions* of the *Mind*, and prescribe *Rules* for the discerning of *Truth* from *Falshood*. For as the *Art* of *Husbandry* teaches the convenient ordering and disposing of those *Plants*, which otherwise grow of themselves and at random: So *Logick* furnisheth us with *Rules* to define *Things*, to sort them under their *General Heads*, and furnish them with their *Adjuncts*.

Wherefore *LOGICK* may be said to be the *Art of Knowing* each *Knowable* that can be the *Object* of Human *Understanding*: Not that it informs the *Mind* of the *Things* themselves, for that is the *Duty* of *Natural Philosophy*; but because it discovers the *Ways* of *right knowing* in general, and delivers those *Rules* by which the *Mind* of Man may be directed, whilst it endeavours to know any thing; so as not to wander from the *Path* of *right Reason*.

Now, that a Man may use *right Reason*, and be able to frame his *Thoughts* aright, and interpret them to others; it is necessary for him to *Perceive aright*, *Judge aright*, *Reason aright*, and *Order aright*.

We are said to *perceive* a thing, when we clearly and distinctly conceive the *Object* offer'd to us: First, so As when we represent to our *Thoughts* *God*, an *Angel*, a *Circle*, a *Triangle*, and stop there, without forming any *Judgment* concerning them. And the *Form*, by the immediate perception whereof we are conscious of our knowing any *Object*, is called an *Idea*.

For by the word *Idea* we are not to understand any *Representations* impress'd upon our *Senses*; but those *Images* of *Things*, which the *Mind* frames by *Thinking*. For the easier apprehension whereof we are to observe, that in the *Idea* or *Notion* of a

IV.
How Lo-
gick assists
the Mind.

V.
Four things
required to
the use of
right Rea-
son.

VI.
First, so
Perceive.

VII.
What we
are to un-
derstand by
the word
Idea, or
Thing
Species.

Thing two things are to be consider'd: First, That it is a *Modus* inherent in the *Mind*, from whence it proceeds: The other, That it shews or represents something. The former of those proceeds from the *Mind*, as its effective Principle; the latter from the *Object*, or thing apprehended, as from its Exemplary cause. So that when we frame the *Species* of any thing by Thinking, that first view of our *Mind*, by which it represents and conceives the Thing as present, is called *Perception*, or in other words, *The first operation of the Mind*, or *Simple Apprehension*. So that this *Perception* is said to be Simple, not with reference to the *Object*, which often is complex (as when the *Sun* is considered as a *Light* or *Lucid Body*;) but with respect to the *Modus*, under which the Thing is conceived.

VIII. We are said to *Judge*, when we affirm or deny any thing of the said known *Objects*; or when we by the Action of our *Mind* joining two *Idea's*, assert the one to be the other; or deny the one of the other. As when considering the *Idea* of the *Sun* and that of *Fire*, we affirm the *Sun* to be *Fire*, or deny the *Sun* to be *Fire*.

This way of Thinking is different from the foregoing, forasmuch as this is not the Simple apprehension of a thing; but a Compound, viz. an *Affirmation* or *Negation*, and is commonly called a *Proposition*, because the *Mind* thereby propounds its Sentiment of Things. It is also called *Judgment*; forasmuch as by this Mode of *Perceiving*, we do not barely apprehend a thing, but also judge or determine what it is, or is not.

IX. To *Reason* or *Discourse* is that Action of our *Mind*, which frames a *Judgment* of many others, or which from two *Propositions*, or from one, infers another: As for Example, After it hath judged that a *Body* is a Substance extended in Length, Breadth and Depth, and that *Heaven* is a *Body*; infers the *Heaven* to consist of three Dimensions.

So likewise observing that the *Idea* of a *Man* agrees with that of an *Animal*, but doth not agree with the *Idea* of a *Plant*, concludes, That therefore neither can the *Idea* of a *Man*, suit with that of a *Plant*. Wherefore finding that *Man* is an *Animal*, and that an *Animal* is not a *Plant*, it infers this Third *Proposition*, that therefore *Man* is not a *Plant*. This way of Thinking is call'd *Discourse*, because by running from one *Proposition* to another, it comes to a Third.

X. To *Order* is an Action of the *Mind*, whereby many things found in the same Subject, are disposed in a fit and congruous manner: As when the *Mind*, after it has fram'd several *Idea's*, *Judgments* and *Argumentations*, digests them in the most convenient and fit manner, for the ready and distinct conceiving of them.

XI. So that he that would proceed according to *Order*, must begin with those things that are more known, passing on to such as are less; and in the same manner proceed all along from one thing to another, so as that which goes before may always afford light to what follows.

If any one saith, That all these things may be done by the conduct of *Nature* only, since Experience shews, that such Persons sometimes perform them more exactly, who are wholly ignorant of the *Rules* of *Logick*, than they who have studied them: We freely grant as much, nor do we pre-

tend this Art to consist, in prescribing the *Modus* how those *Operations* are to be done, since *Nature* alone is sufficient to make us *Perceive*, *Judge*, *Discourse* and *Methodize*, without any foreign assistance. Yet is not *Logick* therefore to be judged useless, because it helps us to examine our Actions, and observe those Things which we do by *Natural* instinct.

As, First, that we may be assur'd that we use our *Reason* aright. Secondly, That we may with more ease discover the Mistakes, or supply the Defects, that may intervene in our *Mental Operations*. For it oft happens, that by the sole Light of *Nature* we are aware of some *Falshood*, and yet are ignorant where that *Falshood* lurks. As we find that Men ignorant of the Art of *Limning*, are often offended with a Fault they see in a Picture; tho' they cannot make out what properly the Defect is wherewith they are displeased. Thirdly, That the Nature of our *Mind* may be the more distinctly known by us, whilst we observe and give good heed to those Actions that are proper to it, and which vastly raise it above all Bodily things. Wherefore seeing that the *Mind* suffers it self sometimes to be impos'd upon by false Representations, it has been found necessary to prescribe some *Rules* by which it might be assisted in its Operations, in order to a more certain reaching of *Truth*. And accordingly the whole aim of *Logick* is to inform us, how we ought to make use of our *Reason*, and what Evidence we ought to have, before we give our Assent or Dissent to things, which by *Idea's* are presented to our Understanding.

Whence follows, that *LOGICK* is to be divided into Four Parts, according to the divers Reflections we have of these Four Operations of our *Mind*. The First, concerning *Idea's*, or the Simple *Perception* of Things: The Second, of *Judgment*, or of *Propositions*, wherein is *Truth* or *Falshood*: The Third, of *Discourse* or *Syllogism*: The Fourth, of *Method*, or the *Orderly digesting* of our *Thoughts*, by which, as by so many Steps, we arrive to the *Modus* or Way of *Knowing*. Forasmuch as by the first we are led from *Inconsiderateness* to *Attention*; by the second delivered from *Doubts* and *Errors*; by the third we are accustomed to *Reasoning*; and by the last, we infallibly prove some *Truth*, or demonstratively persuade the same to others.

CHAP. II.

Of the true Use of *LOGICK*, shewing that *Logick* is useful and necessary to the Conduct of a Rational Life.

LOGICK was always in so great esteem amongst the Ancients, that some of them admir'd it as a thing inspir'd from Heaven; and look'd upon them as rais'd above the Condition of Men, who understood the *Rules* of it, and were dextrous in the practice of them. Wherefore *Cicero* tells us, that the *Contemplation and Knowledge of Nature* is, as it were, by a Wall or Rampart secured and defended by the way of *Reasoning*; by the *Judgment* of what is True or False; and by a kind of Art of knowing what is agreeable and comports with every thing, and what is contrary to them. And for this Reason the Philosophers of Old

Old have bestowed several Names upon it, and measuring the dignity of it by its Necessity, have called it, the *Medicine of the Soul*, the *Organ or Instrument of Sciences*, and the *Eye of the Mind*.

II. True it is, that LOGICK seems to have declined from its primitive Majesty, since it now chiefly considers *Forms*, and is in a manner wholly taken up with the Resolving of unprofitable *Questions*: Yet neither is it wholly to be undervalued upon that account, since those *Questions* exercise the Wit of Men, and are not a little conducive to the examining of the Difficulties we meet with in other Sciences. As *Geometricians*, by exercising themselves in the crabbed *Questions of Algebra*, which are altogether Abstracted, and of no use for the Conduct of Life, are nevertheless thereby disposed for the understanding of other difficult *Problems*, that are of great use in the Life of Man. In a word, which way soever we consider *Logick*, we shall find it to be of use, and in that regard not inferior to other *Arts or Sciences*.

III. This will be evident, if we consider *Man* in himself, and the *Diseases* he is subject to. For a Man consists of *Body* and *Soul*, which both of them have their *Infirmities and defects*. So that as *Physick* takes care of the *Body*, by removing *Sicknesses* that afflict it; so there is need of *Science*, that may assist the *Mind*, by dispelling of its *Darkness*. Wherefore *Logick* takes care for the *Soul's* health, and consequently is as necessary to the *Intellectual Life*, as *Physick* is to the *Body*: Nay, and is by so much the more excellent and necessary, by how much the Nobleness of the *Soul* exceeds that of the *Body*, and by how much its *Diseases* are more hidden and more difficult to be cured.

IV. Neither is there any great reason of Wonder, why *Physicians* are so much respected every where, and favour'd with Honour and Riches; whereas *Logicians* are commonly very despicable: For the reason of this is, because the *Diseases of the Body* do affect the *Soul*; whereas the *Disorders of the Mind* do only afflict it self, and communicate little or nothing of their Smart to the *Body*; whence it happens, that in a manner all Mankind choose to lead an *Animal Life*, and but very few do follow a *Spiritual or Mental Life*. To which may be added, that the greatest part of Men are little concerned about the Vices of the *Soul*, and being only intent on the Care of their *Bodies*, think themselves most happy as long as they are in *health*; and all this, because they are drowned in the *flesh*, and wholly addicted to *sense*.

V. It is Notorious, that we brought no *Science* into the World with us, but that the same is acquir'd by *Industry*, or received from *Masters*: But seeing there are few that are able to Teach us, and that they who undertake it are frequently deceived themselves; we must find out a *Method*, whereby we our selves may correct our Errors, and endeavour to mend our Faults.

VI. If you say, that our *Reason* is sufficient for this, whose property it is to know the *Natures of Things*, and to discern *Truth* from *Falshood*. I answer, That indeed *NATURAL LOGICK*, or the very force and strength of *Reason*, which we have by *Nature*, doth not a little conduce to the attaining of *Truth*: For it consults those *Rules* *Nature* herself has prescribed, and being informed thereby, examines its Operations and Discourses by them.

For to speak truth, we naturally follow almost all those *Rules*, which after long study and great pains taking, *Logicians* have delivered to us; so that *Nature* it self seems to have taught us the *Art of Reasoning*; but yet we find, that she is not sufficient to furnish us with all necessary Knowledge, except she be assisted by *Precepts*, and perfected by *Art*. Who can deny, but that the Faculty of *Painting* is born with *Man*; and yet *Art* is necessary for the right forming of *Images*. All Men are endued by *Nature*, with a power of Speaking and framing of *Words*, which yet will never be reduced to *Art* without Use and Exercise; since it is clear beyond doubt, that should an *Infant* from his Birth be left alone, it would continue *Dumb* all its Life, unless it were taught to Form *Words* and give them their due Sound.

VII. Thus *Galen* proves the Necessity of *Logick* against *Erasistratus* by this Argument; Either every thing follows from every thing, or not: If you assert the former, then it will follow, that because a *Crow* is black, and a *Swan* white, *Erasistratus* is a Fool and mad; if the latter, then you must grant there is need of *Art*, that may inform us what follows and what not. For we cannot make out that a *Consequence* is right, or a *Demonstration* good, without the assistance of *Logick*.

LOGICK therefore is to be distinguish'd into *Natural* and *Artificial*. *Natural Logick* is that force of the *Mind*, by which it rangeth its *Thoughts* and reduceth them to order, or else Discourseth spontaneously without observing any order. *Artificial Logick* is that which is acquired by Use and Practice, and at first took its rise, and increase afterwards from various Observations taken from the Actions of the *Mind*.

VIII. Wherefore tho' we bring *Natural Reason* along with us into the World, yet is not that sufficient to direct the Actions of our *Minds*: For we find that notwithstanding the Use of *Reason* we fall into many Errors, and labour under the Prejudices of Infancy; and therefore must conclude, that *Artificial Logick* is not only useful, but necessary to cure the Diseases of the *Soul*, and to direct and guide its Operations: Where, by the *Soul's* Diseases, I do not mean *Sins* and *Moral delinquencies*, the Cure whereof is endeavour'd by *Divines* and *Moralists*; but the Weakness of our *Mind*, in the Perceiving of Things; viz. all manner of Errors, Confusions and Obscurities of our Conceptions; False and uncertain Judgments, and undue Consequences in our Reasonings, the discerning and removing whereof is the whole business of *Logick*.

IX. There is another common Division of LOGICK into *Doctrinal* and *Practical*. *Doctrinal Logick* is that which delivers the several *Rules*, directing us in Perceiving, Judging and Reasoning. *Practical* is that which applies those *Rules* to Use and Practice: For which reason the Ancients called the former *Abstracted* or *Separate from Things*; but this latter, *Concrete* or *joyned to the Things* themselves we are discoursing of.

X. There is another common Division of LOGICK into *Doctrinal* and *Practical*. *Doctrinal Logick* is that which delivers the several *Rules*, directing us in Perceiving, Judging and Reasoning. *Practical* is that which applies those *Rules* to Use and Practice: For which reason the Ancients called the former *Abstracted* or *Separate from Things*; but this latter, *Concrete* or *joyned to the Things* themselves we are discoursing of.

The First Part. Of the Clear and Distinct Per- ception of the Mind.

SEing it is evident from the foregoing Dis-
course, that there are Four Parts of *LO-
GICK*, correspondent to as many distinct
Operations of the Soul, about every knowable Ob-
ject: We will here begin with the First Part of it,
which directs the simple Perceptions and Appre-
hensions of our Mind. And to perform this the
more effectually, we will endeavour to take out of
the way the several Hindrances of Science.

CHAP. I.

What the Hindrances of Science are, and
how to be removed.

THERE are Two things by which we are easily
led aside into the By-way of Error and *Falsi-
hood*, viz. *Prejudice*, which makes us take up any
thing for *Truth*, before *sound Reason* hath con-
vinced us of it; and *Slavishness*, by which we are
so addicted to the Opinions of others, that we think
it a Crime to differ from them.

Wherefore it is no wonder that we find so few
Men truly Wise, and who know the Causes of
Things aright, seeing they scarce consider any
Thing well and duly throughout their whole Life,
and do not so much give their assent to Right
Reason, as to their *Prejudices* and the Testimony
of their *Senses*. For the force of *Prejudices* is so
prevalent with some, that they cannot admit any
thing for *Truth*, which is not grounded on those
false Opinions they have suck'd in from their *Cra-
dles*. Wherefore it will be worth our while to shew,
how vain the Things are we then know, and that
we ought to distrust and suspect whatsoever proceeds
from such weak Causes. For what did ever any *Infants*
perceive, which they did not wholly refer to their *Bo-
dies*, and which they did not desire or dread, accord-
ing as they fancied them hurtful or grateful to the
same? Thus we see they are pleas'd with the Light
and Shining things, because *Refulgency* with its Beau-
ty pleaseth their Eyes; whereas they dread a *Rod*,
because with it they are chastis'd and put to pain.
Wherefore *Children* judge of things, as they appear
to their *Senses*; As that the *Earth* is far bigger than
the *Sun*, and the rest of the Heavenly Bodies;
because the *Earth* is nearer to them, the other be-
ing at a great distance from them. Thus likewise
they think, that there is more Matter in *Lead* and
other Metals, than there is in *Fire* or *Air*; because
they find more Weight and Hardness in the one
than the other. And again, because they perceive
no more Brightness from the fix'd Stars than from
the small Light of a *Candle*, they are apt to think
that the Stars do not exceed the bigness of a *Can-
dle*, and therefore fancy them as so many bright
and shining *Studs* fix'd in the Firmament of *Hea-
ven*; whereas there is no *Natural Philosopher* but
knows, that the fix'd Stars are equal to the *Sun*
both in Bigness and Brightness.

Now these Errors are not only to be found in
Infancy, but in process of Time they get strength,
and become so rooted into Mens Minds, that they
accompany them the whole course of their Lives.
Hence it is that we meet with some that have the

Gravity of *Old Age*, but at the same time are subject
to the Weakness of *Children*. Which Mistakes arise
from hence, because they suppose that the Opinions
they have taken in during their *Childhood* and
Youth, are inborn *Notions*, and common to all
Mankind. Whereas they ought to consider, that
they have admitted many things for *Truth*, without
any sufficient Examination, and that therefore they
ought rather to think them to be false than true.
But the case is the same with them, as with those
that have Sore-Eyes, who delight in *Darkness* and
are offended with the *Light*; for they hug their
Errors, and are loath to part with them.

Some of the *Philosophers* of Old were not free
from this Weakness, who asserted the *Sun* not to be
above two Foot over, because they had never seen
it greater. And it was to no purpose to persuade
them by *Astronomical Arguments*, that it was not
only far greater than so, but many times bigger
than the *Earth*; because their preconceived Opin-
ion was so rooted in them, that they could no
otherwise apprehend it. Thus likewise when they
were *Children*, and thought of nothing but what
was Bodily, they thought nothing could be Cor-
poreal, but what must be Sensible also, from which
Prejudice they concluded afterwards, that there
could be no *Insensible parts*. If one argues against
this, that such Parts must of necessity be admitted
to avoid a *Vacuum* in Nature, and for the Explica-
tion of many *Natural Appearances*; they have no-
thing else to answer, but that they cannot see them,
and that they are not certain of any thing, except
it fall under their *Senses*. From the same *Prejudice*
it is, that they conceive all *Immaterial things* after
the manner of things Sensible, and apprehend the
Mind of Man, not as a *Thinking Being*, void of
all Matter, but like a *Wind* or *Fire* infus'd into the
Grosser parts of the *Body*, to which tho' they at-
tribute the Name of *Spirit*, yet conceive of it
under a Bodily likeness. Wherefore also they gree-
dily embrace that Maxim of *Aristotle*, That there
is nothing in the Understanding, which was not
first in the Senses.

If we go further and tell these Men, That God
doth not fall under any of our *Senses*, and there-
fore cannot be conceiv'd of under any sensible
Form; yet by reason of their Inveterate Custom of
false Judging, they rather chuse to frame several
Distinctions, than to forsake their beloved Maxim;
tho' only supported by *Childish Prejudices*; saying,
That God is made manifest unto us by his *Effects*,
or by some *Signs*, as by his *Creatures* and *Words* that
signifie his *Nature* unto us. Which *Prejudices* do re-
ally divert the *Mind* from the knowledge of *Things*,
and hinder it from ever attaining the true way of
Philosophizing. For how can we think ever to attain
it, if we always Judge after the manner of *Child-
ren*, and only believe those Things to be true,
which through the *Senses* are convey'd to us? How
can we ever think to make a right use of our
Reason, if we only take those things to be
good which are of Profit to us? If we think the
Air, *Cold* and *Heat* to be nothing, when they do
not sensibly affect us? Or, if we judge the *World*
to end where our Sight is bounded, and innume-
rable other Things, which the Love of Antiquity,
or the Authority of some Men have induced us to
maintain.

Education
and Cu-
stom lead
us into
Error.

Now all these *Prejudices* are much increased, by those Words which are in common use, and which the illiterate Multitude hath imposed; as having more reference to the Use of the *Body*, than to the Contemplation of Things. Moreover *Education*, *Custom*, and *Converse* with other Men, the *Authority* of those we reverence, the *Consent* of Mankind, and many other such like, hinder us from scanning of Things purely and sincerely, and lead us into many Errors. What hath once been prov'd to us, or believed by us, we scarcely ever reject, insomuch that the *Vices* and *Affections* of our Will, do communicate their contagion to our Mind and Understanding.

VII.
Hard and
difficult
things are
apt to
please us
more than
things
easie and
obvious.

Sometimes it happens on the contrary, that those Things which are clear and perspicuous of themselves, are suspected by us; because Things obscure and liable to dispute do more affect us. Thus we are apt to condemn Experiments, as being too despicable, and our *Mind* desirous to take a higher flight, and hating to be confin'd to the narrow bounds of an *Experiment*, chooseth rather to please it self with some General Notions, which for the most part are of no use at all; and so prefer swelling Words of *Vanity*, which fill the *Fancy*, before things real and solid. Hence it is, that the High-flown Expressions of the *Platonists* and *Chymists* do allure so many. Besides, we are apt to suffer our selves to be deceived by the respect we have for *Antiquity* as well as by our affectation of *Novelty*, as if a thing were therefore true, because it is either New or Old, as if True things had not always been so, as if in this old Age of the *World* we might not expect the discovery of many Things heretofore unknown, or as if we might not look for a riper Judgment, and more knowledge from Old Men, that daily Experience many things, than from others.

VIII.
We must
first exa-
min our
Opinions,
before we
lend an
assent to
them.

We are therefore to examine our *Opinions* by the Standard of *Reason*, before we give our assent to them; and must judge those things to be True, not which the *Authority* of the Ancients, or the Judgment of most Men doth approve, but which are evidenc'd to be so by the strength of *Reason*. For the obtaining of which the following *Rules* will be helpful to us, if we seriously mind them, and judge of Things propos'd to us, according to their direction.

CHAP. II.

Some Rules for the Attainment of Truth.

The First Rule.

We are to admit of nothing that involves any thing of Doubtfulness.

I.
Doubts hin-
der us from
the attain-
ing of
Truth.

THe Light of *Nature* assures us, that *Doubting* is an obstacle to *Science*; and that we can never attain it, as long as the thing we apprehend is not clearly and distinctly represented to our *Mind*. Wherefore we shall do well to esteem all *Doubtful Matters*, as if they were false, and despise them as hurtful *Images*, that are apt to lead us into Error. For seeing that all Things that are built on any *Principle*, derive all their Certainty from the same; if that *Principle* be weak and tottering, the superstructure must partake of the same Conditions.

II.
Yet must
not this be
too scrupu-

But tho' this *Rule* be of use for the clear knowing of Things, yet must we not extend the same to Human Prudence, or the use of Common Life.

For it often happens, that we are forced to embrace tushy ob- what is least suspected; and to esteem that as Good, serv'd in which doth least hurt another. Thus the Laws matters of wink at the Toleration of Whores, to prevent the daily busi- greater Evils of Rapes and Adultery. Thus in ness, in Human Actions we are forc'd to choose that which seems probable, and to leave that which is more true. But in the Search of *Truth*, whatsoever hath the least Doubt in it, is to be rejected, and is no more to be regarded than if it were a thing feigned at pleasure. For whatsoever doth not conduce to the attaining of *Truth*, must be look'd upon as a straying from it.

Wherefore he that would *Philosophize* in good earnest, must rid himself of all the *Prejudices* of his Infancy, forasmuch as they have crept into our *Minds*, without any foregoing Examination of *Reason*; and therefore are to be consider'd by us, as false, rather than doubtful. Hence it is that our *Philosopher* saith, I have now for some years consider'd how many false things from my first Childhood, I have taken up for True; and how uncertain and doubtful all those things are I have built upon them; and therefore that it were best once in my life to overthrow them all; and to begin again from the first Foundations, if ever I would desire to establish any thing in *Sciences* that might be firm and lasting.

Neither need we to fear, lest by taking all things for false, we should be in danger of being deceived; because this *Doubting* is only indulg'd for to attain to greater certainty, and that we may the more evidently distinguish *Falshood* from *Truth*. For whatsoever includes the least Doubt, destroys *Science*, as hath been said, and leads to *Error* as well as *Falshood* it self. Is it not lawful for the *Philosophers* to suppose many Things, that by this means they may find out what is most certain and easiest to be known? Thus the *Astronomers* imagin an *Equator*, a *Zodiack*, and other *Circles* in the Heavens, that by the help thereof they may the more accurately describe the *Sun's* Course. *Geometricians* also make use of the like Suppositions, when with new *Points* they measure *Lines*, and to the *Figures* given add other *Lines*. Wherefore it will be of advantage to those who search after *Truth*, to reject all things that occur to them, and to give their assent to those things only, which they understand to be Certain and Evident.

This way of Proceeding in the attainment of *Sciences* is not peculiar to *Descartes*, for *Aristotle* himself hath followed the same, as may be seen in the First Chapter of his Third Book of *Metaphysics*, which bears this Title; Of the Usefulness of *Doubting*, and what things we ought first to doubt of: Where he speaks thus; In order to our attaining the *Science* we desire, it is in the first place needful to take a view of those things we are first to doubt of; now such are all those things about which Men are divided in their Opinions, with other things besides. It being an Industry well worthy the pains of those who desire Knowledge, to Doubt aright. Wherefore we need not think strange, that our *Philosopher* begins his *Philosophy* with *Dubitation*, and requires us to reject all those Opinions wherein we meet with the least cause of *Doubting*, that by this means we may at last find out a true and unshaken Principle.

The Second Rule of Truth.

We are not to rely too much on our Senses.

I.
The Senses
are subject
to mistake
on several
accounts:
As,

Forasmuch as our *Senses* are deceivable, and we are frequently imposed on by them, Common Reason will tell us, that we must not overmuch trust to them, but rather suspect whatsoever they offer to us; for it is a sign of *Rashness* and *Imprudence*, to trust them that have once deceived us. Now how apt our *Senses* are to deceive us, daily Experience teacheth. For it happens often, and for divers Reasons, that things appear otherwise to our *Senses* than they are indeed.

First, By reason of their *Distance*, as when the Object is so far from us, that all the *Reflex Rays* proceeding from it, cannot whole and entire reach us: As for Example, The *Sun*, and a *Square Tower* at a distance seem less, and otherwise figured than indeed they are.

Secondly, By reason of the *Medium*, as when the *Rays* are variously refracted in the same: Thus a *Stick* and other Bodies seen through the *Water*, appear Crooked.

Thirdly, By reason of the *Surface*, which as it appears to the *Senses*, doth not represent the Essential position of the Parts of the *Body* whose Surface it is: Thus the outside or superficies of a *Bean*, which falls under our *Senses*, represents a Figure very unlike that of a *Plant*; whereas the *Microscope* discovers to us, That it hath the same Essential disposition of Parts with the whole *Plant*, whose Seed it is. So likewise the *Spawn* of *Frogs* appears to our Eye, to be an *Unorganical Mass*; whereas the said *Magnifying Glasses* assure us, that they are distinguish'd into several Members. And the same may be proved by many more Instances. Neither is it to be doubted, but that there be many *Bodies*; the Essential Constitution of whose Parts were never yet discovered to us by any of our *Senses*, which if they were, we should judge otherwise of them, than the *Vulgar* do.

Fourthly, By reason of the *Impression* made upon our *Senses*, when the *Vibration* (caus'd by the Object) doth for some time continue; As when the *Sun* appears to our Eye after it is shut; or as when a *Torch* is with great swiftness turn'd round, whereby a fiery *Circle* is represented to the Eye, tho' the *Torch* be not in all the Points of the *Circle*.

Or when the *Impression* proceeds from something else besides the Objects; as in *Dreams* and strong *Imaginations*, &c. or when an Angel (by moving the Organ of *Sight*) doth represent himself to us.

II.
This Rule
is not to be
extended
to the
Actions of
Life.

Which deception doth not only frequently happen to our *External Senses*, but even our *Internal Sense* is not free from it. Thus we see, that those who are troubled with the *Vertigo*, think that all the Bodies about them turn round, and suppose the Air to be darkned: Thus likewise *Drunken Men* see all things double. Now when it is said, that we are not to trust the Testimony of our *Senses*, but are to look upon them as if they were false; we are to observe that this Rule must not be transferr'd by us to the *Actions* of *Life*. For it is contrary to Reason, not to trust our *Senses* in the conduct of our *Lives*: For by this means we shall make our selves guilty of the Folly of those *Scepticks*, who out of a foolish distrust of their *Senses* were ready to expose themselves to eminent danger of their *Lives*,

but that their Friends hindred them. Tho' indeed, when the Question is about the bare knowledge of Things, then it is on the other hand every whit as Irrational, not to reject whatsoever is in the least doubtful; because things that are so, are as opposite to the attaining of *Science*, as those which are altogether false or unknown.

And tho' our *Senses* sometimes may represent to us Things as they are, yet must not this hinder us from suspecting their Evidence: For having once deceiv'd us, they may always deceive us; or how can we rely upon them, which have once led us into Error? And therefore *Plato* in his *Phædrus* tells us, That Men who are desirous of *Science*, know, always li- that Philosophy having once undertaken the Care of their Mind, does by little and little inform it, and loose it of its Bands; representing to it, how deceiving the Judgment of the Eyes, Ears, and other Senses are, persuading it to leave them, as far as absolute Necessity does not oblige us to close with them, and to recall it self, and to recollect within it self, without giving credit to any thing besides it self.

For our *Senses* are not given us by Nature for the searching out of *Truth*, or to contemplate the Principles of Things: Because if we take an exact view of the Objects of *Sciences*, we shall find that most of those things that occur to our Mind, are not represented by any Bodily Figure: As for Example, All the Objects of *Metaphysics* and *Natural Divinity*, which admit nothing of any *Corporeal Form*. For we have in our Mind an *Idea* of God himself, whose Authority we believe, and whose Dominion over all we firmly are persuaded of. For how could we demonstrate so many things concerning God, if his *Idea* were not inherent in us? But do any of our *Senses* hand this Knowledge of God to us? What *Phantasm* manifests to us the General Notions of *Entity*, *Unity*, *Truth* and *Goodness*? What Species represents to us the *Idea* of *Angels*, or our own *Soul*, since there is nothing like them in the whole Universe of *Material Beings*, and with which they have not any thing in common, save only the Name of *Substance*? Wherefore it is very absurd to go about to derive all Knowledge and *Idea's* from the *Senses*. And if from these we pass to *Physical* or *Natural Beings*, we shall find that not only the Beginning of them are hid from our *Senses*; but that not so much as their Figures are represented to us, such as they are indeed, but very different from what our *Souls* upon enquiry find them to be. Do not we reach the Nature even of those thing that most strongly affect our *Senses*, as *Light*, *Heat* and *Cold*, far better by our *Understanding* than by *Sense*? And are not many times the most sensible Objects the least perceptible to our Intellectual Sight?

The *Senses* therefore are bestowed upon us by Nature to discover to us, who consist of *Soul* and *Body*, what things are good or hurtful for us; and we pervert the order of *Nature* when we put them to another use, and apply them to the knowledge of *Truth*, which are only design'd for the Preservation of the Compound. Wherefore also this may be reckon'd amongst the chief Causes of Error, wherewith we are possess'd from our Childhood, that we are apt to judge of things, not as they are in themselves, but only as they gratifie or offend the *Body*.

VI.
Objection,
That the
Senses in-
form us of
many
things.

If any one object, That we attain to the know-
ledge of many Things by our Senses; that by our
Feeling we perceive Bodies, as Stones, Wood and
other things that come within the reach of our
Hands; by our Sight, things at a distance, as the
Sun, Moon, Stars, Heaven, &c. and that without
them we could never have any knowledge of these
Objects.

VII.
The Senses
do only
accidental-
ly discover
things to
us.

To this I answer, that I do not wholly reject
the Service of the Senses; but only assert, that they
are insufficient and inadequate for the knowledge of
Truth. For tho' the Senses may inform us that
Bodies exist; yet cannot they discover to us what
those Bodies are, or what their Nature and Essence
is; because this is not necessary for the Conserva-
tion of the Compound. And if ever they inform
us what they are in themselves, this is only some-
times and by accident. For seeing that our Senses
cannot perceive Corporeal things but through the
intervening Medium, it is evident, that according as
that is variously disposed, so their Judgment con-
cerning them must vary accordingly. Thus we
see that for this Reason the Stars appear to us of
various Colours, sometimes more red, and sometimes
paler, according as the Air that comes between our
Sight and them is clearer or thicker. And therefore,
as *Lucretius* saith, *Lib. 4. we have great reason to*
suspect, that the Inferences we fetch from our fal-
table Senses, must be false and deceivable.

VIII.
How our
Senses are
said to be
deceitful.

But when we say, that our Senses are deceitful
or subject to Mistake; we must not so understand
this, as if there were an Error in the Motion itself,
or in the affecting of the Corporeal Organ, because
that is done by a kind of Natural Necessity; but
because the Mind of Man, by reason of its inti-
mate Union with the Body, doth from that Affection
or Motion take occasion, to apprehend or judge of
the thing amiss. And forasmuch as this precipi-
tancy and inconsiderateness in Judging is commonly
attributed to the Senses, and not to the Mind; the
Senses are said to deceive us, because our Judg-
ments follow those Perceptions that are attributed
to our Senses.

IV

The Third Rule of Truth.

Whatsoever we Perceive, we perceive with our
Minds.

I.
Our Under-
standing is
the searcher
out of
Truth.

Forasmuch as Divine Revelation, or Human
Tradition, have no admittance in Philosophy, and
that according to the fore-going Rule, we are to
suspect whatsoever comes from the Senses; it re-
mains that the Understanding alone must be the
sole searcher out of Truth, whose property it is to
investigate the Natures of Things, and so judge of
them according to the Attributes that are found in
them.

II.
Not only
common or
general
Natures,
but parti-
lar also,
are known
by the Un-
derstand-
ing.

Neither is this only to be understood concerning
Essences, or Abstract Natures, as the Metaphysicians
call them; but of every particular Object that
strikes our Senses. For it is the Mind alone which
sees, hears and feels through the Organs. For Gold,
by Example, that is newly dug out of the Mine,
doth at first sight look like Earth, and before Coa-
gulation is more like Sand, than a Metal: But
after it is once cast into the Furnace, it loseth the
form of Earth, its parts run together and shine like
a Star; and what before lookt so much like Dirt,
now delights and pleaseth all Men. So that my
Senses at first perceived nothing of the Nature of

Gold; for whatsoever my Sight or Touch, before
discovered of it, is quite changed; the substance of
Gold still remaining.

Wherefore it is the Mind alone that knows the
Nature of Gold, neither can we discern what it is,
but by our Faculty of Judgment. We make no
scruple to say, we see a Man, when we see one
walking in the Market, tho' indeed we see nothing
but his Cloaths, under which possibly a meer Ma-
chin might be conceal'd. It is plain therefore, that
we do not make this Judgment by our outward
Eyes, but by our Faculty of Judging, which is
Internal.

To explain this by another Example; Our Skin
appears to us to be a continuous Body, without any
Holes in it that our Eyes can perceive; but yet our
Mind, by the Transpiring Sweat, concludes there
must be Pores in it, by this way of Reasoning:
The Moisture that is sent forth through my Skin, is
a Body; now a Body cannot pass from one place to
another without passing through a Medium; where-
fore it must follow that my Skin is like a Sieve or
Strainer; that is, of such a Texture, as to be full
of little Holes, through which the Moisture may
pass.

This Rule is so certain, that whosoever denies it
will never be able to attain any thing distinctly or
by Reflex knowledge, which is necessary to Science.
And though some relying upon Aristotle, suppose
all our Ideas to arise from our Senses, and that
there is nothing in our Understanding, which was not
first entertain'd in our Senses; yet it is evident, that
this Opinion, tho' common, is directly opposit to
Divinity and true Philosophy. For first, there is
nothing we perceive so distinctly as our Thoughts;
neither is there any Proposition that shews it self to
our Mind with fuller Evidence than this; *I think*
therefore I am; and yet neither of these Ideas
of Cogitation, or Being, were ever discover'd to us
by any Sense: Not by our Sight or Hearing, as
being without Colour or Sound; nor by any other
of the Senses, because they have no Sensible qual-
ities, or if they think they have, let them declare
them. But if they cannot satisfy us herein, what
remains but for them to own our Assertion, That
the Notions of Thinking and Being do not depend
on the Senses, but that our Mind forms them by its
own proper virtue or efficacy; tho' we do not deny
but the Mind may be sometime excited to the
forming of them by outward things that affect our
Senses.

Who can believe that the Idea of GOD, which
is in us, doth proceed from our Senses? Or shall
we think so, because some Ignorant persons conceive
him under the form of a Venerable Old Man, as
Gassendus tells us. But this is to confound and de-
prave Ideas, when we go about to imagin Spiritual
things under a Bodily form: And he is in as great
a Mistake, who would imagin Immaterial Substances
as he is, who would hear Colours and see Sounds.
It is apparently false therefore, that the Notions
which we have of Spiritual things do proceed from
the Senses; nay, what is more, it is certain that no
Representations of Material things come to our
Mind, save only occasionally; that is, forasmuch as
the Motions made in our Brains (for nothing but
Motions can affect our Senses) do give the Soul occa-
sion of forming several Notions, which without
them it would not do. Which Notions are also
wholly

III.

It is by the
Mind alone
we know
Objects.

IV.

It is by our
Under-
standing
alone we
know that
there are
Pores in
our Body.

V.

Many
things
cannot be
discovered
to us by our
Senses.

VI.

GOD can-
not be re-
presented
by any out-
ward Ap-
pearance.

wholly distinct from those Motions and Representations, which are in the *Brain* or *Senses*. For they who are *Blind* and *Deaf*, tho' they receive no Species or Sounds from the *Objects*, yet are not without the *Idea's* of *Cogitations*; especially when they reflect upon the things they are thinking of.

vii.
How the
Idea of Im-
material
things are
said to be
inborn in
us.

Wherefore seeing we can perceive nothing by our *Sense* or *Imagination* but what is *Material*, it follows that the *Idea's* of all other things that are not *Material*, are inborn with us; for by what other means could they be convey'd to our *Minds*? Yet when I assert that these *Notions* were put into the *Mind* in its first beginning, I would not be so understood, as if they did actually exist there, and were continually obvious to our *Thoughts*; but only that God hath vouchsafed a Faculty to our *Mind*, of exciting and producing such *Notions*; as shall be more largely treated in the *Ninth Part*, concerning the *Mind of Man*.

The Fourth Rule of Truth.

That is True which we know clearly and distinctly.

I.
Cogitation
is the Rule
of Truth.

Wherefore there can be no more certain Rule of *Truth* than our *Cogitation*, so that the same be but distinct and clear, and without the least Doubtfulness; because it is impossible for us to mistake, as long as the *Judgments* we frame of any thing do correspond to our *Perceptions*. It being an undoubted Axiom with us, *That our Knowing of a thing is a sure Argument of its Essence*. Not as if because we perceive the *Essence* of any thing, that from thence we should presently conclude that it exists: But because it is impossible that any thing which is clearly known by us, should not be such as it is known by us; that is, the thing must exist, if its *Existence* be perceived by us, or must be of this or the other Nature, if its *Nature* be represented to our *Mind*.

II.
From this
Principle
the Exi-
stence of
GOD is
proved.

From this Principle *Descartes* evidently demonstrates the *Existence* of *GOD*. For if upon the account only (saith he) that I have such an *Idea* in my *Mind*, it doth follow that whatsoever I perceive clearly and distinctly to belong to it, doth really do so; may I not from hence fetch an Argument for the *Existence* of *God*? Yes surely: For the *Idea* of *GOD*, represents a Being absolutely Perfect: Now it is every whit as repugnant to a Being absolutely Perfect, to want any Perfection, as for Example, *Existence*, as it is for a Triangle not to have three Angles equal to two right ones.

III.
Provided
it be clear
and dis-
tinct.

I said in the Beginning, provided our *Cogitation* be clear and distinct; because no Certainty can be expected from a thing, whose Knowledge involves the least degree of Obscurity or Confusion. And therefore *Plato* in his *Timæus* tells us, That when we discourse of a firm, stable, and intelligible thing, our Reasons also must be stable, immutable, and insuperable. For seeing that clear and distinct Knowledge is something which we our selves are not the Authors of, it must follow that *GOD* is the Author of the Connexion there is between clear and distinct Knowledge, and the assent which the *Will* infallibly yields to it. So that it is absolutely impossible, that what I thus apprehend to be true, should be false: As for Example, When I perceive Two and Four to be Six; that in a Triangle there

be three Angles equal to two Right ones; and the like. It is impossible these should be false; not because they are so conceived by me, but because except they were true, I could never have clearly or distinctly perceiv'd them.

For if any thing thus apprehended by me could be false, this would destroy all Human Knowledge; neither could any of us be sure of any Truth, nor of the *Existence* of *God*, nor of any of those things which are related to us in Holy Writ: Since it might still be objected to us, that those very things may be false which we most clearly and distinctly perceive.

But we cannot attain the same certainty of Knowledge in those things which are only perceived by the Senses, forasmuch as they are liable to Mistake: As when a Man, whose Eyes are deprav'd by a suffusion of Gall, takes all things he sees to be Yellow; and perceives the same as clearly, as those who see the true Colour of every thing.

It remains therefore, that all the Certainty we have, is only of those things which we apprehend with our Understanding. Neither doth it destroy this Rule, that some tell us they have sometimes been deceived even in those things which they thought to be most true, and which they were confident they had clearly perceived. For this happens to them, because they derive the clearness of their Cogitation, not from their *Mind*, but from their Senses, or from some preconceived Opinion: For we can never doubt of those things which we clearly and distinctly know. As will be evident to those who by frequent Meditation, and earnest Study, have acquir'd a habit of Judging between a clear and dark Conception.

We are also to take Notice, that when we assert that to be true which is evidently and distinctly known by us; and therefore that we are not to give our Assent to things that are not so known by us, this is not to be understood of Matters of Faith; forasmuch as they are not accompanied with any such Evidence, neither have we any clear Notions of them, as we have of the Subjects of Natural Sciences. For there is a vast difference betwixt the Mysteries of Faith and Natural things, because in these Evidence, but in the former Authority commands our Assent. That a Man may be a Believer, he must believe without Evidence; but to be a Philosopher, he must have a clear and distinct Perception.

If any Man demand, How he may be sure of his knowing a thing clearly and distinctly? I answer; If he follow the Order prescribed by right Reason; if he do not precipitate his Judgment, before he be enlightened with the Truth of Evident Perception. So that the Judgment of our Understanding must always go before, as it does when we never assert or deny any thing, except it be of Things we have clearly and distinctly perceived; that is, when our Judgment is exactly conform to our Perception. For it is not a sufficient Argument for us to embrace any Opinion, because there is Truth in it, except the same do appear to us; so as that our Perception may be the Rule and Line of Truth to us.

A Transition, containing the substance of what hereafter follows, concerning the clear and distinct Perception of Things.

IX.
The Order
or Series of
things to
be handled
in the first
Part of
Logick.

Forasmuch as it hath been made out, that the clear and distinct Perception of the *Mind*, is the one and only Rule for the attaining of *Truth*; it remains now that I shew, how the *Mind* may arrive to the same: Which that I may the more easily accomplish, the following Points are heedfully to be minded.

First, What *Cogitation* it self, or *Perception* is, and what be the Modes of it.

Secondly, What be the *Objects* of our Perceptions, whether *Universal* or *Singular*.

Thirdly, How our *Mind* may arrive to the knowledge or Perception of *Things*, with respect had to the *Things* that are to be known; such as are the *Common Attributes*, *Causes*, *Effects*, *Subjects*, *Adjuncts*, &c.

Fourthly, Whence the clearness and distinction of *Idea's* do depend, as likewise the Agreement and Disagreement of *Things*.

CHAP. III.

Concerning the various Modes of Perception; viz. Pure Intellection, Imagination and Sense.

I.
We must
never give
our judg-
ment of a
thing un-
known.

Forasmuch as *Natural Instinct* teacheth us never to judge of a *Thing* unknown; and since nothing is known to us but what our *Mind* clearly perceives, we will first treat of the Nature of *Cogitation*, before we examine that of *Simple Notions*, to the end we may be able to discern what things are confusedly, and what distinctly apprehended by us.

II.
What is to
be under-
stood by
Perception.

By *COGITATION* in General, I understand all those things which we experience in our Selves, and whereof we are Conscious: Which Description comprehends all the operations of our *Understanding*, *Will*, *Imagination* and *Senses*; for to *Understand*, to *Will*, and to *Imagine*, is nothing else but to represent to our selves the thing whereof we have an *Idea*. And accordingly from these various ways of Perceiving, is deduc'd that first *Truth*, which we meet with in an orderly way of Philosophizing: For because I *Think*, that is, because I *Perceive*, *Imagine* and *Feel*, it necessarily follows that I exist: And therefore that Proposition, *I Think, therefore I am*, is of undoubted *Truth*; since it is impossible that I should *Think*, and yet be *Nothing*. And so in like manner when I say, *I walk*, *I write*. Not as if *Walking* or *Writing*, which are perform'd by the Organs of the outward *Senses*, did infer my Existence, because I may think I perform them in a *Dream*; but only because the Consciousness which is in my *Mind*, of my *Walking* and *Writing*, could not be there without I did exist.

III.
Our own
Existence
is before
any other
Truth.

I have said, that this Proposition, *I Think, therefore I am*, is the first *Truth* we meet with in our orderly Philosophizing; because the Existence of our own *Soul*, which we gather from our *Cogitation*, is more known to us than the Existence of any other Beings. For the *Thinking Mind*, which is understood by this word, *I*, doth know it self before it knows any thing else; and the word, *am*, which imports the first Person, is before the word, *is*, which is only applied to the Third Person. For

who is there who doth not first *Think* of himself as of a particular Being, before he doth of *Man* in general? It is natural to our *Mind* to think of a *singular* Being, which is proposed to our *Sense* or *Understanding*, before we think of a Being taken in *general*; and therefore this Proposition may well be esteem'd by us as a first Principle, since from this proof of our own Existence, we confirm the Existence of *God*, of *Material things*, and in a word, of all *Creatures* whatsoever.

I am not ignorant, that this is commonly taken to be the first Principle, *It is impossible for the same thing to be, and not to be*. But I see not how this Proposition can be of any use to us, in order to the attaining of Knowledge, since it doth not prove the Existence of any thing, and doth seem to suppose that something is, which ought to have been prov'd before. For it presupposeth its Division into *Ens* and *Non Ens*, or *Being* and *Not Being*; whence that Maxim is derived, *Every thing either is, or is not*. But our Principle, *I who think do exist*, presupposeth nothing at all; and when all other things are liable to be question'd and doubted of, yet it is absolutely impossible, that *I who think* should not be something; that is, that I should not exist.

There be Three Species of *Cogitation*; *Pure Intellection*, *Imagination* and *Sense*: For by these Three Modes or Ways the *Mind* of *Man* perceives or thinks.

The *Mind* is said to *Understand* purely, when by her self alone, and by turning into her self, she perceives a thing only by attending to the *Idea* she hath of it; or when she perceives a thing, whereof there is no Footstep in the *Brain*. And in this manner the *Soul* apprehends things *Spiritual* and *Universal*, *Common Notions*, the *Idea* of *Perfection*, and finally, all her own *Thoughts*: Or likewise when it understands *Material things*, *Extension* with its *Affections*: For it is with the *Understanding* alone, that a *Perfect Circle*, a *Thousand Corner'd Figure*, &c. can be conceived.

The *Mind* is said to *Imagine*, when it applies its Knowing faculty to the *Body*, as intimately present with it; or when it applies it self not to the *Thing* it self, which is present to the outward *Sense*, but to the *Phantasm* impress'd by it in the *Brain*: As when it perceives a *Figure*, a *Circle*, a *Triangle*, the *Stars*, a *Machin*, &c. And these Perceptions are called *Imaginations*, because the *Mind* by representing these *Things* to her self, doth form *Images* in the *Brain*; and forasmuch as it cannot frame any *Images* of *Spiritual things*, it follows that neither can they be imagined.

Lastly, The *Mind* of *Man*, by *Sense*, only perceives sensible Objects and things that are more obvious, as being present, and affecting the outward Organs. Thus it perceives *Steeple*s, *Fields*, *Animals*, &c. and these Perceptions are called *Sensations*.

'Tis by these Three ways only that the *Mind* of *Man* perceives things: For whatsoever is represented to it is either *Spiritual* or *Material*; if *Spiritual*, it can be apprehended by the *Understanding* only; if *Material*, then it is present or absent: If absent, the *Soul* represents it to it self by the *Imagination*; if present, it perceives it by Impressions made on the *Senses*. So that there are only Three ways by which the *Soul* apprehends any thing,

IV.
It is im-
possible for
the same
thing to be,
and not to be,
is not
the first
Principle.

V.
Three Spe-
cies or
kinds of
Perception.

VI.
Pure Intel-
lect.

VII.
Imagina-
tion.

VIII.
Sense.

thing, viz. by Pure Intellect, Imagination, or Sense.

IX. Hence it is manifest, that the Object of the Understanding is of a larger extent, than the Object of Imagination: For by our Understanding we do not only conceive the Nature of Spirits and of a Body in general; but also the Proprieties of particular Bodies; which cannot be discovered by the Senses, nor by the Imagination neither, being only perceivable by the Intellect. Thus, tho' the Understanding perceives that, the Diagonal Line of a Square, is to that degree incommensurable with the side of it, that tho' a Division into infinite parts should be supposed, yet we could never come to a Particle that might be the common Measure of them both: Nevertheless this Truth can never be reached by the Imagination, but rather seems repugnant to it: Because we can imagin nothing but some particular determinate Body, the Species whereof is impress'd on our Brain, as hath been said.

X. And tho' the Mind doth sometimes contemplate Material and Corporeal things; yet it doth never admit any Corporeal Species, which are only received into the Brain, on which the Mind doth not depend in its Operations. For in order to Pure Intellection, we have no need of the Brain, but only for Sensation or Imagination. Whence it follows, that we can Understand many things which we cannot Imagin. I perceive by the Light of Nature that GOD exists, tho' I cannot represent him to my self by any Image. So likewise I have a clear perception of a Chiliagon or Thousand Corner'd Body; which yet I cannot imagin, that is, presentially behold its Thousand Sides; because the vast number of them confounds the Imagination. Now that I have a clear Perception of a Thousand Corner'd Body appears, because I can demonstrate many things concerning it, as that all its Angles together are equal to 1996 right Angles; which could not be, if I had only a confus'd Conception of it.

XI. It is to be noted, that no Error can be in the Understanding or Imagination, as long as they continue purely in the Contemplation of things: For if the Idea we have of those things it represents be conform with them, it is true; and if it disagree, then is it no representation of them. Moreover, since Falshood or Error consists in our attributing to a Subject what doth not belong to it, or denying of it what doth, it is plain that since the Understanding or Imagination do neither affirm nor deny, there can be no Falshood in them. Neither doth it contradict this, that the Understanding sometimes apprehends a False thing, as when it conceives a Non Entity, or Repugnant terms; as when the Mind conceives one that is no Physician, to be a Physician; in which Conception there can be no Falshood, because it truly conceives a Physician, tho' it apply that Conception to a wrong Subject.

XII. Wherefore all danger of Mistake is from our Will, when we give our Assent or Dissent to any thing we have not clearly perceived. Yet is not this to be understood, as if we did wilfully embrace Error; but because we do not restrain our Will sufficiently, but reach it forth to those things we do not perfectly understand. For it is another thing to be willing to be deceived, and to assent to those

things in which Falshood is involved. And tho' few be so careless of themselves, as to desire to fall into Error, yet many are willing to give their Assent to those things in which Error is hid. For all Assent belongs to the Will, and is to be numbred amongst its Perceptions. For we see it is in our Power, tho' we perceive a thing, yet to suspend our Judgment, which restraint is the Determination of the Will; as likewise are Desire, Aversion, Dubitation, &c. For to the Understanding only belong Pure Intellection, Imagination, and Sensation.

XIII. Since therefore FALSHOOD consists in the hasty Consent of the Will, it can by no means be imputed to the Intellect, because Error is not to be found in Perceptions, neither is it any way intelligible. Yet forasmuch as the Understanding commonly hath imperfect and confused Conceptions of things, it may be said to be an occasional Cause of our Errors. For as, our Bodily Sight frequently leads us into Mistake, by representing Objects confusedly and imperfectly to us; so the Understanding having for the most part only a confused Perception of things, is a cause of the Wills falling into many Errors, by assenting to those things which are obscurely perceived by the Understanding.

CHAP. IV.

Of the Five Universals, or Predicables.

I. WE are to suppose in the first Place, that there are Beings that have some reality in the Nature of things; and whose Attributes belong to them, whether the Understanding think so or not. Such are all Substances, and all Attributes or Modes, which denominate or vary them. Others again derive all the Being they have from the Intellect, on the operation whereof they so depend, as to vanish away upon its Cessation; as are all those which are called *Entia Rationis* (Entities of Reason) in the Schools.

II. In the Second place we are to suppose, that nothing else is to be understood by the word Universal, than that which agrees or is attributable to many things; as the word Substance, which agrees to Body and Spirit. Wherefore all Universals are in our Understanding, and to speak properly, are only Modes of Thinking. For seeing all Natural things are Singular and distinct from each other, these Universals can have no Unity, but what our Understanding gives them. By Example, Two Lines if separately consider'd, cannot be said to agree in the Notion of a Line; because in the Conception of the one, is included the Negation of the other; wherefore to the end they may agree, we must first frame an Idea, which may serve us for the conceiving of all Lines that are like one another. Thus we put some Common Name upon all those things which are represented by an Idea, which Name is commonly called an Universal. And thus that famous Number of Universals, which hath rack'd so many Brains, may easily be salv'd.

III. For Example, When we consider Substance extended in Length, Breadth and Depth, we frame an Idea of it, and call it the Idea of a Body, which afterwards is of use to us for the representing of all Bodies to our Mind. But seeing that many of them are distinguish'd by Species, as into Living Bodies and

Sometimes the Understanding is the cause of Error.

There is a twofold Genus of Beings or Entities.

Universals are only Modes of Thinking.

How Universals are formed.

and Inanimate, the Universal Name with relation to them is called *GENUS*. And since many of them differ only in Number; as *two Lines* of the same Magnitude, or *two Spherical Bodies*, we conceive an *Universal Idea*, which may represent all Lines that are measur'd by the same length, and all round Bodies contain'd within the same Surface; which *Idea*, with reference to them, as Numerically distinct, is called *SPECIES*, which is the Second *Universal*.

IV.
An Universal is considered as a Whole, or as a Part.

Whence it follows, that one and the same *Universal*, with respect to the self-same Inferiour, may be considered either as a *Part*, or a *Whole*: For both the *Genus* in respect of the *Species*, and the *Species* in respect of the *Individuals*, is called a *WHOLE*: Thus *Animal* contains a Man and Beast. *Universals* also may be look'd upon as *Parts* of their Inferiours; so a *Man* is conceived as consisting of his *Genus* and *Difference*, that is, of an *Animal* and *Rationality*.

V.
The Original of Difference and Proprium.

Neither hath the *Universal*, called *Difference*, any other Original; for when we consider that there is some difference between those things which we understand to be under the same *Genus*, or *Species*; we apprehend this variety under some common Notion, which we afterwards attribute to every *Difference*: As *Streightness* or *Rectitude*, whereby a *Line* is distinguish'd from one that is of another Figure. *Roundedness*, whereby a *Globe* is distinguish'd from an *Angular Body*, &c. The *Predicable Proprium* is made, when we abstract one Notion from those that are peculiar to Things, and to which alone it agrees, and to no other: As *Partition* or *Divisibility*, and *Mobility* to a *Body*.

VI.
How the Universal called Accident is framed.

Accident is framed by us, when after we have considered that many things may happen to, or be taken from Things, without the destruction of their Nature, we conceive the *Idea* of an *Entity* separable from them, which we call *Accident*: Which Name we make use of for the conceiving of all those things, which fortuitously happen to Things. And this is sufficient for the Explication of the Nature of *Universals*, especially to those who do not love to spend their time in vain Questions, or to confound the Notions of Things with fruitless Disputations.

VII.
The Partition of an Universal into five Species is a complete Division.

Now that this Division of an *Universal*, is *Adaequate*; that is, that there are neither more nor less Members of them than these Five, appears thus: The *Idea* which we frame in our Mind, and make use of to conceive many Things, either represents many Things distinguish'd by *Species*, and then it is *Genus*; or only Numerically distinct, and then it is *Species*; or it represents the Diversity, whereby many *Singulars* differ amongst themselves, and from other things, and then it is *Difference*; or the Property which belongs to them alone, and then it is *Proprium*; or some Contingency separable from their Essence, and this makes *Accident*, or the first and last *Predicable*.

VIII.
What Predicables are.

These Five *Universals* are otherwise called *Prædicabilia*, *Predicables*, because they are *Modes of conceiving Universal Notions*, which are affirmed of many things Truly, Properly, Naturally and Immediately. They are said to be *Modes of Conceiving*, to intimate to us, that *Predicables* are Second Notions. For *Genus* is nothing in it self, but only with respect to those things with which it

is compared; neither is there any *Species*, but with respect to the *Genus* to which it is subjected: neither can *Difference*, *Property* or *Accident* be conceived, but with relation to the Subjects they belong to.

CHAP. V.

Universals singly examin'd, as to their Nature, Properties, and Use.

THOUGH I have in the foregoing Chapter sufficiently made out, that there are Five *Universals* or *Predicables*, and that they are distinguish'd from each other by their Differences; yet I suppose it may be of use to give a more particular Explication of them, and set down how they are predicated of their Inferiours.

I.
It is of use to take a review of these Universals.

GENUS deserves the first place amongst *Universals*, both in order and dignity; for from it, as from their Head, the other Members depend, and are maintain'd, and upon its ceasing perish and vanish. *Genus* therefore is an *Universal*, which is predicated of many things distinct by *Species*, in the Question *What it is*. As *Substance* is a *Genus* in respect of *Substance* extended, called a *Body*, and *Substance Thinking*, which is called a *Mind* or *Spirit*; and a *Quadrilateral* or *Square Figure*, is the *Genus* with respect to a *Parallelogram* and a *Trapezium*. To be predicated in the Question *What*, is when enquiry is made into the Nature of any thing, what it is. Thus when I enquire what a *Body*, or what a *Mind* is, the Answer is properly made by their *Genus*, viz. *Substance*; and herein it differs from *Difference*, *Property*, and *Accident*: For tho' *Difference* be predicated by *What*, or *Essentially*, of those things whose *Difference* it is; yet it is not simply predicated *to*, but with the addition of *Quale*; which denotes the Form or Quality of a thing; and *Property* and *Accidents* are only predicated in *Quale*.

II.
Genus takes the first place amongst Universals.

Wherefore in the foregoing Definition of *Genus*, *What it is* to be distinguish'd by *Species*, is to differ *Essentially*, so as that some *Essential* part is found in the one and not in the other. Thus *Man* and *Beast* are said to be distinct by *Species*, because a *Mind* or *Rational Soul* is found in *Man*, which is not to be met with in a *Beast*.

III.
What it is to be distinguish'd by Species, is to differ essentially, so as that some Essential part is found in the one and not in the other.

Genus is twofold: One, the most General or Highest, which hath no *Genus* above it: As a *Corporeal Being* amongst extended Substances; and an *Intellectual* or *Thinking Being*, amongst those that are endow'd with *Knowledge* and *Understanding*.

IV.
Genus is twofold, one suprem or the highest.

The other *Genus* is called *Subaltern*, which intervenes betwixt the highest *Genus* and the lowest *Species*; or which with respect to the things above it is a *Species*, and with respect to the Inferiour is call'd *Genus*. Thus *Living Thing*, if it be referr'd to *Body*, under which it is sort'd, is called a *Species*; but if to *Animal*, it is a *Genus*. And consequently, *Body* is a remote *Genus* of *Animal*, but *Living Thing* the nearest *Genus*.

V.
The other, Subaltern.

The Second *Universal* is *SPECIES*, which is predicated of many, only Numerically distinct in the Question, *What a thing is*. By the last part of this Definition of *Species* we find it agrees with *Genus*, in that they both of them answer to the Question, *What a Thing is*: As when I ask, *What is Peter?* I answer aright by saying, that he is a *Man*.

VI.
What Species is, and how it is divided.

Species

VII.
The Division
of
Species.

Species is twofold: The one called the Lowest or most Special; the other, Middlemost or Intervening: The latter of which, tho' with respect to the Genus under which it stands, it be called *Species*; yet with respect to the Inferiours, of which it is predicated, it is a *Genus*: So Animal which is the *Species* of Living Thing, is the *Genus* in respect of Man or Beast.

VIII.
What the
most Special
or Lowest
Species is.

The most Special, or the Lowest Species, is that which is immediately predicated of *Individuals*: As Man of *Charles* and *James*; a Circle of all particular *Circles*: Which is therefore call'd the most Special or Lowest Species, because it hath no Species under it, but only *Individuals*. Wherefore also it is commonly defined, that which is predicated of Many, differing only Numerically in the Question which asks, What a thing is?

IX.
How many
ways Difference
is
to be under-
stood.

The Third Universal is *DIFFERENCE*, which may be variously considered: First, forasmuch as it is the Constituent of *Species*; and then it may be defined to be *that whereby the Species doth exceed, or is more worthy than the Genus*: As Man exceeds an Animal or Sensitive Creature by *Rationality*. Secondly, As it is something *Predicable*, and so it is commonly defined to be an *Universal*, which is predicated of many different in *Specie*, in the Question, *Quale quid, or of what kind of Essence a thing is*. And this Definition agrees only to the intermediate *Difference*. Thirdly, Inasmuch as it divides the Genus into differing Species; thus *Rational* and *Irrational* divide *Animal*, and constitute two Species, *viz. Man* and *Beast*. So the Equality of the Sides constitutes an *Equilateral Triangle*, and determines the Idea of a *Triangle*, which before was common to a certain *Species*. Fourthly, As it is an *Essential* part of the whole Compound, and so it makes a part of its *Essence*, and belongs to its Definition: Wherein it differs from a *Property* and *Accident*, as being an *Actual* part of the things to which it is attributed.

X.
The Species
includes
more than
the Genus.

For in every Species there must necessarily be something more than there is in the Genus; for otherwise there would be no distinction at all between the several Species, seeing they all agree in the Genus; and therefore if there be any diversity betwixt them, the same is to be fetch'd from the *Difference*. For Example; The *Body* and *Mind* are two Species of Substance, and therefore it is necessary that in the Idea of *Body* there should be somewhat more found than in the Idea of *Substance*; and the same must be said of the Idea of the *Mind*. Now whereas the first thing we meet with in a *Body*, is *Extension*; and in the *Mind* or *Soul*, *Cogitation*; we may say, that *Extension* is the *Difference* of *Bodies*, and *Cogitation* the *Difference* of the *Soul*: Or in other words, That a *Body* is a Substance extended, and the *Soul* or *Mind* a Thinking Substance. Wherefore *Difference*, as it is the Third *Predicable*, may be thus defined: *That which is predicated of the Species, and of the things contained under it by the Question, Quale quid, or of what kind of Essence the thing is*.

XI.
The four-
fold divi-
sion of
Property.
The first
Mode.

PROPRIUM is taken in a Fourfold Sense or Acception: First, *That which agrees alone to the Species, but not to all the Species*; that is, to all the *Individuals* resorting under it. As, to *Cure by Art*, is attributable to Man alone, but not to all his *Individuals*.

Secondly, *That which agrees to the whole Species, but not to it alone*. As it agrees to Man to walk on two Feet; for the same may be also said of other *Animals* yet not of all. So *Divisibility* is the Property of *Extension*, because every extended Being can be divided; tho' *Duration* and *Number* be also divisible.

Thirdly, *That which is attributable only and to the whole Species, yet not always, but only at a certain time*: As to grow grey-headed is peculiar to a Man; not in his Childhood or Youth, but in his Old Age: For if it happens otherwise, it is look'd upon as a *Prodigy*.

Fourthly, *That which is attributable only, and to the whole Species, and at all times*: As it is the property only of a Circle, of every Circle, and at all times, that all the Lines drawn from the Circumference to the Center, are equal. And this last sort of Property is that which constitutes the Fourth *Universal*; the other three Modes being rather referable to *Accidents*; because they do not agree necessarily, nor always, nor to the whole Species, but contingently, sometimes and in part only. And thus *Proprium* in this last Sense may be defined, *that which is predicated of many things by themselves, and necessarily, yet not essentially*. I have added the word *Necessarily*, because Property doth so agree with a thing, that it cannot so much as by Thought be separated from it; forasmuch as it is a necessary consequent of its *Essence*, and is convertible with it. Thus it is the essential Property of a *Triangle*, that two of its Sides taken together, are bigger than the third, and that its three Angles be equal to two right ones; because these do necessarily agree to a *Triangle*, inasmuch as it is a Figure bounded by three right Lines.

In the last place, we call all that *Accident*, which is not *Substance*, neither doth necessarily agree to it, but doth only contingently follow the same; or is that *which without the destruction of the Subject may be present or absent*. As *Roundness*, *Hardness*, &c. are common *Accidents* with respect to a *Body*, as *Sorrow* and *Fear* are *Accidents* with regard to the *Soul* or *Mind*. An *Accident* is twofold; *Separable*, which may easily be separated from the Subject in which it is conceived to be, as *sleep*, from Man; or *Inseparable*, which cannot be separated from the thing in which it is by the force of Nature, as *whiteness* from a *Swan*, *blackness* from a *Blackamore*: Tho' they may be abstracted by *Cogitation*; for we can conceive a *Swan* without *whiteness*, and a *Man* without *blackness*. Wherein, as hath been said, it is distinguish'd from a *Propriety*, which cannot so much as by *Cogitation* be removed from its Subject.

When an *Accident* is said to be present or absent without the destruction of the Subject; this is not to be understood in a *Conjunct* Sense, as if the same *Accident* could at the same time be present and absent from the same Subject: But in a *Divided* Sense, so as that the *Accident* which is now present may be absent, and on the contrary. For it is a *Contradiction* that two opposit *Predicats*, should at the same time be predicated of the same thing, though they may at divers times.

To the end that the Order of the Highest Genus, and those that are Subaltern, as also of the Species, may be the better known, it will be of use to subjoyn here a Series of *Universals*, by which we may be

and Species

be able to descend from the highest Genus, to wit, Substance, to *Individuals*; and remount back again from the *Individuals* to the highest Genus. For by this Scheme the Mind is much enlightned, and avoids that Confusion, which otherwise is apt to arise in the Defining, Dividing, and Enumerating of things. A Substance, Corporeal, Intellectual.

A Body, Void of Life. Living, A Living Thing, Void of Sense.

Sensitive, An Animal, or Sensitive Creature, Void of Mind.

Endued with Mind, A Man, Plato.

This, Another, Plato.

XVII. Which Series may be made after an Analytical way.

The Words which follow from Substance to Man, are called *Intervening Genus's*, and those on the Right and Left are the *Differences*, which are said to be placed in an Indirect Line. From those words which are disposed in a Direct Line, we make the Series in a twofold manner; either by Analysis or Division descending, beginning from the Highest Genus, which is Substance, and distributing it, and all other the Genus's that resort under it, into their Species by their Difference, till we come to the Individuals. As if one should divide Substance into Corporeal and Intellectual; and then a Body into Living and Void of Life; and then a Living Body, into that which is Sensitive and devoid of Sense; and a Sensitive Creature or Animal, into that which hath a Mind, and which is destitute of it; and at last, an Animal endued with a Mind, viz. a Man into Plato, Socrates, Aristotle, &c.

XVIII. Or by a Synthetical way.

The other is by way of Synthesis ascending, beginning from the Individuals, and from them mounting to the Subaltern Genus's, and lastly to the Highest Genus, viz. Substance. As when considering all particular Men, and finding them all to agree in the Nature of Man, we place Man as the Species above the Individuals. Then comparing Man with Animals or Sensitive Creatures, and finding in them the common Nature of Animals, we place Animal as the Genus above Man. Afterwards making a Comparison of an Animal with Plants, and finding them to agree in the common Attribute of Life or Living; we put Living above Animal: And then if we compare Living things with those that are destitute of Life, we shall find the common Notion in them both; and therefore place Body above Living. Lastly, If we compare Bodily things with Angels and the Mind of Man, we shall find the common Notion of Substance in them both; and therefore will place Substance as the Genus above Body, by which means, Substance will be left the Highest Genus.

XIX. What an Individual is, and its division.

A Singular or Individual is opposed to an Universal, because it cannot be common to many Inferiour; as *this Man, this Sword*. It is twofold, either Indeterminate, which without difference may signifie this or the other Individual; as *a certain Man, a certain Woman*: Or Signate and Determinate; as *Julius Caesar*, which is called Determinate by its Signification; or by Demonstration, as when a common Word is determined by a demonstrative Particle; as *this Colledge, this Court or Yard*: Or by Circumlocution; as the Son of Socrates, or the Son of the Blessed

Virgin for Christ: And are therefore called by Aristotle, *Individuals, Singulars*, and Things differing in Number, because they cannot be divided as the fore said *Universals*; and because we in a manner point at them, as if we were counting of them one by one, when we say *this, that, the other, &c.*

Hence it appears what is the Use of *Universals*, and how far they conduce to the Knowledge of Things: For seeing that a thing considered under an Universal Notion, is a thing, as it is apprehended common to many Inferiours, or as it is predicable of many; we shall find that the consideration of *Universals*, is a great help to clear and distinct Perception, the obtaining of which is chiefly aimed at by all that is handled in this LOGICK. For by the help of these *Universals*, or *Prædicables*, we are enabled to discern the Attributes which constitute the Essence of a thing, from those which are Consequent to, and to know which are the *Properties* and *Accidents* of every thing: As for Example, it belongs to the Constitution of Socrates his Nature, that he be a Man, a Sensitive Creature, and Rational: Which Three in their Universality are distinguish'd; Man being the Species, Sensitive Creature or Animal the Genus, and Rational the Difference. Which tho' in Socrates they are all one and the same, yet are distinguish'd according to our Mode of Thinking. But the Faculty of Laughing, or Laughter it self, is consider'd as a consequent of Socrates his Essence, who is already constituted a Man, by his being an Animal and Rational. And the Faculty of Laughing is the Property of Man, but the Act of Laughing an Accident.

The Consideration of *Universals* is also of great Use to the more clear Perception of Things, whether they be Singular or Common. Of Singulars, whilst we enquire under what Species they are placed, what Genus's they have, ascending by degrees to the Highest. Of Common or *Universals*, when we examine what Differences they have, and what Species they contain, descending in this manner to the very Individuals. Thus by ascending, I know Socrates to be a Man, a Man to be an Animal, an Animal to be a Substance: And again by descending, I learn that Substance is either Intellectual or Corporeal; the Intellectual to be either Infinite, as God; or Finite, and that either without a Body, viz. an Angel, or joyned to a Body, as Man's Soul; under which Species the Mind of Socrates, as a Singular or Individual doth resort.

The Second thing which follows from the Consideration of *Universals* is, that there are two ways of framing General Idea's, the one by Aggregation, the other by Abstraction. The Mind forms an Universal Idea by Aggregation, when it joyns many Singular Idea's of a like Nature together into one complex Universal Idea, which is called Genus. Thus making a Congeries or Collection of all Brute Beasts, as of Lions, Horses, Bears, &c. we find them all to agree in the Idea of a Brute Beast, which we therefore call the Genus of them.

Again, we may form an Universal Idea by Abstraction, when we attribute the Attributes which constitute the Essence of a thing into several ranks or degrees, as if they were so many Parts. For tho' the Idea's of Singular things do agree in some one thing, yet they differ in more; wherefore when the Mind doth abstractedly and severally consider

XX.

The first Use of Universals.

XXI.

The second Use of Universals.

XXII.

Our Mind frames a general Idea two several ways, the one by joyning or aggregating.

XXIII.

The other by Abstraction.

things, in which many like Idea's are found, neglecting those wherein they differ: this abstract Consideration is called an *Universal Idea* or *Genus*. As for Example, If I take from *John*, *Peter*, *James*, all the Particularities that determine them, as that the one is a *Physician*, the other *old*, the third *young*, &c. and that I only consider them as being all *endued with Sense and Reason*: This affords me the General Idea of a *Man*, forasmuch as thereby not any particular Man is represented to me; but Man in Common, or the Nature of Man as such.

C H A P. VI.

Of Substance, and its Affections or Modes.

I.
The difference of our Perceptions.

The difference of *Perceptions* or *Idea's* is taken either from the Things themselves which we understand, or from our different ways of Perceiving them, or lastly proceeds from the *Words* or *Signs* whereby we express our Notions. Now whatsoever is understood by us, is either conceived as a *Thing*, or *Substance*, existing by it self; or as the Attribute of a *Thing*, or *Mode* of *Substance*; or as something made up of a *Thing* and *Mode*; or a *Modified thing*; or lastly, *Propositions of Eternal Truth* residing in our Mind.

II.
What Substance is.

Substance is a thing, which does not need any other Substance for its existence; that is, which hath an *Essence* really distinct and separable from others. By this means is a *Substance* distinguish'd from an *Accident*, which is not really distinct from a *Substance*, nor can exist separate from it: Nay, an *Accident* cannot be clearly and distinctly conceived without a *Substance*, because its very *Essence* is to be in another; and nothing can be clearly and distinctly conceived without its *Essence*.

III.
Substance as known by its Attributes.

Tho' it be sufficient for the Explication of the Notion of *Substance*, to say, that it is a thing which exists independently of another; yet we cannot distinctly understand it, but by means of some Attributes that belong to it; and the more of these are found in any Substance, the clearer it is said to be known. For the *Attributes* or *Properties* of Things are, as it were, certain *Forms* that actuate them, and distinguish them from others: For we more easily know a *Rational Soul*, by conceiving it as a *Thinking Substance*, than as a thing *Existing*; because if it thinks, it must of necessity exist. So in like manner we have a clearer knowledge of a *Body*, by considering it as a *Thing* extended, than only as a thing existing, as is evident to him that considers it.

IV.
A Substance created is either Created or Uncreated.

SUBSTANCE is twofold; *Created* or *Uncreated*. *Created* is a Substance independent of all other things whatsoever, as *GOD*. A *Created Substance* is that, which tho' it do not stand in need of another Substance for its Existence; yet wants the *Divine Concurrence*, without which it cannot exist; and therefore is not an absolute, but only a dependent *Being*.

V.
Created Substance is divided into Intellectual and Corporeal.

Of *Created Beings*, some are *Intellectual*, others *Corporeal*. An *Intellectual Being* is a *Thinking Substance*, as the *Mind* of *Man*: A *Corporeal* is a Substance extended in *Length*, *Breadth* and *Depth*; or is the immediate Subject of *Local Extension*, and of all *Modes* that presuppose *Extension*, as *Magnitude*, *Motion*, *Figure*, *Position*, and all other such like, which cannot be conceived without *Local Ex-*

tenfion, as the foundation of them. And to the *Mind* or *Soul* belong all *Acts* or *Modes* of *Cogitation*, as to *Understand*, *Imagin*, *Feel*, and whatever else agrees in the universal Notion of *Cogitation*.

Whence follows that there are only two *Genus's* VI. or General Heads of Things, viz. of *Material* and *Intellectual*, or *Cogitative*: All others being reducible to these as *Modes* or *Affections*; now what these are, and how related to their Subjects, we shall next proceed to explain.

There be many Attributes we may conceive in every thing; some of which constitute the Nature and *Essence* of a thing, and distinguish it from all others; as *Extension*, which constitutes a *Bodily Substance*, and distinguishes it from a *Cogitative Being*: Others again presuppose the Nature constituted, and do only diversly affect or vary the same, as *Volition* doth the *Mind*, and *Figure* the *Body*; and these are called the *Modes* of *Substances*. Because tho' they affect or vary the Substance, yet it may be conceived without them, tho' they themselves cannot be understood but as inherent in some Subject; for herein properly the Nature of a *Modus* doth consist, that it cannot be conceived without including the Conception of the thing whose *Mode* it is. Thus I clearly perceive that a *Body* is an extended Substance, without *Motion* or *Figure*: But it is impossible for me to conceive *Motion* or *Figure*, except it be in an extended Being. So likewise I clearly perceive the *Mind* to be a *Thinking Substance*, without *Imagination* or *Sense*, because tho' these were absent it would be *Cogitative* notwithstanding: But *Sense* and *Imagination* cannot be conceived, but in a *Cogitative Being*.

Wherefore a Modern Philosopher calls a *Mode*, VIII. the *Appendix of a Being*; because it cannot exist without the thing whose *Appendix* it is. Which we are to observe in opposition of those, who suppose that the *Modes* of things differ not at all from *Real Accidents*; forasmuch as these, according to them, may be conceived separate from their Subjects, and can exist so by the *Divine Power*. Whereas *Modes* can neither be separated from their Subjects, nor conceived without them; for otherwise they would be *Substances*, whose Nature it is to be Things subsisting.

Substance therefore is a thing that subsists by it self, and is the Subject of all the Attributes that are conceived to be in it.

A *Mode* is that Attribute or Quality, which is conceived to be in the Substance it self, which terminates it to be such like. And this *Mode* is called by us an *Imperfect Being*, because it belongs to the Nature of it, that it cannot be by it self, and without some Substance in which it is; and whose *Being*, as the Schools express it, is nothing else but *Inbeing*; so that it is a contradiction for a *Mode* to be, and not to be or exist in a Substance. Wherefore neither can a *Modus* pass from the Substance, which is its Subject, and does support and uphold it, into another; for this would argue it not to have been dependent on the Substance wherein it was before, which implies a Contradiction.

Of *Modes*, some are *Internal*, others *External*. *Internal* are such as are conceived to be in the very Substances, as *Figure*, *Motion*, *Rest*, &c. *External* are such as depend on other Things, and are not in

in the Substances themselves, as to be *Beloved, Desired, &c.* which are Modes depending on the Action of another; and the Expressions we make use of to signify the said Modes, are called *Extrinsic Denominations*; because they only express the Modes under which things are conceived.

XII.
What a
thing Mo-
dified is.

A *Thing modified* is the Substance it self, which is determined by a *Modus*.

XIII.
These Three
things ex-
plain'd by
an Exam-
ple.

As when I consider a *Body*, the Idea I have of it represents to me a *Body* or *Substance*, because I apprehend it as a *Self-subsisting* thing, which needs no outward thing to its existence: But when I consider that *Body Round* or *Square*, the Idea which I have of its *Roundness* or *Squareness* represents nothing else to me, but a certain *Mode of Existence*, which I find cannot naturally exist without a *Body*, to which the *Roundness* or *Squareness* belongs: And lastly, when I joyn the *Mode* with the *Thing*, that Idea represents to me the *Thing modified*.

XIV.

Modes
make no
Compound
of the
thing whose
Modes they
are.

From what hath been said, it follows, First, That the *Modes* of *Things* are no hindrance to their *Simplicity*: For *Extension*, by Example, with the various *Modes* of *Extension*, as *Figure, Motion, &c.* is not a *Compound*, but a *Simple* thing. For that is said to be a *Compound* which contains two, or more *Attributes*, whereof the one may be distinctly perceived without the other; and since the *Modes* cannot be considered without the *Substance* in which they are, it cannot be said that they make a *Compound* of it. A *Simple Being* is that in which one only *Attribute* is found; whence it follows, that that *Subject* in which *Extension* alone, with its various *Modes* is understood, is a *Simple Being*; and that wherein we only apprehend the *Cognitive Faculty*, with the various *Modes* of *Willing, Understanding, Imagining*, is likewise a *Simple Being*: But that which comprehends both *Extension* and *Cognition* is a *Compound*, viz. *Man*, who consists of *Soul* and *Body*.

XV.

Substance
is some-
times con-
sider'd as
a Mode.

Secondly, Hence it follows that a *Substance* may sometimes be applicable to another in manner of a *Mode*. So *Cloaths*, when a *Man* is said to be *Clothed*, must only be called a *Modus*, notwithstanding that they are *Substances*; because *Man* is then considered as a *Subject*, to which *Cloaths* are added in the manner of a *Mode*.

XVI.

The distin-
ction be-
twixt an
Attribute,
a Mode,
and a
Quality.

Thirdly, From what hath been said we may gather, that we may conceive some difference between an *Attribute*, a *Mode*, and a *Quality*: As that an *Attribute* is that which is generally conceived to be in a *Substance*; so he who thinks of the *Duration* of the *Sun* doth contemplate an *Attribute*, under which the *Sun* is understood, forasmuch as it continues in its being. And thus all *Attributes* are then distinctly understood by us, when we take care to affix no *Conception* of a *Substance* to them. We call that a *Mode*, which any way affects or varies a thing: So *Wax* is diversified by *Figures*. And a *Quality* is that whence a *Substance* is denominat'd *Talis*, or such like, as *Wax*, that is, *soft, cold, white, &c.* so *softness* is the *Quality* of *Wax*.

XVII.

With what
Names Sub-
stances and
Modes are
express'd.

The *Names* whereby we express *Substances*, are called *Nouns Substantive*, as *Mind, Body, &c.* The *Names* which express *Things modified*, and which primarily and directly signify *Substances*, and Modes indirectly, are also *Nouns Substantives*: As the *Earth, the Sun, &c.* But *Words* that primarily and directly, but confusedly signify *Substances*, and

which indirectly, but distinctly express *Modes*, are called *Nouns Adjective*; such are *round, white, just, &c.*

The other things which fall under our Knowledge, are *Propositions of Eternal Truth*; which are not understood as *Existing* things, or the *Modes* of things; but as *Eternal Truths* abiding in our Understanding: As, *That which is, whilst it is, cannot be nothing: I am, because I think: What is once done, cannot be undone*; which are therefore called *Common Notions*, because they are so simple and clear, that they cannot but be perceived by all Men. Neither must it be look'd upon as an *Absurdity*, that we call any thing *Eternal* and *Immutable*, besides *GOD*; because we do not speak here of *Existing* things, but only of *Notions* and *Axioms* which are in our *Mind*.

XVIII.
What Pro-
positions of
Eternal
Truth are.

Neither doth it hinder the *Truth* of these *Propositions*, that all of them do not appear equally evident to all Men; for the Reason of this is, because they are not all conceived after the same manner, and consequently not with the same Evidence. Not that I think the *Minds* of Men to be divers, and that the *Knowing Faculty* of one Man is larger than another's; but because probably these *Common Notions* may thwart the prejudicate *Opinions* of some Men, who therefore cannot so easily apprehend them; tho' others that are free from such *Prejudices*, do perceive them with the greatest Evidence.

XIX.
The same
are per-
ceived by
all, except
their Pre-
judices
hinder
them.

CHAP. VII.

Of the Common Attributes of Substance.

Forasmuch as *Things* are understood by their *Attributes*, and are the more distinctly conceived by us, by how much the more *Attributes* we apprehend in them; I thought it needful to reckon up all the *Attributes* of *Substance*, that so nothing that belongs to the *Nature* of it, may be concealed from us.

I.
The Attri-
butes by
which
Substance
is known.

The *Attributes* of *Substances* are either *Primary* or *Antecedent*, or *Originate* and following from the *Antecedent*. The *Primary* are those which are considered by us as certain *Principles* (not *Effective*, but *Formal*) as well of the *Substance*, as chiefly of all the rest of the *Attributes*; seeing that when they are supposed, the others immediately follow, and are therefore called the *Principles of Being* or *Substance*; and they are two, viz. *Essence* and *Existence*.

II.
There are
two Genus's
of Attri-
butes.

ESSENCE is the first Radical and inward Principle, Foundation, and Root of *Substance*, and all its *Properties* and *Operations*: For it is the *Entity* or *Form* whereby it is something, and that which it is. Thus a *Spiritual* thing, suppose an *Angel*, by means of its *Essence* is not only a thing, but also such a Being that is *Intelligent*, and not a *Material Substance*. And so likewise a *Body* hath not only from its *Essence* that it is something, but also that it is *Material*, and void of *Understanding*. And therefore the *Essence* is by the Schools called, the *Metaphysical Form*, because it is the *Chief* thing whereby a *Thing* is distinguish'd from all others. When I say, the *Chief Thing*, it is not to be understood as if there were something in *Substance*, besides *Essence*, but only with respect to our *Perception*, which commonly proceeds by *Parts*, tho' the *Thing* it self be *Simple*, without any *Composition*.

III.
Essence.

Having

IV.
Existence.

Having inform'd our selves *what the Thing is* that is in question, the next enquiry is, *Whether it be*; that is, whether such a thing be to be found in the Nature of Things, to which the foresaid Essence doth belong; and to this Question *Existence* belongs, by which a *Being* is said to subsist, or by which the Essence is constituted in the Nature of Things: And therefore is called *Actus Entitativus*, an *Entitative Act*; as if Existence were only understood by the operation or acting of Things. A Being in *Potentia*, or a *Possible Being*, is oppos'd to a Being in *Act*. So a *Lilly* in Summer is said to be an *Existent Being*; but in Winter, a *Possible Being*, *Ens in Potentia*; because tho' it do not then exist, yet it is not repugnant to it, to be or exist in Time. Whence it appears that *Essence* and *Existence* cannot be separated from each other, since (to speak properly) they are nothing else but two different Modes of Thinking: For we do otherwise conceive the Essence of a thing, when we abstract Existence or Non-existence from it, than when we conceive it Existing. So when we apprehend *Possible* and *Actual Being* in one and the same thing, by different Conceptions, we do indeed conceive the thing as in a twofold State, but do not therefore divide it into more things. Thus the *Sun* that now appears in our Heaven, is the same that has continued from the beginning. Therefore the Power by which things that are not yet, are said to be *Possible*, is called *Objective*; forasmuch as such Things are the Objects of some Cause, by which they may be produced in due place and time.

V.
Attributes
Originate,
or proceeding
from
others.

From these two first or primary Attributes, other Attributes follow, which are likewise common to all *Substance*, and are called *Originate*, or *Consequent*; and are either *Absolute*, which belong to the Substance considered by it self; or *Respective*, which agree to the Thing with reference to others. The Absolute Attributes are *Duration*, *Unity*, *Truth*, *Goodness*, &c.

VI.
Duration.

Duration is nothing else but an Attribute, under which the Existence of Created Things is understood, with reference to their perseverance in their Actual existence. So that *Duration* agrees to all *Existent Beings*, as long as they exist. With respect to *Duration*, some things are called *Corruptible*, and others *Incorruptible*. A *Corruptible Being*, is that which can perish and cease to be, or lose the Existence it hath: As the *Individuals* of every Species, which may be corrupted and changed into another Species. An *Incorruptible Being* is that, whose Existence cannot be destroyed, and is either Simply such, as *GOD*, who is *subject to no Change or Corruptibility*; or in certain respects only, which is preserved by the *Power of GOD*, so as to suffer no diminution or increase. So *Matter* which continues one and the same in the World, is said to be *Incorruptible*; tho' second or singular *Matters*, as to their Forms, be subject to Generation and Corruption.

VII.
Unity.

Another Attribute of Substance is *Unity*, by which every thing is said to be Undivided in it self. Thus those things are said to be *One*, which are of the same Subaltern Genus or Species, because they are considered by us under one and the same Notion, and for that we make use only of one Conception, to represent all those Things to our Minds which agree together: And this Unity is called

Universal. But *Singular Unity* appertains to those Things, which without the Operation of our Mind are undivided, or to whose Nature it is repugnant to be divided into more *Entities*; whereby is verified that Common Saying of the *Philosophers*, That *whatsoever is, is Singular*; because that which is not *One*, cannot be esteemed to be. Some Things again are *One* by themselves, and others by Accident: Things *One by themselves* are such as have an Undivided Nature, whether they be Simple or Compound. For the multitude of Parts is no hindrance of *Unity*, so the Parts, which constitute a Third thing, be but closely joyn'd together. For *Man* is said to be *One* by himself, notwithstanding that he consists of Parts of a different Nature, and separable from each other. Whereas those things are called *One by Accident*, which consist of disjoyn'd Parts, and between which there is only a very slight Union. So an *Army* is called *One Body* by Accident, because it consists of a great number of Men joyn'd by an Imperfect Union.

In Substance we also consider *Truth*, which is commonly called *Metaphysical*, or *Transcendental*; and is nothing else but the correspondence of the Name with the Thing signified by it. For in this Sense the Nature and Essence of every thing may be said to be *True*. So that to enquire into the Nature of any Thing, is the same as to search what a Thing is, and of what kind it is: And to find out *Truth* is nothing else, but to comprehend whether a Thing be, and of what Nature a Thing is. Wherefore, since it is not in the Power of Creatures, to change the Natures and Essences of Things, no more than they can *Eternal Truths*, it follows, that there is nothing oppos'd to *Transcendental Truth*. For tho' *Justice* be oppos'd to *Injustice*, *Truth* to *Falshood*, and *true Gold* to *false Gold*; yet the Things which are oppos'd to *true Vertues* have no Nature, neither have we any positive Idea of them: For that which is opposite to *true Gold* hath no Essence at all; and in like manner, that which is contrary to *True Faith*, or *True Fortitude*.

To *Metaphysical Truth* are referred not only those Things which have, or may have an Existence without the Intellect, as all *Natural Beings*; but also whatsoever is *Positive*, and consequently hath an Essence or Nature, tho' it have no Existence without the Intellect. For not only those Things which are the Object of our Senses, as *Heaven*, *Earth*, the *Sea*, *Sound*, *Colour*, &c. do enjoy a *True* and proper Essence; but *Fortitude*, *Justice*, a *right Line*, a *Triangle*, *Cause*, *Effect*, and in a word, whatsoever we apprehend as *Positive*, or in the manner of an *Entity*. For we say, *True Justice*, a *True Triangle*, &c. because their Nature is *True*, and because we can demonstrate many things of them; as of *Justice*, that it gives to every thing its own: Of a *Triangle*, that its three Angles are equal to two Right ones.

Goodness follows *Truth*, and is likewise reckoned amongst the General Affections of Substance: For if a Thing have that Essence which it ought to have; that is, if it be *True*, it must of necessity be *Good* also. And therefore we frequently confound the Denominations of *True* and *Good*; as when we call a *True Syllogism*, *Good*, because the thing which agrees with our Understanding, cannot disagree with our Will, in case the Will be right, and

and that it be carried towards it after clear Perception. Thus GOD, after he had Created the World, and all things contain'd in it, he declar'd them all to be *very good*, because they agreed with the Idea's he had of them, and therefore were such as he would have them to be. Wherefore *Aristotle* defines *Good* to be that *which all do desire*, forasmuch as nothing is desired, but what agrees with the Will. As there are many degrees of Truth, so also of Goodness, whilst we account some more excellent than others, which we more especially do, when we measure the Goodness of any thing from its Actions, or the strength and force of its Acting. Thus we say, that the *Mind* excels the *Body*, and the *Fire* the rest of the Elements.

XI. Thus much for the Absolute Attributes of Substance; we proceed now to the *Relative*, which agree to a Substance as related to another, and not as considered in it self. Now *Relation* is nothing else, but a Mode of our Understanding, comparing one thing with others, because of some Properties or Acts that are found in them: So a *Father* is Related to his *Son*, because he hath begot him; and the *Son* to his *Father*, as being begotten of him. If we consider a *Father* and *Son* Materially, without their Relation, we shall call them *Subject*; but if we consider them with respect to one another, we shall call the one the *Relate*, and the other the *Correlate*; because as the *Father* is related to the *Son* by *Paternity* or *Fatherhood*; so is the *Son* to the *Father* by *Filiation* or *Sonship*. Upon which account it is that *Relatives* are said to be or exist *Naturally both together*; because you cannot suppose the one, without supposing the other: For supposing a *Husband*, you must suppose a *Wife* too; and supposing a *Master*, he must have a *Servant*.

XII. *Relation* is manifold; viz. a Relation of *Origination*, of *Negation*, of *Affirmation*, of *Comparison*, of *Composition*, of *Accession*, and of *Substitution*.

Relation of Origination is, between a Principle and that which proceeds from it; as between the *Day-break* and a *Day*, a *Point* and a *Line*, a *Substance* and its *Properties*.

Relation of Negation, is between distinct Things, or between Things going before, and those that follow after. The former of these is called a Relation of *Distinction*, the latter a Relation of *Order*.

Relation of Affirmation is, whereby one thing is affirmed of another.

Relation of Composition, is between the Whole and the Parts, the Simple and the Compound, the Perfect and Imperfect.

Relation of Accession, is between the Subject and the Adjunct.

Lastly, *Relation of Substitution*, is that which intervenes betwixt the Sign, and that which is signified by it; the Measure and the thing Measured; the Image and the Original.

XIII. As one Substance is related to another, so likewise it is opposed to another: As when we so conceive of Two things, as that they cannot consist together. So *white* and *black Things* are said to be opposed, and these are called *Contraries*, because the Essence of one is different from the Essence of the other; yet not wholly and altogether, but because

there is something in the Nature of one of them, which is not in the other. Those things are called *Disparate*, or *Disagreeing*, when one thing is opposed to many after one and the same manner: As *white* is opposed to *green*, *yellow*, *blew*; because *white* is not only opposite to *green*, but also to *yellow* and *blew*, and all Middle Colours. But when one *Opposite* altogether denies the other; as a *God*, *No God*; they are commonly called *Contradictories*. And this is the greatest of all Oppositions, forasmuch as it denies every where, and always. But if it deny the same only in a certain Subject, as *Sight* in a Sensitive Creature, then they are called *Privative Opposites*: Because by Privation is understood the absence of some Entity in a Subject capable of receiving it, as *Blindness in the Eye*, which is capable of *Sight*.

Order is another Attribute of Substance, consisting in first and last, or former and latter. It is various, according to the diversity of *Place*, *Time*, *Dignity*, *Knowledge*, and *Perfection*, which we conceive to be in things. *Order of Knowledge*, is taken from the Things themselves; and by this *Causes* are before *Effects*; *Simple Terms* are more known than *Complex*. *Order of Dignity*, is fetch'd from the Essence of things; thus the *Mind* is more worthy than the *Body*: Or from *Accidents*; thus a *King* is more worthy than his *Subjects*, a *Master* than his *Servants*. A Thing is said to be before another in *Nature*, whose Essence doth precede the other; or from whose Existence the latter is not infer'd, but on the contrary: So an *Animal*, or a *Sensitive Creature*, is said to be by Nature before *Man*; because tho' an *Animal* exist, it doth not therefore follow that a *Man* exists; yet when a *Man* exists, it follows that an *Animal* exists also.

CHAP. VIII.

How the Name of Substance agrees to GOD and the Creatures.

FOR the better clearing of this Difficulty, we are to suppose with *Logicians*, that a Name may after divers manners be communicated to a Thing. First, *Univocally*, when it agrees to many Things for the same Reason; as when the name *Triangle* is given to all Figures contained within three Lines. *Equivocally*, when we call many things that are essentially distinct by the same common Name, for divers Reasons: As when in Latin we use the Name *Gallus*, to signify a *Cock* and a *Frenchman*; or when we use the word *Parabola*, to signify an *Allegory*, or *Similitude*, and a *Geometrical Figure*. *Analogically*, as when we give the same Name to many Things; but to one Principally, and to the other Secondarily: As when we say that an *Animal*, a *Pulse*, and *Physick* are *Healthful*; for *Health* principally and chiefly agrees only to an *Animal*, to the *Pulse* as it is a sign of it, and to *Medicine*, because it procures it. Having briefly observed these things,

I say, First, that the Name of Substance doth not agree to God and the Creatures *Univocally*. Which I prove thus: Different Participation destroys *Univocation*; but God and the Creatures participate the Name of Substance after a different manner therefore. The Minor is proved, because God is a Substance Independent of any other; but all other Creatures are Substances dependent of Him:

Him: GOD alone is He, who needs no other to his Existence; but all *Creatures* stand in need of the Divine Concurrence for their Existence, neither can they without it be conceived to exist in the Nature of Things.

III.
The same
expressed in
other
words.

Or otherwise thus: The Idea of *Substance*, is the conception of a Being subsisting of, or by it self; but there is no *Creature* so exists by it self, as to be sufficient for its own Existence, or so Powerful, as to be able to keep and preserve it self: Wherefore the Name of *Substance* cannot *Univocally* agree to God and the *Creature*.

IV.
A Being
from him-
self and
from ano-
ther, are
absolute
Differences.

And if with more attention we consider the Matter, we shall find that God and the *Creature* do not agree in the Idea of any Genus whatsoever; and that the word *Being*, *Ens*, which is commonly by *Logicians* attributed to God and the *Creature*, is perfectly *Equivocal*; and that the *Equivocation* is not more plain in the word *Dog*, when attributed to a *Constellation* in Heaven, and to a *Beast* on Earth; or in the Latin word *Jus*, which signifies *Law* or *Right*, and *Broth*, than in the word *Ens*, or *Being*, when given to a Being which is of it self, and to one that is from another and altogether dependent. For to exist of ones self, or to be made by another are meer *Differences*, which do not admit any common Genus; and as God is distinguished by the former, so are all *Creatures* by the latter: God being a purely Self-existent and Independent Being, and the *Creatures* purely dependent Beings, and existing from another.

V.
God is
above
Substance.

Wherefore *S. Denys* calls GOD *Super-substantia*, and *Super-ens*, (*Above-substance*, and *Above-entity*) because he is raised above all Substances, and separate and distinct from all other Things whatsoever. Accordingly he that would make a true Scheme of the *Predicaments*, must set down *Ens à se*, or a Self-existent Being by it self, and distinct from the Series of other things; and afterwards *Ens ab alio*, or a Being that is from another, as the Original of *Differences*, placing at the Right hand of it *Intellectual*, and on the Left *Corporeal*, and then put the next Division of Things. Because the Name of *Entity*, or *Being*, only agrees with the Being, which is of it self, and can only *Equivocally* be assigned to *Creatures*, that have their Being from another.

VI.
An Obje-
ction an-
swer'd.

If any one say, that the word *Substance* agrees in common both to God and the *Creatures*, and that all the Inequality that is found in them doth arise only from the *Differences* of it? I answer, That this is not true, forasmuch as Dependency is involved in the Essential Conception of a *Creature*. Now it is required to the Nature of *Univocal Words*, that they be equally communicable to all, and not to one Primarily and to the other Secondarily, or with dependance on the First.

VII.
The Idea
or Notion
of Sub-
stance is
Univocally
competent
to *Crea-
tures*.

I say in the Second place, that the word *Substance* doth *Univocally* agree to all *Creatures*. For all *Creatures* are conceived under this Common Notion, that all of them stand in need of the Divine Concurrence for their Existence. Now that Name which is attributed to many for the same Reason, and equally participated by them, is *Univocal*; therefore the Name of *Substance* is distinctly understood to be Common to all *Creatures*, according to the property of *Univocals*.

VIII. Having thus explained these Things, I think I

have with one and the same labour explained *Why the* all *Metaphysicks*, concerning *Entity* and its *Affe- Genealogy* ctions; yet that no Body may complain, that of Things the same has been left out in this Institution, seeing is here the consideration of it doth indeed belong to *Lo- annexed.* gick, I shall subjoyn here such a Genealogy of Things and Modes, by means of which the Student of Philosophy may, as it were at one View, contemplate the whole University of Things.

The Fifth Rule of Truth.

It avails much to the clear and distinct Perception of Truth, to retain in ones Mind an accurate Genealogy of Things and Modes, that with one cast of an Eye we may be able to take a view of the whole Universe of Things, beginning from the most General, and ending in the most Special.

The Reason is, because this will be a great Help towards the thorough Knowledge of Things, as pointing us to what *Tribe* they do belong, what Affinity they have with some, and what Difference from other Things; neither will it be of less Use to us in the defining, describing, and distributing of Things. And to the end you may have a short Compendium at hand, of all those Things in general, which fall under the Perception of our Mind, and consequently also of those *Ideas*, which the Mind forms to it self, whilst it beholds them: Behold I here furnish you with such a Genealogy, as contains all and every one of the Genera of Things and Modes, each in its proper order and degree.

The Genealogy of Things and Modes.

Whatsoever falls under the clear and distinct Perception of our Mind, is somewhat.

And that Somewhat, } A Thing, A
is either } or,
The Mode of a Thing, B

I. A Thing, (or an Entity or Substance, for they are Synonymous) is something which hath an Essence and Existence distinct from all other Things. Essence is the Natural and Invariable Constitution of the Thing, by which it is that which it is. Existence is a Consequent upon the Essence of a Thing, by which it now actually is, or is the Essence it self now existing in the University of Things. The Consideration whereof belongs to *ὀνολογία*, by some called *First Philosophy*, and by others *Metaphysicks*, which treats of Things Universally, and therefore also is called *Catbolick*, or *Universal*.

A Thing or Substance in Gene- } Thinking, a
ral, is twofold } or,
Extended, b
1. Infinite, as GOD, whence is Natu-
ral Theology.
Thinking, or } 2. Finite, as } an Angel, whence is
a Mind is } the Mind } Angelography.
either } of } a Man; whence Psy-
chology.

This part of the Genealogy of a Thinking Substance is handled in *Noëtica*, that is, *Pneumatica*, as others term it; the Parts whereof I have just now mentioned.

A Thing Extended, or a Body, is twofold.

I. An Element; that is, a Principle whence other mix'd Bodies have their Original, and into which they are resolved again at last. Which again is Threefold.

1. Subtil

1. *Subtil Matter*, which constitutes the *Stars*.
2. The *Heavenly Globular Matter*, whence the *Light and Heavens* are.

3. The *Grosser Particles of Matter*, whence are the *Planets and Comets*.

II. *Elementatum*, or *Principiatum*; that is, all those things that have their Original from the *Elements*.

And these are again *Twofold*:

I. *Without Life*, or *Concrete*; which branch themselves into,

1. *Simple Concretes*; as the *Heaven*, which consists of the *Globuli* of the *Second Element*; and the *Stars*, of the *Matter of the First Element*.

2. *More Compound Concretes*.

1. Those on high, as *Planets, Comets, &c.*

2. Those beneath, as *Meteors*, as *Vapours, Wind, Rain, Snow, Hail, Thunder, Earth*, and things consisting of these: As *Fossils*; that is, *Common Minerals, Metals, and Stones* (*Precious*).

II. *Living*, or *Animated*.

1. *Without Sense*, or *Vegetable*, as *Herbs*, as all kind of *Plants*, whether *Shrubs*, or *Trees*.

2. *Endowed with Sense*; 1. *Rational*, as *Man*, as an *Animal*, 2. *Irrational*, as a *Beast*.

This Part of the *Genealogy*, concerning *Extended Substance*, or *Body*, is unfolded in *Physiology*, or *Natural Philosophy*, which is also called *Somatica*.

II. The *Mode*, (that is, the *Attribute, Affection, Accident*) of a *Thing*, is somewhat of an *Entity* or *Being*; that is and exists by the assistance of another thing.

These are *Twofold*, *General*, and *Special*.

I. *General*; Such are the *Modes or Attributes* of all *Things* in *General*, commonly called *Transcendentals*: As,

1. *Unity*; by which every thing is always one and the same, and *Undivided*. *Multitude* is a *Collection of Unities*.

2. *Truth*; by which a thing is conformable to its *Idea*. *Falsity* contrariwise.

3. *Goodness*; whereby it is fit for *Use*.

4. *Perfection*; whereby it is whole and entire, and hath whatsoever it ought to have.

5. *Locality*; whereby it is every where, as *God*; or somewhere, as all other *Things* besides *God*.

6. *Duration*; whereby a *Thing* continues in its *Existence* either always, or for a certain time: *Eternity*.

As *Time* is divided into *Present*, *Past*, and *Future*.

These *Things* are explained in the *First Philosophy*, or *Metaphysics*, which treats of *Things*, and of their *Modes and Affections* *Universally*.

II. *Special*; Such are the *Modes or Attributes* of *Things* in *Specie*.

(1) For the *Division of Things*: As,

I. The *Modes*, that is, the *Attributes of a Thing* *Cogitating*: As, *Intellection*, and *Volition*.
As, *Power to act of it self*, *Autonomous*.

2. The *Modes or Attributes of a Thing extended*, or *Corporeal*:

1. *Quantity*, or *Magnitude*; which *Mathematicks*, or *Positica* treats of.

2. *Figure*; or the different *Termination of Magnitude*, handled in that Part of *Mathematicks*, which is called *Geometry*.

3. *Situation*; or the certain *Position* of a *Thing* in *Place and Space*.

4. The *Quiet or Rest* of the *Parts* of any *Thing*.

5. *Local Motion*, or the *Variation of Situation*, whence proceed *Active and Passive Qualities*; as *Rarity and Density, Fluidity and Hardness, Heat and Cold, Moisture and Dryness*, and the rest; which are treated of in *Natural Philosophy*.

(2.) From the *Thinking*, result the following *Conjunctions* and *Modes and Affections* of a thing *Extended*:

1. The *Appetite of Hunger and Thirst*.

Internal; *Phantasy* or *Imagination* and *Memory*.

2. The *Senses*; External; *Seeing, Hearing, Smelling, Tasting, and Feeling*.

And their *Affections*, as *Waking and Sleep*.

3. The *Affections or Passions*; as *Love, Joy, Hatred, Sorrow, Hope, Fear*, and the several kinds of them, which are also handled in *Physiology*.

Hence we may gather in the first place, that *Philosophy* considered in all its *Parts*, is nothing else but a *Scientificall Explication* of this or a like *Genealogy*. For a *Philosopher* pretends nothing else, and is content with this alone to understand the *Natures of Things*, to know their *Forms, Differences, Affections*, and that from the nearest *Causes*, if the *Mind* can reach them: Now this will hardly be obtained by him who is not well vers'd in the *Genealogy of Things*.

In the next place, That this *Genealogy* is abundantly sufficient to supply the place of the *Common Categories and Predicaments of the Aristoteleans*.

By *Predicaments and Categories*, they understand such a *Series and Disposition of Things*; in which the *Superiour* is always *predicated*, that is, affirmed *Univocally*, that is, according to *Name and Thing*, of its *Inferiours* in the same *Predicamental Line*. Taking this for granted, as a thing known to all *Men*, there are many things which I cannot approve of in the *Constitution* of those *Predicaments*.

First, That they divide *Ens* into *Substance* and *Accident* without any *Reason*: Forasmuch as an *Accident* is no *Entity*, as appears from the foregoing *Definition of Ens (A. I.)*; but rather is something belonging to an *Ens*, according to (B. II.)

Secondly, In that they constitute *Nine* *supream Genera of Accidents*, which they thus reckon up; *Quantity, Quality, Action, Passion, Relation, When, Where, Situation, and Habit*.

Where first they mistake in this, that they make those to be the *Supream Genera*, and distinct too, which truly are not so; as *Quantity*, and *Quality*: For the greatest part of *Physical or Natural Qualities* arise from *Quantity, Figure and Motion*. Secondly, *Relation* doth not in the least belong to the *Genealogy of Things*, because it is

X.
The Scope of a Philosopher is, to know the Natures of Things.

XI.
What the Peripateticks understand by Predicaments.

XII.
What is to be disproved of in the Categorical Series.

no absolute thing, but only an Affection framed by Reason, viz. an Opposition, with or under some respect. Thirdly, *Action* and *Passion* in Bodies are reducible to Motion, whose Species or Modes they are. Fourthly, The Division of *Ens* into Substance and Accident, invented by *Aristotle*, deviates from the Rules of a good Division; because the Parts of it are not opposite. Fifthly and lastly, If any true Attributes of Things be found amongst them, the same may be more fitly deduced from our Genealogy: As for Example, *Quantity* belongs to the first Mode of an Extended Being; *Quality*, if it be Mental, to the Modes of Intellection and Volition; if it be Physical, or Corporeal, to the Fifth Mode of an Extended Being, or to others: *When* and *Where*, to Duration and Place, which are the General Attributes of Things: *Situation* is the Mode of an Extended thing, or the respect of one Body to others, considered as near to it: And *Habit* is the Common Adjunct or Accident of some Things; as of a *Human Body*, or some other.

CHAP. IX.

Of the Whole and Parts, Causes and Effects, Subject and Adjunct.

I. **H**AVING thus Explained the General Attributes of Things, as far as is sufficient for the Knowing of Things in General; if any one further desire to Know Things more distinctly and evidently in *Species*, and particularly, he must consider the thing either as a *Whole*, consisting of *Parts*; or as an *Effect*, produced by *Causes*; or as a *Subject*, furnish'd with various *Attributes*. For this will be a great furtherance to attain a clear and distinct Knowledge, that is, Perception of any Thing.

II. It follows therefore, that we explain the Notions of a *Whole* and its *Parts*, of a *Cause* and its *Effects*, of *Subject* and *Adjunct*; because from these Notions, the Idea of every thing is absolutely and to the Life express'd in the Mind of him that Thinks.

III. We call that a *WHOLE*, which consists of many things joyned together, or which hath *Parts*, into which it may be divided: For a thing which wants *Parts*, is improperly called a *Whole*. Wherefore the *Aristotelians* are in a Mistake when they say, that the Mind of Man is *Whole in the whole Body*, and *Whole in every Part*; because the *Mind* being an Intellectual Substance, is without *Parts*, and after an Indivisible manner in the Body: Wherefore also an Immaterial Substance cannot be said to be *Whole*, save only Negatively, inasmuch as it doth not admit of *Parts*, or Division. A *Whole* is threefold, *Essential*, *Integral*, and *Universal*. An *Essential Whole*, is that which consists of *Parts*, whereof the one is in the other, as are *Matter* and *Form*: Thus Man consists of *Soul* and *Body*. An *Integral Whole*, is that which hath *Parts* without each other; as a Man's *Body* consists of *Head*, *Hands*, &c. An *Universal Whole*, is any Genus with respect to its Species; as *Animal* respecting Man and Beast: Or a *Species*, referring to its Individuals; as *Man* to *Socrates* and *Plato*.

IV. We call that a *PART*, which together with its *Copart*, or with many of them, doth constitute a *Whole*; as the *Soul* and *Body* make a Man. A *Part* is either *Principal*, without which a *Whole* cannot consist; as is the *Head* in a *Human Body*:

Or *Less Principal*, which when sever'd doth only maim the whole, but not destroy it.

V. Tho' the Word *CAUSE* be of it self sufficiently known to all, and therefore the Explication of it seems superfluous; yet is it commonly defined, *That from whose Being something else follows: Or, That which of it self, influenceth something different from it self.* Accordingly, *GOD* the Father is the Principle, but not the Cause of the Son; for the Son is another Person from the Father, but not another Thing, that is, not of another or different Nature.

VI. There are Five Genera or kinds of Causes, viz. the *Material*, the *Formal*, the *Efficient*, the *Exemplary*, and the *Final*.

VII. The *Material Cause*, is that out of which things are made or formed; as *Wax* is the Matter of which *Tapers* are made; *Pewter*, the Matter of which *Pots* are made; *Gold*, of which *Guinea's* are made. So that whatsoever is agreeing or disagreeing with the Matter, the same also agrees or disagrees with the Things that are made out of it.

VIII. The *Formal* is that which Constitutes another thing, and distinguisheth it from all other; as the *Soul* is the Form of Man: But whether the Forms of other things be *Physical Entities*, as they talk in the Schools, or only a disposition of *Parts*, shall be discoursed in the General Part of *Physiology*, where this Point shall be distinctly handled. Both these Causes are called *Internal*, because they abide in those Things whose Essence they do constitute.

IX. The *Efficient*, or *Effecting Cause*, is that which produceth another thing; and the same is manifest.

X. *Total* or *Adequate*, which alone doth produce the Effect, excluding other Causes of the same Rank; as *God* creating *Adam*, whom he produc'd without the Concourse of any Other.

XI. But a Father and Mother, or Male and Female, are said to be *Partial Causes*, with respect to the Child they generate; because they need each others assistance, and can do nothing solitarily.

XII. The *Sun* is the *Proper Cause* of *Light*; but only an *Accidental Cause* of the Death of a Man, who is kill'd by too great Heat; because the bad Constitution of his Body, was the occasion of his being hurt by the Heat of the *Sun*.

XIII. A Father is the *Near Cause* of his Son; but a Grandfather the *Remote*.

XIV. A Mother is the *Effective*, or *Productive Cause* of her Son, because she effects a thing which before did not exist.

XV. A Nurse is only the *Conserving Cause*, because she only effects the Continuation of its Existence, and lends her assistance that it may continue in that Existence, which it hath received from its Parents.

XVI. A Father is an *Univocal Cause*, with respect to his Children; because they are of the same Nature with him.

XVII. But *GOD* is only an *Equivocal Cause*, with respect to his Creatures; because they are of a different Nature from His, and in Dignity inferior to him.

XVIII. An Artificer is called the *Principal Cause* of his Work, because he acts voluntarily; but *Instruments*, because they are managed by him, as means subvenient to the performing of his Work, are only said to be *Instrumental Causes*: Because tho' there be some kind of Power to work in the Instruments, as

in the *Hatchet* to Cleave, in the *Knife* to Cut; yet can they not produce the said Effects, except they be actuated and applied by another Cause. And therefore are called *Passive*, because they receive their acting Power from the *Principal Cause*.

XIX.

An Universal Cause.

The *Water* that springs up into divers Water-Works in the Gardens of Princes, and which moves variety of Machins, is the *Universal Cause* of their Motion, because it is indifferently forced up into them all: But the Artificial disposition and figure of the Pipes is the *Particular Cause*, which determines the *Universal*, and restrains it to some particular effect.

XX.

A Natural Cause.

Bodily Things, when they act, are said to be *Natural Causes*, because they produce an Effect from a Natural Propensity or Necessity, without any fore-knowing Knowledge; as the *Sun*, *Fire*, and the like: But *Man* is the *Intellectual Cause* of those things which he effects by his Understanding and Will.

XXI.

A Voluntary Cause.

A Man that *Walketh* is a *Free Cause*, because he acts spontaneously, and not by force: But a *Fire* burning Wood is a *Necessary Cause*, because where those things are present which are required to its action, as *dry Wood*, application of them to the *Fire*, and *Ventilation* or *Blowing*, it cannot but burn them, neither can it exert any other Action instead of it.

XXII.

A Proper Cause, and without which.

The *Sun*, whilst it enlightens a Chamber, is the *Proper Cause* of the *Light* that is in it: But the opening of a *Window*, or taking down of the *Shutters*, is only a Cause *sine qua non*, or without which such an Effect would not follow; which Cause is also called the *Condition*, without which a Thing cannot be.

XXIII.

A Physical and Moral Cause.

A *Fire* that burns Houses, is the *Physical Cause* of that Burning or Consuming, because the *Fire* properly and of its own Nature burns: But a Man who sets Houses on Fire, or that exhorts or commands others to do so, is only a *Moral Cause* of this Burning; because he hath only Morally contributed to that effect, viz. by Exhorting or Commanding. Thus the *Serpent*, or the *Devil*, was the *Moral Cause* of the Fall of our First Parents.

XXIV.

An Exemplary Cause.

The Form which a Man proposeth to himself in going about to make a Work, is called the *Exemplary Cause*; as the Form which an Architect conceives of a *House* he is about to build; and generally whatsoever can be a Cause of an *Objective Entity*, or of forming any other Image. So he who is the Object of the Eyes or Mind of the *Painter*, is the *Exemplary Cause* of his own Effigies or Likeness.

XXV.

What the Final Cause is.

The *Final Cause*, is the *End* for which any thing is; as when a Man applies himself to his Studies, in order to the attaining of *Learning*: And therefore the *End* is commonly defined, the Cause for whose sake any thing is.

XXVI.

A Primary End.

An *End* is twofold, either *Primary*, which is principally intended; as the *End* of a *Knife* is to Cut; of a *Garment*, to cover the *Body*, and to shield it from the Injuries of the *Weather*.

XXVII.

A Secondary End.

A less *Principal* or *Secondary End* is, which moves one only in a less degree, and is only considered as something Accessory. Thus the *Secondary End* of a *Garment* is to adorn the *Body*.

XXVIII.

The End for whose sake.

That which a Man intends to do, or to obtain, is called the *End for whose sake*: So *Learning* is the End of Studies, *Health* the End of the Phy-

sician's Art, as being that which it intends to procure.

He for whom any thing is desired, is called the *End for whom*: So *Man* is the *End for whom* of *Medicine*; because it designs to procure *Health* to him. To form ones *Reason* aright, or to direct the *Understanding* into the knowledge of all things whatsoever, is the *Adequate End* of *Logick*: But to direct the *Understanding* in Natural things, or in the exercise of Vertuous Actions, is the *Inadequate* or *Partial End* of *Logick*.

Whence we may gather, that the *Material Cause* is that out of which Things are made; the *Formal*, by which; the *Efficient*, from which; the *Exemplary*, according to which; and the *Final*, for which things are made.

Whence it follows, that the *Effect* or *Thing caused*, which depends on the *Cause*, and by virtue whereof it is, is Fivefold; viz. an *Effect*, which proceeds from the *Efficient Cause*: The *Thing designed*, or the *Means* ordained to the *End*: The *Thing materiaterd*, or which consists of the *Matter*, and is made of it: The *Thing formed*, or constituted by the *Form*. To these you may add the *Thing exemplated*, in respect of the *Exemplar* according to which it is made.

That is called a *Subject* to which something is adjoyned, or to which something accrues besides its Essence: So *Cloaths* are put on the *Body*; the *Soul* of *Man* is joyned to his *Body*; *Writing* is applied to *Paper*.

A *Subject of Inherence*, is that into which something is received: So a *Spunge* is said to be the *Matter* into which the *Water* is received: The *Outside* of the *Wall* is that which receives the *plaster* or *whiting* in it. A *Subject of Adherence* is, which receives another thing upon it self, or to it self, as a *Hand* that puts on a *Glove*. A *Subject Containing*, is that which comprehends any thing within it self; as a *Vessel* doth *Water*, or the *Sheath* doth the *Sword*: Because by *Subject* nothing else is understood here, than that to which something is joyned besides its Essence; or to which something supervenes after its production and constitution.

A *Subject* is sometimes taken for an *Object*; as when we say, to *subject* a thing to the Eyes of any one; that is, to propose a thing to any ones Faculties, that he may act about or in it. So the *Object of Hearing* is a *Sound*, the *Object of Seeing*, *Colour*.

We call that an *Adjunct*, which we consider to be in a thing besides its Essence, as something added, accruing or hapning to it, whether the same bring along with it some proper Reality; as *Fire* in the Pores of hot *Iron*, the *Soul* in the *Body*: Or whether it be nothing else but a *Mode* of Substance; as *Love* or *Science* in the *Mind*; *Motion*, *Figure*, *Rest*, *Situation* in a *Body*.

An *Accidental Adjunct* is predicated of its Subject in *Concrete*, and not *Abstractedly*. That is called a *Concrete Adjunct*, which denotes the *Accidental form* together with the *Subject*; as *White*, *Learned*, *Great*, &c. An *Abstract Adjunct* is that which signifies only the *Accidental* or *Modal form*; as *Whiteness*, *Learning*, *Greatness*. Wherefore an *Adjunct* is predicated of its Subject in the *Concrete*; *Snow* is *white*, *Socrates* is *Learned*, *Great*: But by no means in the *Abstract*; as *Socrates* is *Whiteness*, *Learning*, *Greatness*.

To these things thus at large explained, we will subjoin this Rule.

The Sixth Rule of Truth.

XXXVII.
The Sixth
Rule of
Truth.

The Idea or Perception of every thing is by so much the more clear and perfect, by how much the more Parts, Causes and Adjuncts of the thing it doth represent.

For from the Parts we have a view of the Whole; from the Causes, what is contained in the Effects; from the Adjuncts, as so many Complements and Ornaments, we perceive the Nature of the Subject, and its Qualifications, especially from its proper inborn Qualities.

CHAP. X.

Concerning the Distinctions, whence the Nature and Difference of Ideas is deduced.

I.
What is
the Consent
and Dissent
of Things.

For a more clear understanding of what follows, we will premise something concerning the Consent and Dissent of Things. Now those things seem to me to Consent, which agree in Common Attributes and Logical Notions; and those to Dissent, which do more or less disagree in the same.

The Seventh Rule of Truth.

II.
The Se-
venth Rule
of Truth.

Those Things are to be looked upon as Agreeing, which agree in some common Idea or Reason, or whereof the one is included in the Idea of the other; and they are said to disagree or to be diverse, which are the Objects of Different Ideas, and are apprehended after a diverse manner; or the one whereof is not included in the Idea of the other.

III.
Which
Things
agree, and
which do
disagree.

For those things only do Agree, which have the same Genus or Species, or Parts, or Causes, or Effects, or Subjects, or Adjuncts; or Agree upon some other account: Whereas those which Disagree in the same, are diverse and dissentaneous. But those things do most of all Disagree, which are separated from each other by opposite Differences.

IV.
What di-
stinction is,
and how
manifest.

Wherefore Distinction in Common is nothing else, than the Diversity we find, between many things. Which Diversity, to speak properly, is only to be found between Existing Beings: For that which is not, cannot be said to be distinguish'd. Distinction is threefold, Real, Modal, and Distinction of Reason.

V.
What a
Real Di-
stinction
is.

Real Distinction is that which is found between two or more compleat Beings or Substances; as between the Soul and Body, which we know to be distinguish'd from each other, because we can distinctly know the one without the other: For we can have no more evident sign of Real Distinction than this, that we do distinctly and clearly understand the one without the other. I said in the Definition, that Distinction is a Diversity, and not a Division; because Distinction doth not take away Union, but Identity only. For tho' the Soul be never so closely United to the Body, yet it continues, no less distinct from the same, than if it were actually separated from it: For it is sufficient to make a distinction, if the Things may be separated and preserved apart from each other.

VI.
The Soul
and Body
are Really
Distinct, as
Compleat
Beings.

But you'll object against the Instance of Soul and Body, that they are only Incompleat Substances, and therefore cannot be really distinguish'd? I answer, by distinguishing the Minor, I grant that the Soul and Body are Incompleat Substances, if they be re-

ferr'd to the Compound which they constitute. But if by calling them Incompleat Substances, you mean that they cannot subsist by themselves: This I deny.

For when we say a Compleat thing, we understand nothing else, than a Substance furnished with such Attributes and Forms, as from which we gather it to be a Substance: For it is plain, that we do not know a Substance immediately, but from its Attributes, which because they must be in something or other, therefore we call the Subject in which they are, Substance. In which respect the Soul and Body are said to be Compleat Beings. The same may be said of all the Parts that concur to the making up of a Whole. Thus an Eye, for Example, is an Incompleat Substance, if it be compar'd with the Body, whose Part it is: But is said to be a Compleat Entity, when considered by itself alone; and in like manner the Soul and the Body are Incompleat Substances in reference to the Whole Man; but Compleat, when they are considered with those Attributes by which we know them to be Substances.

A Modal Distinction is that which is found between a Mode and its Subject, whose Mode it is: So Figure is distinguish'd from a Bodily Substance; the Act of Imagining or Willing from an Immaterial Substance, or the Soul. For those things we know to be Modally distinguish'd, where the one of them may be conceived to exist without the other, but not on the contrary: As we can easily understand a Corporeal Substance without Motion and Figure, but can by no means conceive Motion or Figure without a Body.

There is another Modal Distinction between two Modes of one and the same Substance: As between the Figure and Motion of one and the same Body, or between a Substance and the Mode of another Substance: But this latter is rather to be called a Real Distinction, than Modal; forasmuch as That Mode may be clearly understood without the other, and hath no dependance on the Substance, as not affecting or modifying it.

A Distinction of Reason, is that which is found between a Substance and some one of its Essential Attributes: Thus Quantity doth not differ from a Bodily Substance, but only by a Distinction of Reason; as Cogitation from the Mind. The Sign of this Distinction is, when we cannot have a distinct Idea of the Thing, if we remove from it that Attribute, as appears in the Examples alledged. And so likewise, two Attributes of the same Substance are distinguish'd only by Reason, if they be such as: that the Notion of the one cannot be clearly conceived without the other; as Justice and Mercy in GOD. And these are said to be Formally distinguish'd, because their Formal Ideas or Definitions are distinct or diverse.

From what hath been said, we may gather first, What the Ideas are which we have of Things; viz. that they are Conceptions, or rather the Things themselves conceived and understood by the Mind; by which Intellection things are said to be Objectively in the Intellect. So that we can express nothing in Words, if we understand what we say, but there must be an Idea in us of what we express by our Words: Tho' the Idea may sometimes be more clear and distinct, and at other times more obscure and confuse; because it implies a Contra-

Rule of
Truth.

diction for me to know what I say, when I express any thing, and yet to have no other conception of it, besides the bare sound of the words. By the word *Idea* therefore we are to understand, not an Image represented in our Bodily Imagination, and delineated in some part of our Brain, but all that which is in our Mind, when we assert with Truth, that we do conceive a thing, after any manner whatsoever.

XII. In the Second place we infer hence, that the *Ideas* of our *Mind*, do not proceed from our *Senses*. For, as was said before, nothing is so clear an object of our *Mind*, as our *Cogitation*, neither is any thing more distinctly known to us, than this Proposition, *I think, therefore I am*: Now we can have no certainty of this Proposition, except we distinctly conceive, what *Being* is, and what *Cogitation* is; and it would be in vain for any to demand any further Explication of these Words from us, since every one understands them, and cannot be further explained without some confusion. But who will say that these *Ideas* of *Being* and *Thinking* are produced by the *Senses*, and have been convey'd to the *Mind*, by the help of *Bodily things*? Wherefore *Ideas* are not to be attributed to the *Senses*, but to the *Mind*, which hath the Power of producing them, and forming them out of it self, without any outward assistance. Tho' indeed the *Mind* be often excited to the producing of them from things that strike the *Senses*: Because this is no more, than in the case of an *Architect*, who may be inclined to Build a House from the Money which is promised him: But it would be very foolish therefore to assert, that Money had been the Original of the House.

XIII. Thirdly, We may gather that *Ideas* are of two kinds, clear and confused: Because all of them have not the same Evidence, but exceed one another in clearness and distinction. Now those *Ideas* are called clear, which are evident and manifest to our *Mind*, when it gives heed to them; in the same manner as we say that Objects are clearly beheld, when being present to us, they act strongly enough to be perceived by us, and our Eyes are well disposed to behold them.

XIV. Those *Ideas* are called *Distinct*, which are so precise, and diverse from all others, that they contain nothing, which doth not manifestly appear, to him that gives heed to them, as he ought. So when a Man feels some great *Pain*, that perception of *Pain*, is very clear to him, but is not always *distinct*: For commonly Men confound it, with their obscure *Judgment* concerning its *Nature*, which they suppose to be in the grieved part, and to resemble the *Sense* of *Pain*, which alone they clearly perceive. And the reason is the same concerning other *Qualities*, viz. *Sound*, *Colour*, *Smell*, *Cold*, *Heat*, all which they conceive to be in the Objects themselves, and think there is something like these Sensations in the *Senses*, or the *Ideas* we have upon their account. These *Ideas* therefore are called *Obscure*, because they represent things or Objects, confusedly or obscurely. Let this therefore be

The Eighth Rule of Truth.

XV. That *Idea*, or perception of a thing is clear and distinct, which represents the thing it self to the *Mind*, according to the foregoing Rules of Truth: And that obscure and confused, which doth more or less depart from the same.

For seeing that that *Idea* is more clear and distinct, which involves least doubtfulness, and which represents more parts and Adjuncts of a thing to the *Mind*, and distinguisheth it from all other things; it must follow that that Perception is clear and distinct, which represents a thing to the *Mind* according to the foregoing Rules.

The Ninth Rule of Truth.

He whose *Mind* is furnished with most, and most perfect *Ideas*, is the most knowing and understanding Man.

For seeing that every thing is made manifest by its *Idea*, and whatever is known of it, is contain'd in its *Idea*, it is clear that the more *Ideas* we have in our *Minds*, the greater must be our Knowledge: And by how much the several Perfections do evidently and distinctly comprehend more particulars, by so much the more excellent and perfect must that Knowledge be.

AN APPENDIX.

Of the Imposition, Signification, Definition and use of Names.

I. For as much as the Names or Words, we use in discourse are Marks and Signs of our Conceptions, and consequently of the things themselves, we have thought fit to add something here concerning their Imposition, Signification, Definition and Use, and this by way of Conclusion.

It hath been an enquiry amongst the Philosophers of old, whether the Names or Words we use in Speech, were from Nature, or from Custom, and Consent: Or, which is the same, whether it be natural for all Men to speak those words, by which they utter their Conceptions; or whether they were imposed on things from the free choice of Men, and invented to be put instead of our Conceptions. Epicurus ascribes the original of Names to Nature, and asserts them to be effects produc'd by the force thereof. So that the first Men, when they were struck by the Image, proceeding from the Object, and found several Passions of Love or Hatred stirr'd up in them, broke forth into some Voices, by which they designed them, no other-wise than if they had pointed at them with the Finger, or some other Bodily Gesture. And accordingly his opinion was, as Proclus tell us, Chap. XVII. That Names are as well from Nature, as are the operations of Nature that go before them, as a Vocal Sound, or the Function of Seeing; for that the same thing that sees and hears, must also name the things it sees and hears; So that the Name Nature, is an effect or work of Nature.

For the variety of Names according to Epicurus, which is found in divers Nations, is to be ascrib'd to their different Temperaments, who being affected with different Passions, at the perceiving of things, did express one and the same thing diversly, that is, by a different Voice or Sound. Whence it came to pass that those Nations, who had no Commerce with others, still kept their own Idiom; whereas those that had more Communication with others, did take in some of their Words, which were unknown to their Forefathers.

But whatsoever Epicurus may alledge to the contrary, the Names of things do not seem to proceed from Nature, but from the consent and agreement of Mens free choice.

ment of Men. As may be proved first from *Homonymy* or *Equivocation*, by which the same word is attributed to divers things; which was occasion'd by Mens joyning the same sound to different *Idea's*, so that the same Sound agrees to many *Things*, not according to the same, but different *Idea's*. As for Example, this word *Vacuum* or an *Empty space*, according to the vulgar use signifies, a place in which nothing is contained, of that which we suppose ought to be in it: As when we say that a Ship is empty, because it hath no lading. But according to *Philosophers*, *Vacuum* signifies a place in which no bodily thing is contained. In the second place, that Names have their original from the voluntary imposition of Men, is apparent from *Polyonymy*, and *Synonymy* which attributes divers words to one and the same thing: As *Liber*, *Codex*, both which signifie a Book; *Ensis*, *Gladus* a Sword. Thirdly, The same may be proved from the changing of Words, by which sometimes one Word, and at other times another is given to the same thing: as now *Aristocles*, afterwards *Plato*; now *Tyrannus*, then *Euphrastus*, and afterwards *Theophrastus*. Which would not happen so, if words owed their use to *Nature*, and not to the voluntary institution of Men.

V. Moreover we find by Experience, that Words have their signification from the imposition and will of Men, forasmuch as the same Word signifies one thing in this Nation, and another in another Nation. For what is more common than for a Name or Word, which before represented nothing to your Mind, now to signifie something from the institution of Men? For tho' words must be taken from the People, who have the Power of giving Law concerning them: Yet it is certain, that there is a kind of Speech proper only to those who follow some particular Art or Calling. And tho' as *Philo Judeus* saith, Speech be proper to Man, as *Neighing* to a Horse, *Barking* to a Dog, and *Lowing* to an Ox; yet is not the faculty of speaking Natural, as to the signification of speech, but only with respect to the sound of the Word. For the signification of every word doth not agree to it, by any force of Nature, but wholly depends on the free will of Men.

VI. WORDS therefore being instituted by Men, are the Notes, and Signs of our Conceptions, and therefore of the things themselves; whether they signifie our conceptions, or the things themselves. That they signifie the inward conceptions of our Mind, appears hence, that whenever we please, we can discover our Secrets, by words to others, they being the Interpreters of our Mind, which represents the image of our Thoughts. The word that sounds without, saith *S. Austin* 15 de Trin. Cap. XI. is a sign of the word, that lies hid within. For otherwise, except Words did intimate our Conceptions, there would be no such thing as a Lye, which consists in this, that the Mind of a Man doth disagree with the words he utters; or when we have other conceptions in our Mind, than our words import.

VII. And that Names do also signifie the things themselves, we can prove by experience; for because we cannot carry all things with us, we make use of words, for signs whereby to signifie absent things. For it is apparent, when any one calls for some particular Person, as for Example, *Socrates*, that the Name by which he calls him forth signi-

fies the thing which *Socrates* is; and when he commands him to come to him, to return answer, that the Thing is meant and not the Words. Hence the Scripture tells us, that GOD set all living Creatures before *Adam*, that he might give Names to them, conform to the Things themselves. So that it appears that Mankind makes use of Words to manifest their Conceptions, and the Things themselves.

VIII. But because when Words are wrongly understood by us, it occasions great Confusion in our *Idea's*, and also in our *Discourse*, therefore we are used to define what we mean by our Words, and to declare what we would have to be understood by them. For it often happens, that one Word, signifies many Things, by which means, the Mind may be easily confounded, by applying it sometime to the one, and sometime to the other *Idea*. For example, The antient *Philosophers* perceiving that there was something in Man, that was the cause of *Nutrition* and *Augmentation*, called it the *Soul*, which *Idea* they afterwards attributed to *Animals* and *Plants*, as finding the same Faculty in them. And discovering also in Man a *Principle of Cogitation*, they gave to it likewise the Name of *Soul*. And so from this Sameness of the Name, they took occasion to confound the *Principle of Cogitation* with that of *Nutrition*, and *Growth*, and took Things wholly different to be one and the same: Which confusion can no otherwise be avoided, than by considering the word *Soul*, only as a Sound, devoid of any meaning, and afterwards bestowing it upon that Thing alone which Thinketh, Saying, I call that the *Soul*, which is the Principle of Thinking in us.

IX. And this is that which commonly is called the Definition of a Name, and is very familiar with *Geometricians*, by whom it is rightly made to be a kind of Principle. For it is in the Power of Men, to denote a certain *Idea* by certain Names or Words, and to apply them to what they have a mind. This being the difference between the Definition of a Name, and the Definition of a Thing, that it is not in the power of the Will of Man, to make the *Idea* contain what they please. For they must needs fall into Error, who going about to define Things, attribute any thing to their *Idea's*, which they do not contain. As for example, If we deprive the name *Parallelogram* of its signification, and no longer consider it, as a Figure including Four sides, but consider it only as a naked Sound, or will have it to signifie a Triangle or Figure consisting of Three sides, we may do so, if we please, neither shall we thereby make ourselves lyable to Error, as long as we make use of the word *Parallelogram* only to signifie a Figure contained within Three lines. And therefore we may say; A *Parallelogram* hath its Angles, equal to two Right ones, and that the greater Angle in a *Parallelogram*, is subtended by the greater side, &c. But if retaining the signification of the Word, and its ordinary *Idea*, which represents to us a Figure, whose opposite sides are *Parallel*, we should still assert that a *Parallelogram* is a Figure consisting of Three sides, we should fall into Error; for then we should not define a Name, but the Thing; seeing it is a contradiction, that a Figure consisting of Three lines should have its sides *Parallel*.

From

X.
How the
Definition
of a Name
is distin-
guish'd from
the Defi-
nition of
a Thing.

From hence it follows, First, That the *Defini-
tion of Names* cannot be called in question, be-
cause they depend on the will and choice of Man.
For it cannot be denied, but that he who defines
a Name, may give such a signification to the sound
of the Word, as best pleaseth him, and maintain
that signification, which he puts upon it. But this
cannot be in the *Definition of Things*, which fre-
quently are controverted, for as much as they may
be false, and represent the thing otherwise, than
indeed it is.

XI.
The Defini-
tions of
things may
be doubt-
ful.

In the second place it follows, that since the
Definitions of Names cannot be questioned, they
are therefore to be lookt upon as *Principles*; which
cannot by any means belong to the *Definitions of
Things*, they being *Propositions*, which can be
denied by those who find any obscurity in them,
and therefore stand in need to be proved, as other
Propositions; neither are they to be taken for grant-
ed, except they be self-evident, and partake of the
clearness of *Axioms*.

XII.
Whence
Errors do
arise in the
common
Philosophy.

Wherefore they who are taught in the *Aristotelean
Philosophy*, do doubly mistake, First, By con-
founding the *Definition of a Thing*, with the *De-
finition of a Name*, and attributing to the former,
what only belongs to the latter; for after that
they have alledg'd several *Definitions*, not of *Names*,
but of *Things*, which are altogether false, and
neither express the *Essence of Things*, nor the
Idea's which we Naturally frame from them; they
will needs have us to consider these *Definitions*, as
so many *Principles*, or *Perspicuous Notions*, which
no Man is able to gainsay; inasmuch that if any
one refuse to admit them for *Principles*, they are
incens'd, and do not think such a Person fit to be
disputed with.

XIII.
The necessi-
ty of Defini-
ing Names.

Secondly, The common *Philosophers* are mi-
staken, in that they seldom or never have recourse
to the *Definition of Names*, to rid them of all ob-
scurity, and to addict them to certain and clear
Idea's, but leave them in their confusion and ob-
scurity. Hence it is that the greater part of their
Disputations are no better than *Contests* about
Words; which would be easily removed, if those
Words that involve any obscurity were defined,
and whatsoever makes their meaning doubtful and
uncertain were removed. This will appear more
fully by an Example: *Philosophers* suppose that
nothing is more evident in Nature than that *Fire*
is *Hot*; but except it be first cleared what we are
to understand by *Heat*, we shall never know, how
or in what regard *Fire* is said to be *Hot*. By *Heat*,
therefore they do understand either a certain power,
wherewith the *Fire* is endowed, to produce in us
the sensation of *Heat*, and in this case they truly
apprehend the thing as it is: Or else by *Heat*, they
apprehend a certain Quality, like to the sensation
they perceive, wherein they are mistaken, since
that is obscure, neither can it any way be made out
how *Fire* is *Hot*, after this manner. For tho' it
be clear that the cause of that *Motion* which we
experience in our *Bodies*, be in the *Fire*, yet have not
we the least ground of evidence, that the *Fire* con-
tains any thing like that which we feel, when we
stand near the *Fire*.

XIV.
It is not
necessary to
define all
Names or
Words.

But tho' the *Definition of Names* contributes
much towards the clear understanding of *Things*;
yet it is not necessary to explain all *Names* by *De-
finitions*, because that would be often superfluous,

and indeed is utterly impossible. For it is certain
that Men have many *Idea's* that are so distinct, that
those who understand the same Language, as soon
as they hear the *Names of Things*, they immedi-
ately form the same *Idea's*. So they who hear those
Names *Entity* or *Being*, *Cogitation*, *Existence*,
Certainty, *Equality*, and such like, do immediately
apprehend the *Things* that answer to them in their
Minds; and therefore it is superfluous to explain
them by *Logical Definitions*, as being most simple
Things, and such as are known of themselves. I
said also that it was impossible to define all *Names*,
forasmuch as to the explaining of any Word, we must
make use of other Words, to determin the *Idea's*,
to which the Words are addict, and those Words
again stand in need of other Words to explain
them, so that it would be necessary to run into in-
finite. For this Reason we must keep to Primitive
Words, and not easily change those which Use
hath made to pass current amongst Men.

They are much in the wrong, who when any
Word is to be defined, do not consider what Sense
Men commonly attribute to it, and that as far as
may be, they are never to recede from it. So he
that would put the Name of *Parallelogram* upon a
Triangle, would be accounted a Mad-man for his
Pains, for contradicting the *Etymology* of the
Word, and running Counter to common use and
custom. In which regard the *Chymists* are great-
ly to be blamed, who without the least profit
thence ensuing, have changed the Names of *Things*,
and assigned others to them, which have no true
Affinity at all with those *Idea's* to which they affix
them. Thus by the Name of *Sulphur* (*Brimstone*)
they do not understand that Thing, which the Vul-
gar know and call by that Name, but a liquid, odo-
rous, oleous and Inflammable Substance, which is the
Glue that joyns the Parts of dry Things together:
Neither do they by the word *Mercury*, understand
Quicksilver, but a certain most subtil and clear
Liquor, of an Acid or Sourish Taste, which readily
Penetrates every where, and easily vanisheth away.
And by the name of *Water* they understand another
far more copious Liquor, which dissolves *Salt*,
which cannot be dissolved by *Sulphur* or *Mercury*.
Hence we infer

The last Rule of Truth.

The Names of Things which we use in Philoso-
phizing, must be clear and determinate as to their
Signification; not Obscure or Ambiguous.

XVI.
The Tenth
Rule of
Truth.

For seeing that all the Things which we do heed-
fully Interpret, are delivered by us, in *External
Expressions*, the highest excellency whereof is *Per-
spicuity*, it is necessary that we make use of fit and
usual Words for the expressing of Things, and
take care to give distinct Names to distinct
Things.

H The

The Second Part of Logick. Concerning the Right Judgment of the Mind; or Proposition.

CHAP. XI.

Of Judgment, Absolute and Compared.

i.
What
Judgment
is, and that
Affirma-
tion and
Negation
belong to
it.

HAVING thus informed our selves what *Idea's* are, and how they are distinguish'd from each other, the Order we have set our selves in the beginning of this Treatise of LOGICK, requires that we now speak of their Composition, whence JUDGMENT, or the Second Operation of the Mind, as others call it, doth proceed. And herein consists the whole Sum of our Knowledge; because when our Mind hath once past a firm and stable Judgment of any thing, it thinks it self arrived to the very Top of Science. To Judge therefore, is nothing else, than to assent to those Things, of which we have clear and distinct *Idea's*; or to deny our assent to those things whilst the *Idea's* that represent them are obscure, and are perceived to be so. And therefore Judgment is a kind of Composition, by which the Mind joyns one *Idea* with another by Affirmation, or separates it from another by Negation: As when from the Perception of the Sun and Light, he assents that the Sun is Lucid; or from the Perception of the Moon and Cheese, denies the Moon to be Cheese.

II.
To Judge-
ment assent
or dissent
is required.

For it is not sufficient to Judgment, to know two *Idea's* jointly; but it is necessary, that the one be conceived to be in the other, and that assent be given to Truth as soon as it appears: For an Affirmation and Negation appertain to the Essence of Judgment; neither can there be any Judgment without Assent or Dissent. Wherefore as long as a Man sticks in doubtful Enunciations, to which the Will doth not yet yield its assent, and being Uncertain, enquires concerning the Truth of them, he cannot be said to Judge, till after a full determination of his Mind he affirms the thing to be, or denies it to be such as he perceives it.

III.
To the right
forming of
Judgment,
it is first
required,
that the
Under-
standing
precede.

To the right Forming of Judgment, it is required, First, That the Understanding do precede, and that the things be known, before that we affirm or deny any thing concerning them; since we cannot attribute ought to another thing, except we have first perceived them both. Wherefore in every Categorical or Simple Proposition, it behoves us to have a distinct Perception of the Terms, viz. the Subject and the Attribute, before we assent to the Conjunction of them; in every Hypothetical, of the Connexion of the Antecedent and Consequent; in a Modal, of the Mode and the Thing said; in a Disjunctive, of the Repugnance between the Antecedent and the Consequent; in a Copulative, of their Simulty or Existing at one and the same time. And the same Caution is to be used in refusing our Assent to any Proposition; seeing that Men for want of this Observance fall into great Errors, and judge preposterously of things. How many are there that judge the Earth to be plain or level; that the Moon has the Figure of a Dish or Platter; that the Stars are very Little things, and that the Sun is much less than the Earth; because they never had a true Perception of any of these things, but trusting to their Infant Prejudices, believe

nothing to be True, but what agrees with the report of their Senses.

Wherefore it is requisite in the next place, for the avoiding of all Mistakes in Judging, to take a firm Resolution, not to admit any of those things for Truth, which formerly we believed such, before we have called them to a fresh and accurate

Account, according to the foresaid Rules or Precepts of clear and distinct Perception; and that we suspend our Judgment, till we be certain of their Truth. For he who withholds his Assent is thereby secured from Error; and he who assents to what he hath well understood, is so far from being Mistaken, that he embraces and enjoys Truth.

In the Third place, To avoid our mistake in Judging, we must distinguish between the Things and Occasions in which we are to pass our Judgment: For either we are conversant about the Search of Truth, or about the things that belong to Life, and which are considered with relation to Practice. If we consider things under the first respect, we must suspend our Judgment, when they are not fully known by us, that is, when any obscurity or confusion appears in the things we have under Examination. If we consider them the Second way, we need not make use of so great Precaution, especially when the necessity or opportunity of Business doth not allow us sufficient time for an exact Disquisition; for otherwise we should often let slip an Occasion, before we could resolve our Doubts about the matter. Wherefore in cases where delays are prejudicial, it is best to examine the thing only so far as Time permits, and to embrace what appears for that time clearest and best to us. And having once past our Choice, we are no longer to consider it as Doubtful, in reference to Practice; but as a thing most evident and certain, as if we had been assured of it by a clear and manifest Demonstration.

Compared, or Relative Judgment, is between more things, which we refer to another Third thing; in which, if they agree, they are called the Same; but if they disagree, Diverse. For Comparison is not the simple Consideration of one thing, to which we Assent or Dissent; but the Comparing of one thing with another in Quantity or Quality: In Quantity, when we enquire not only of the Dimension, but of the Value, Virtue, or Perfection of a thing; for from hence comes the Equality and Inequality, Greater and Lesser. For things that are compared together in Quantity, are such as have either the same Quantity one as the other, or a greater or lesser.

Things that agree in the same Quantity, are called Even or Equal, because they are compared with respect to something, which is found in the things compared in an Equal Proportion. As at the Equinoxes, the Night is equal to the Day: Hector is equal to Achilles in Bodily Valour. Forasmuch as by the Name of Quantity, is not precisely to be understood Mathematical Magnitude, but any Equality or Inequality, whether it be measurable, or not.

Things that differ in Quantity, are called Uneven, or Unequal; and such are either Greater or Lesser. Things Greater, are such as exceed others in Quantity, or which by their Quantity, exceed the Quantity of those things wherewith they are compared.

Those

IX. Those things are *Lesser*, which in Quantity are exceeded by others: For the Lesser is made use of to set forth the Greater Excellence, Dignity, Number, or Usefulness of the other. Thus Plato is said to be a more Excellent Philosopher than Socrates: A Dog swifter than a Wolf. A Comparison in Quality is, when the Similitude, that is, the Proportion; or Dissimilitude, that is, the Disproportion of things is consider'd. Where by the Name of Quality; we are not to understand a Physical or Natural, but a Logical Quality; such as is Affection, Nature, Faculty, Action, Passion, &c.

Hence those Things are called *Like*, which agree in Quality; or which being compared together, are found to have some like Affection or Faculty. As when we compare the Sun and the fix'd Stars, with respect to Light which is found in them both, we say they are like one another. For things compared are not alike in all things, but differ also in many Specialties. But when we compare those parts or respects wherein they agree, from one Like we rightly conclude the other, because the Effects and Adjuncts of like Causes and Subjects are alike, and so on the contrary.

XI. Those things are *unlike* whose Quality is diverse; or those are diverse Comparates, which differ in Qualities, Actions, and Passions. So, A Wise man is unlike to the Moon; A Constant man is unlike to a Reed shaken with the Wind. Hence from things that are Unlike, Unlike things are concluded; because the Effects of Unlike Causes are unlike, as are the Adjuncts of unlike Subjects, and on the contrary. Wherefore because a Reed is easily driven this way and that way by the Wind; and S. John is not so easily shaken, therefore in this regard, S. John and a Reed are unlike. Here we are to take notice, that the Unlikeness is to be restrained within the bounds of that Quality, wherein the Comparison is made.

CHAP. XII.

What a Proposition is, and how manifold.

I. A Proposition, or Enunciation, according to Aristotle, is an Oration or Speech, which affirms or denies; or an Oration, that signifies either true or false. From which Definition it clearly appears, that to every Proposition two Forms at least are required; the One, of which something is affirmed or denied, which Term is called Subject; the Other, which is said or denied of another, which Term is called the Attribute: As when I say, God is Existing; God is the Subject, and Existing the Predicate.

II. But because it is not sufficient to conceive these two Terms, except by our Cogitation they be joyned together, or disjoyned; the word *Is*, is the Sign of the Mind's affirming, that is, of joyning these two Ideas of God and Existing, as agreeing together. But when I say, God is not finite, the word *Is*, joyned with the Negative Particle Not, imports an Action contrary to Affirmation, or denotes, that we look upon these two Ideas as repugnant; forasmuch as in the conception of Finiteness something is included, which is contrary to the Nature of God.

III. Yet sometimes we express Propositions after another manner: As when we say, Charles walk-

eth; Injustice thrives amongst men: because under these words, as well the Connecting word *Is*, as the Predicate are contained: And therefore these Propositions are the same as if one should say, Charles is walking; Injustice is thriving amongst men: Subject, Yea, it is customary with Logicians, as often as the word *Is*, is used without any Predicate following it, to understand the Predicate to be comprehended under it: For this Proposition, Man is, is resolvable into this other, Man is existing. It matters not therefore whether a Proposition consist of Three words, as Charles is walking, or of Two, as Charles walketh, or One word only, as Ambulo, I walk; the Latin word including all the Parts of a Proposition in it.

From this Explication of a Proposition it follows, that all Propositions are either Affirmative or Negative: For since the Judgment of our Mind is twofold, viz. Assent and Dissent, Propositions which are the Interpreters of it, must likewise be divided into Affirmative and Negative. Which indeed is the first and chiefest Division of them, as being taken from the Copula or Connecting word it self, or from that Action of the Mind, which either joyns the Attribute with the Subject, or separates it from it.

Wherefore concerning the Judgment of an Affirmative and Negative Proposition, let this be The First Rule.

That is an Affirmative Proposition in which the Subject and Attribute are joyned, or do agree; and The First Rule. Negative, in which they are disjoyned, or disagree.

For a Thing is then affirmed to be what it is, when the Predicate or Attribute agrees with the Subject, or when it is one and the same thing with it: As when we say, Man is an Animal. But a thing is pronounced not to be, what it is not, when the Attribute differs from the Subject, and agrees not with it: As when we say, Man is not a Beast, because Man is declared not to be such, as indeed he is not. This Division of a Proposition is according to Quality; because when any one asks, of what kind the Proposition is, it is answered, Affirmative or Negative.

VI. We are to observe, that in an Affirmative Proposition the Attribute is to be taken in all its Comprehension, but not in all its Latitude. As when I say, Every Circle is a Figure; whatsoever is contained in the Idea or Essence of a Figure, the same is affirmed of a Circle; but yet the word Figure is not taken in its whole Latitude, for it is of much larger extent than that of Circle; and therefore this Proposition cannot be simply converted in saying, Every Figure is a Circle. Wherefore in this Proposition the Attribute is restrained by the Subject, and reacheth no farther than the Subject doth.

VIII. But the case is different in a Negative Proposition; as, No Circle is a Square: For here the Attribute is taken in its whole Latitude; so as that we may say as well, that No Square is a Circle, and all Squares must be denied of a Circle. But the Attribute is not taken according to the whole Comprehension of its Idea, as if all the Attributes of a Square, were to be denied of a Circle: For a Circle and Square agree in the Idea or Notion of Figure.

There

IX. There is another *Distinction* between Propositions, which ariseth from the Subjects, that go before the Copular according to which they are called, *Universal*, *Particular*, or *Singular*. An *Universal Proposition* is that to whose Subject a Note of *Universality* is annexed, such as *Every*, or *All*, *None*. As, *Every Man has a Soul*, because *Man* is a common Term, which is taken in its whole Latitude. But when a common Term is only taken in an undeterminate part of its *Extension*, with these Notes, *Some*, *Some Body*, &c. then it constitutes a *Particular Proposition*, whether it Affirm, as *Some Lovers are miserable*; or deny, as, *Some Courtiers are unjust*. But if the Subject of the Proposition be *Particular*, it makes a *Singular Proposition*, as *Charles I. now Reigneth in England*. And this *Distribution* of a Proposition, into *Universal*, *Particular* and *Singular*, is said to be made with respect to *Quantity*, because when any one asks, *Quanta* (of what extent) the Proposition is, we fitly answer, that it is *Universal*, *Particular* or *Singular*.

The Second Rule.

Concerning the Judgment of an Universal, Particular and Singular Proposition.

X. The value of these Propositions is to be Estimated, from the Extension and Limitation of the Subject and Attribute.

XI. That we may the more exactly distinguish *Universal Propositions* from *Particular*, we are to take notice of a two-fold *Universality*, the one *Metaphysical*, the other *Moral*. *Metaphysical Universality*, is when a thing is taken according to its whole *Extension*, without any *Exception*: As, *Every Body is Extended*: For this admits no *Exception*. *Moral Universality* is that which hath *Exception*; because in *Moral Things*, it is only minded whether things be so for the most part, as they are declared to be. As if one should say, *All Singers have this fault, that they never will be entreated to Sing, but when not entreated, they can never leave Singing*: Because it is sufficient if it commonly be so. For seeing that such Propositions as these, are not so general but that they admit of *Exception*, nothing can be rigorously infer'd from them; since it may be false of this or the other particular *Singer*, that he will never be *Entreated to Sing*, and never cease *Singing* when not *Entreated*.

XII. There are other Propositions that are *Universal de Generibus Singulorum*, but not *de Singulis Generum*, that is, of all the Species contained under one *Genus*; but not of all the Particulars of the same kind: As, when it is said that *all living Creatures were saved in the Ark of Noah*, which is not so to be understood, as if all, of all the Species of *Animals* had been shut up in the *Ark*, in the time of the *Deluge*; but only that some of all kinds were there saved.

XIII. Besides the *Universal*, *Particular* and *Singular Propositions*, there are those which are called *Indefinite*, which tho' they have an *Universal Subject*; Yet the same is taken neither *Universally* nor *Particularly*, but *Indeterminately*: As, *Man is a Living Creature*. *A Triangle has Three Angles equal to Two Right ones*. Because no *Universal Note* as *Every*, *None*, or *Particular*, as *Some*, *Some one*, is put before *Man* and *Triangle*.

A Proposition in general is divided into *Simple* and *Compound*. That is a *Simple Proposition*, which consists only of one Subject and Predicate. As, *Man is a Living Creature*, *A Loadstone draws Iron*. *Compound Propositions* are such as consist of more Subjects and Predicates: As, *Peter and John, went up at the ninth Hour of Prayer*. Where this Attribute *went up*, is not affirmed of one Subject, but of more than one, viz. *Peter and John*. And such Propositions as these are Equivalent to two or more Propositions; for if, this Proposition were to be explained, we must do it by these two Propositions, *Peter went up, John went up*.

XV. Words *Adjective*, or *Connotative*, make a *Complex Term*, whether they be put alone, or joyned with *Substantives*. For the Word *Wise*, doth confusedly signify the thing, in which *Wisdom* is; but denotes *Wisdom* distinctly. And when I say, *a Wise Man*, in these two Words a kind of Proposition is contained: For it comes to the same thing whether I say, *a Wise Man*, or *a Man that is Wise*. Wherefore every *Adjective* or *Connotative Term*, doth include a Proposition, which since it accedes from without, to the Proposition called *Principal*, it may be rightly called an *Adjunct*, or *Incident Proposition*.

The Third Rule.

Of the Judgment of a Simple and Compound Proposition.

XVI. The Simplicity or Composition of a Proposition is taken from the Combination or Disjunction of the Terms, that is, of the Subject and Predicate, whether the same be single or manifold.

XVII. Compound Propositions are of two kinds; for some are such in which the Composition is Evident; others again in which it is more hid, which the Logicians therefore call *Exponibiles*: Of the first sort are Propositions, *Copulative*, *Disjunctive*, *Conditional*, *Causal*, *Relative*, and *Discretive*.

XVIII. Copulative Propositions are such as include more Subjects and Predicates, joyned by an *Affirmative* or *Negative Conjunction*. As when I say, *the Sun and Moon illuminate the Earth*; for here I joyn *Sun* and *Moon* together, and affirm of them both, that they *illuminate the Earth*. For the parts of a *Copulative Proposition*, are entire *Simple Propositions*, which have another Predicate or Subject.

XIX. Disjunctive Propositions are those in which the Disjunctive Note or, *either*, *whether*, and the like is found; As, *a Man either has, or has not a Child*. *Either the Earth is mov'd about the Sun, or the Sun about the Earth*. The truth of which Propositions, depends upon the necessary Opposition of the Parts, between which no Medium can be assigned. And therefore this *Disjunctive Proposition*, *It is either a Man, or an Animal, is false*, because the Parts are not opposite to each other. As is likewise this, *It is either Peace or War*, because there may be a *Truce* or *Cessation of Arms*, which is a Mean between *War* and *Peace*. So that to the absolute Truth of *Disjunctive Propositions*, it is necessary that they have no Mean at all; but to their being *Morally true* it is sufficient, if commonly they have none.

XX. Conditional Propositions consist of two Propositions, joyned by the Conditional *If*, as; *If God be merciful, he will forgive Sinners*. *If that be a Triangle,*

Triangle, it hath three Angles equal to two Right ones. The First, In which the Conditional is put, is called the *Antecedent*, and the other the *Consequent*. And it is to be noted, that the Truth of an *Hypothetical* or *Conditional Proposition*, doth not consist in the Truth of the *Antecedent* or *Consequent*, but in the Union and Knitting of them both by the Conditional *If*; for a *Conditional Proposition* may be true, tho' both its Parts be false; as *If a Tree walks it hath Feet*.

XXI.
Others Causal.

Causal Propositions, are such as contain two Propositions, joyned by the *Causal Conjunctions* *Because*, *That*; As, *A Covetous Man loves no Body*, because he confides only in himself. *Kings are often raised to a Throne*, that they may be miserable. For to the Truth of such Propositions as these it is requisite, that the one of them be the cause of the other, and therefore both of them must be True. For what is false hath no Cause, neither can it be the Cause of another thing.

XXII.

Others Relative.

Relative Propositions, are known by some Note of Comparison; as *Where the Treasure is, there is the Heart also*. *A Woman is so far to be esteemed, as she is Vertuous*.

XXIII.

Others Discretive.

Lastly, *Discretive Propositions*, are such in which we frame different Judgments, and determine the said Difference by such Signs as these, *But*, *For*; As, *Tho' GOD be Merciful, yet he is Just*. The beloved thing may be separated from a Lover, but Love not. The Truth of these depends on the Truth of their Parts, and of the separation which is put between them. Tho' both the Parts were true, yet because there is no opposition between them, this would be a ridiculous Proposition. *A Covetous Man Loves Riches, and yet cannot endure that any one should be Liberal towards the Poor*. A *Discretive* is the only Proposition that is excluded from the Composition of a *Syllogism*.

XXIV.

Of Propositions some are Subaltern, Contrary, Subcontrary, and Contradictory.

Amongst Propositions that have the same Terms, and disposed in the same Order, but modified with various Quantity or Quality, are reckon'd up the *Subaltern*, *Contrary*, *Subcontrary* and *Contradictory*. *Subaltern Propositions* are an Universal, and particular of the same Quality: As, *Every Circle is a Figure*; *some one Circle is a Figure*. *Contrary*, are two Universal Propositions of divers Qualities: As, *Every Man is Rich*, *No Man is Rich*; which may be both false. *Subcontrary Propositions*, are two particulars of divers Qualities; As, *Some one Man is a Physician*; *Some one Man is no Physician*. *Contradictory* are such as differ in Quantity as well as Quality; As, *Every Man is a Living Creature*, *Some one Man is no Living Creature*. Which cannot both of them be true, nor both false.

CHAP. XIII.

Concerning the Truth and Falshood of Propositions.

LXIX
Truth is found in three things

It is commonly said that *Truth* and *Falshood* are found in these three Things; viz. In the *Mind*, in *Things*, and in *Propositions*. *Truth* is in the *Mind*, as in its Subject: So things are said to be true, in the *Divine Intellect*, because they had there from Eternity, their objective and known Being: Which does not properly place any Eternity in them, but in God. *Things* are said to be True, when they have such an Essence as they ought to have, or when they comport with their *Idea*; and

those false which disagree with their Definition or Essence. So GOD answers to that *Idea*, which he himself hath of *Being*, Infinite, Immenſe, Eternal, &c. But the *Sun* is not true God, because it differs from that form of Cogitation which we have concerning God.

The Truth of a Proposition, consists in this, that it pronounceth a Thing to be such as it is: As when I say, *the Earth is Round*, it is a true Proposition, because I Affirm that of the *Earth*, which belongs to it, viz. a Round Figure. So likewise when I say, *A Beast is not Rational*, it is a true Proposition, because I remove from a Brute what does not belong to it. Wherefore Truth is said to be the Property of a Proposition, and to which it peculiarly doth belong. For since a Proposition is either Affirmative or Negative, that wherein the Attribute is affirmed to be in the Subject, is True, that is, conformable to the Object, if it be really in it; and False if it be not in it. And so a Negative Proposition, in which the Attribute is denied to be in the Subject, is True if it be not in it; but False if it be in it.

The Truth which consists in the Connexion or dissent of both extremes, is called *Objective*; but *Subjective* or *Formal Truth*, is the Judgment or Act of the Mind, by which the extremes of a Proposition are joyned together, or disjoyned as far as the Judgment agrees with the thing it self. The same Proposition cannot be both True and False; for then Contradictories would exist together. For suppose some Affirmative Proposition; if it be true, the Attribute agrees with the Subject; if False, it doth not agree. And therefore, if we should suppose it to be True and False at once, then must it at the same time agree and not agree. Now it is a contradiction that the same thing should agree and disagree with the same thing; or that the same Attribute should be, and not be in the same Subject. It follows also, that we cannot at the same time Assent to, and Dissent from the same thing, because both those Judgments are opposite, and that the one excludes the other: Which would happen, if the same Affirmative Proposition, were at the same time True and False; for we should assent to it, if the Attribute did agree with the Subject; and should deny our assent, if it did not agree; which plainly implies a Contradiction.

If you object, this Copulative Proposition, *Claudius and Theophilus Gaze upon the Stars*, when only one of them beholds the Stars, will be both True and False; seeing it is True, that the one beholds the Stars, and the other not. I answer, that this Proposition to speak absolutely is False, forasmuch as Copulative Propositions import a Sameness of Time, and their Truth depends on both extremes, so that if one of them doth not agree with its Attribute, it renders the Proposition False. As, suppose any one should say, *A Good Life and Riches are necessary to Salvation*, this Proposition would be False, because that tho' a Good Life be necessary to Salvation, yet Riches are not. But if we take this Proposition without including any Sameness of time, then it will furnish us with two Mental Propositions, and so it will be True, *Claudius Gazeth on the Stars*, and *Theophilus does not*; and on the contrary.

Tho' it be necessary that all Propositions be either True or False, yet are not all equally true and certain: Or which is the same, the Attributes do not agree with the Subjects in the like degree of necessity, false.

II.
Wherein the Truth and Falshood of a Proposition doth consist.

III.
Truth is either objective or subjective, which is also called Formal.

IV.
One and the same Proposition cannot be true and false at one and the same time.

V.
An Objection answered.

VI.
Propositions necessarily true, and necessarily false.

necessity. For some *Attributes* are after that manner in their Subjects, that their *Subjects* cannot be without them. As *Extension*, with respect to *Bodily Substance*; *Cogitation*, in reference to the *Soul*. And therefore this Proposition, *A Body is an extended Substance*; *A Soul is a thinking Substance*, are called necessary, because their Predicates and Subjects are united by an Indissoluble Band. Whereas other *Attributes* are at such a Distance from those Subjects, that it is impossible for them to agree with them, as a *Stone* with relation to *Man's Unevenness* with respect to the Number *Two*; and therefore these Propositions, *Man is a Stone*; *The Number Two is Uneven*, are said to be necessarily false; because there is a manifest Repugnance, that the Predicate *Stone* should agree with *Man*, and *Unevenness* with the Number *Two*. Both these kind of Propositions, by reason of the immutable Consent or Dissent of their Terms, are said to be of *Eternal Truth*.

The Fourth Rule.

Concerning the Judgment, or a Proposition necessarily true or false.

VII.
The Fourth Rule.

That Proposition, whether Affirmative or Negative, is true, wherein things to be joyned, because of the immediate and indissoluble Band of the Terms, that is, of the Subject and Predicate, are conjoyned universally of themselves, and reciprocally; or are disjoyned, because of the impossibility or repugnancy of their Terms. And on the other hand, That Proposition is false, wherein Things to be joyned, are disjoyned, and things Dissentaneous conjoyned.

VIII.
The Rule explained.

For seeing that Objective Truth consists in the Agreement or disagreement of both Extremes, viz. of the Subject and Attribute, it must follow that that Proposition in which things consentaneous are Conjoyned, because of their indissoluble Connexion, is necessarily true. As, *Man is a living Creature*; because Man, without a living Creature, cannot be. And, *Man is not a Beast*, is necessarily true; because it is repugnant that Man should partake of the Nature of a Beast. In like manner these Propositions, *Man is not a living Creature*, and *Man is a Beast*, are necessarily false; because it is a contradiction that living Creature should be separate from Man, or that Man should be a Beast.

The Fifth Rule.

IX.
The Fifth Rule.

That Proposition, whether Affirmative or Negative, is contingently true, wherein the Subject and Attribute do only sometimes agree, or not agree, because of their separable connexion; and that false, in which the thing is otherwise exprest than it is, whether it be propounded Affirmatively, by conjoyning things which are to be disjoyned; or Negatively by disjoyning things to be conjoyned.

So this Proposition, *The Air is enlightened*, or *Man runs*, is only contingently true; because the Subject in the first Proposition, viz. *Air*, may be without its Attribute, as being but sometimes enlightened: And the Subject in the second Proposition, viz. *Man*, may likewise be without its Attribute, seeing it is but sometimes that he Runs. But if any one, whilst the Air is enlightened, should say the Air is not enlightened, the Proposition will be false; be-

cause he separates Light from the Air, which then agrees to it. Or if when it is dark, he should say, The Air is Light; because he joyns things that ought to be disjoyned.

Hence it appears, what is a probable Proposition, and Opinion, as also what Science and Error is. For seeing that the probability of a Proposition consists in this, that it approacheth more to Evidence than Obscurity, that Proposition is to be accounted probable to which the Mind assents, because of the likelihood there is of the Attributes agreeing with the Subject, or on the contrary, of the Attributes disagreeing with the Subject. Whereas Science is, when the Truth of a thing is certainly and evidently perceived by Reason. For since the certainty of a Proposition depends of its Evidence, that Proposition is accounted certain to which the Mind firmly adheres, and whose Attribute it judges doth necessarily agree with the Subject. And lastly, Error is, when the Mind assents to a false Proposition for a false Reason, which it apprehends to be a true one.

There are other Propositions, which tho' they be neither necessarily true nor false, yet must needs be either true or false disjunctively; such are those Propositions whose Predicates do only contingently agree with their Subjects, and may be absent or separate from them. As, *Rich*, *Powerful*, *Married*, true or false with respect to *Man*. Wherefore these Propositions, *Circulus is rich*; *Galigula is powerful*; *Thomas is a Husband*, are said to be Contingent, that is, they are true in such a manner, as that they may be false; and yet it is necessary for them to be either true or false separately. Because every Proposition, in contingent matter, is either true or false disjunctively, that is, cannot be deny'd to be either true or false. It may indeed be deny'd, that such a Proposition is necessarily true or necessarily false; but it cannot be deny'd, but that it must be either necessarily true, or necessarily false disjunctively.

A true Proposition in Contingent Matter, cannot be changed into a false one. Which is thus proved; because if this Proposition, for Example, *John walketh*, be true, tho' but in one instant of time, yet it cannot be said to be false in that very instant wherein it is true. But it is true at one instant; therefore for that instant it cannot be false. Moreover, this Proposition considers *John walking* such a time, at which time wherein he is supposed to walk, it is always true; or if it signifie another time, in which it may be *John doth not walk*, in that case the Object is changed, and therefore is not the same, but another Proposition.

If you say, That during the Time wherein this Proposition, *John walks*, is pronounc'd, *John*, who before walked, may cease from motion, and rest; and thus this Proposition, *John walks*, which before was true, will be changed into a false one.

To this I answer, That tho' at that time wherein this Proposition, *John walks*, is pronounc'd, *John* may cease to walk; yet the Proposition continues true notwithstanding, if once it was true. Because it either determines the time wherein he walks, or that wherein he did walk, and in this respect the Proposition is true; or else absolutely denotes some difference of time in reference to which it is verified, and therefore with respect to that Time wherein he hath walked, is true.

XIII.
Objection.

XIV.
Answer

XV. The Difficulty is greater concerning the truth of Propositions of a future Contingent: For it is evident enough, that of opposite Propositions of the Present time, one is true and the other false: As, *Peter speaks*, and *Peter doth not speak*. But it may be doubted, whether the same truth be found in those Propositions that respect the Future time: As, *Peter will speak to Morrey*, *Peter will not speak to Morrey*. But it seems certain, that Propositions of a future Contingent, have a determinate truth or falsity: For supposing *Peter* to exist, these two Propositions, *He shall speak*, *He shall not speak*, are contradictory: Now as two Contradictories cannot be together, so it is impossible they should be both of them true, and therefore one or other must be true only, and therefore *Peter will either speak, or not speak*; if he does, the Proposition is true; if he does not speak, it is false: So that one of them is determinately true, and the other false. Again, such as are the Propositions of the Present or Past time, with respect to Truth, or Falsity, such are the Propositions of the Future: But one of these is determinately true, and the other false; Therefore, &c.

IX. The Major is clear: For he that pronounceth that a thing will be, and that it will not be, doth speak as true, as he who pronounceth that a thing is, and that it is not; or that a thing was, or that it was not; because it is necessary, that one of them must come to pass.

XVI. Neither doth it hinder, that we know not which of the Propositions be true, and which false: Because the Truth of Propositions doth not depend upon its being known, or unknown; but upon the Being, or not Being of the thing. Besides, it is certain, that GOD knows which of them is true, and that he can reveal the same to whomsoever he pleaseth.

CHAP. XIV. Of Division, and Definition.

I. Having explained the Nature of Propositions, and clearly and distinctly unfolded their Affections of Affirmation and Negation, Universality and Particularity, Truth and Falsity, it only now remains, that we add something concerning Distribution and Definition, which are accounted the most Scientific, or conducive to Science of all other Propositions; and are nothing else, but Tokens or Instances of a clear and distinct Perception; or, if you will, they are Primary Enumerations, Axioms of solid Judgment, and Maxims worthy of all belief.

II. **DI**VISION therefore is the Distribution of some Whole into Parts; As, of a *Living Creature* into *Man* and *Beast*; of *Number* into *Even* and *Uneven*. Now Division will not a little conduce to our acquiring a clear and distinct Knowledge of Things, if so be we know how dexterously to make use of it. For seeing that almost in every Object there are many things to be considered, which because of the Difficulties wherewith they are involved, cannot be clearly apprehended by us; it is needful to resolve them into Parts, that so having by Division removed all Confusion, the Particulars may more clearly appear such as they are.

III. Division is twofold; the one *Real*, the other *Mental*. The *Real* is, whereby a Whole is really and indeed divided into Parts; as a *House* into the

Roof, *Walls*, *Foundation*, &c. of which it consists. **A** Mental Division is, when we divide a Whole only by the help of our Understanding: As when we consider in GOD, his Goodness, Omnipotence, Eternity. For it doth not always follow, that the thing which our Mind distributeth into Parts, is compounded and divisible; but that only our Conception of it is compounded, and unable to understand so many Attributes under one and the same Notion. Division is manifold, according to the threefold kind of a Whole and its Parts. For it is either of the Whole Genus into its inferior Species, or of the Species into its Individuals: As the Division of Substance into Mind and Body; of Mind, into an Angel, or Man's Soul. The other is of an Integral Whole into its Parts; which is properly to be called Partition: As the Division of the Body of Man into Head, Teeth, Hands, and Arms. The third and last, is the Division of an Essential into its Essential Parts; as the division of Man into Mind and Body. And these Three are called Primary Divisions.

There is this difference between the two former Divisions: In the Division of a Genus into Species, and of a Species into Individuals; the thing Divided may in the Nominative Case be predicated, of the several Parts that divide it: As when *Living Creature* is divided into *Man* and *Beast*, *Living Creature* is express in the Nominative of *Man* and *Beast*; as *Man* is a *Living Creature*; a *Beast* is a *Living Creature*. But in the Division of an Integral into its Members, the thing divided cannot be predicated of the Dividing Members, but in an Oblique case; as when a Body is divided into *Head*, *Breast*, *Belly*, &c. it cannot be pronounced of the Parts, but in an Oblique: For we cannot say, *the Head is the Body*, *the Belly is the Body*, but part of the Body. And the reason of this difference is, because the whole Essence of the Genus is included in the Species, whereas the Nature of the Whole is not in every Part.

The other Divisions are called Secondary; as a Division of an Accident into the Subjects, in which it is found. As if we should say of the things that are moved, one is the *Earth*, another is the *Moon*, &c. A Second, is the division of a Subject into its Accidents; as when a Subject is ranged or distributed according to its Accidents. As for Example, Some men are Learned, others Ignorant; some Good, and others Wicked. The Third, of an Accident into its Accidents; by which an Accident is divided, not by its own Differences, but by other Accidents of a different kind: As when we say of *White things*, some are hard, others soft, &c.

Moreover, there are some Conditions required to the constituting of a right Division. First, That all and every one of its Parts be exactly enumerated, without omitting any that belong to it; so that the Dividing Members may exhaust the Divided Whole, and neither be more extended or contracted than it: As, *Even*, and *Uneven*, do comprehend the whole extent of this Term, *Number*, seeing there is no Number which is not in it self either Even, or Uneven.

The Second is, That both parts of the Division be as far as may be expressed in positive Terms. For the Attributes of a thing that is distributed, may

Division.
The First

VIII. The Second.

may be better understood by *Positive Terms*, than by *Negative*. I add, *as far as may be*, because it sometimes happens, that the *Positive Thing* wants a *Positive Name*, and so we are forced to use a *Negative* in the dividing of it: As when we divide *Living Creature* into *Rational and Irrational*; Or *Substance* into *Material and Immaterial*.

IX. The Third Condition is, That the Whole be distributed into its nearest Parts: According to this Rule, it would not be well done to divide *Substance* into *Rational and Irrational*; because these are not immediately contained under *Substance*; but under *Living Creature*.

The Sixth Rule

Of the Judgment of Distribution.

X. That Distribution or Division is the most perfect of all, which doth honestly and equally divide a Whole into its Parts; whether it be a Genus into Species, or an Integral into its dividing Members, or a Subject with respect to its Accidents, or an Accident into the Subject, to which by the Rights of Division they belong.

XI. Thus the most perfect Distribution of a Genus is, when all its Species are Enumerated: As if one should say of *Living Creatures*, some *Walk*, others *Fly*, others *Swim*, others *Creep*, and others are *Plant Animals*. An *Integral Whole* is well divided, when all the Parts that constitute it are instant'd: As the Parts of a Man are, *Head, Breast, Belly, Arms, Legs, &c.* That is a perfect Distribution of a Subject, with respect to its *Adjuncts*, when the *Adjuncts* are reduc'd to certain *Heads*, and these again subdivided into others: As when we say, In *Man* there are some *Adjuncts* of the *Soul*, and others of the *Body*; those of the *Soul*, are *Knowledge, Virtue, &c.* those of the *Body* are *Health, Beauty, Tallness, Strength, &c.*

XII. DEFINITION is that which manifests the Nature of Things, shewing why they are, and how they are distinguished from others. There are two things principally that constitute a *Definition*, *Genus* and *Difference*. By the first we understand the agreeableness which the Thing Defined hath with others, that are of the like nature with it. By the *Difference* we are informed, how it differs from the same, and what Rank it keeps amongst *Real Beings*. As for Example, when we define *Man* to be a *Reasonable Living Creature*; by a *Living Creature* which is the next *Genus* of *Man*, we understand something that is common to other things like unto us, viz. the *Beasts*. And by *Reasonable*, which is the *Difference*, we clearly perceive our Distinction from them; forasmuch as no *Beasts* are partakers of *Reason*. Definition therefore is that, which by exhibiting the *Essential Parts* of the Thing Defined, expresseth its Nature; as in the foregoing Example.

XIII. We are to observe, that every *Genus* is not sufficient to lay open the Nature of a Thing, but the Nearest only: Partly, because it contains all the *Genera* above it, so that by expressing it we include all the rest: For he that affirms *Man* to be an *Animal*, doth consequently affirm him to be *Living, Corporeal* and a *Substance*, and whatsoever else can be imagined higher. Partly, because there is no other *Genus* can more fitly be joyned with the Specific Difference, than the nearest; nor which doth more correspond with it.

Amongst *Definitions* some are *Essential*, which properly deserve the Name of *Definition*; and are those which are explained by their *Essential Degrees*. By *Essential Degrees* I mean *Essential Attributes*, which constitute the Nature or *Essence* of a thing. And these are only *Genus* and *Difference*; as, *Animal* and *Reasonable* with respect to *Man*. Other *Definitions* are *Accidental*, and less exact, which express the thing by some *Properties* or *External Causes*, as when we define *Man*, to be a *Creature made after the likeness of God*. For tho' Property be an *Essential Attribute*, yet not in that Sense as if it did constitute the *Essence* or Nature of a Thing; but because it immediately follows the Nature of a thing already constituted. As, *Partition* and *Mobility* with relation to a *Body*. Wherefore the first Definition is called a *Perfect Definition*, because it consists only of Causes that do constitute the *Essence*, and by them doth most fully and perfectly lay open the Nature of the thing: Whereas the second Definition is called imperfect, or a *Description*, because it defines and explains the Thing by other ways, than by its Causes.

Yet we are not to think, that all things that are objected to the *Mind*, may be comprehended in a *Definition*; but it is required, that the Thing which is to be defined be *One*, that is of one *Essence*; for those Things which involve a manyfold Nature, cannot be manifested by a *Genus* and *Difference*. The Second is, That it be *Universal*; for seeing that Definition is a Declaration of the Nature of a Thing, it is necessary that we divest it of all particular Circumstances, that it may be viewed such as it is. Thirdly, No *Universal Nature*, but a *Species* can be exactly defined; and that because nothing but a *Species* can consist of a *Genus* and *Difference*; and therefore seeing that the *Supream Genus* does want them, it follows that the Things which are defined must be either *Species* of the lowest Rank, or Intermediate: Which also will but be obscurely defined, without their immediate *Genus* and nearest *Difference*.

There are *Rules* and *Precepts* of a right *Definition*. First, That the *Definition* must be of the same extent with the Thing defined, and agree to all those things which the Thing defined agrees with. As for Example, because *Animal* agrees to a *Man*; therefore a *Corporeal Substance* endowed with *Life, Sense* and *Motion*, which is the Definition of an *Animal*, must agree to *Man* also.

Secondly, That nothing be wanting or rebounding in the *Definition*, but that only those Words be made use of, that are necessary for the explaining of its Nature: Wherefore this *Definition* of a *Man*, That he is a *Reasonable, Mortal Animal*, is Superfluous, because the Word *Mortal* is not needful to the Definition of a *Man*.

The Third, That the *Definition* consist of that which is more known: For seeing that a *Definition* is declarative of the *Essence*, it must therefore employ clearer Terms; lest we should be guilty of endeavouring to explain an unknown thing, by that which is more unknown, and so instead of attaining a clear and distinct Perception, should fall into Obscurity and Confusion. Wherefore the common Definition of time, that it is, *The Number or Measure of Motion*, cannot be good, seeing it is evident, or apparent, that Time doth as well Measure Rest, as Motion, since we say, as well that a thing hath rested so long, as that it hath been in Motion for that time.

XIV. Of Definitions some are Essential, others Accidental.

XV. What things are required to a perfect Definition.

XVI. The Second is, That it be Universal; for seeing that Definition is a Declaration of the Nature of a Thing, it is necessary that we divest it of all particular Circumstances, that it may be viewed such as it is.

XVII. There are Rules and Precepts of a right Definition. First, That the Definition must be of the same extent with the Thing defined, and agree to all those things which the Thing defined agrees with.

XVIII. The Third, That the Definition consist of that which is more known: For seeing that a Definition is declarative of the Essence, it must therefore employ clearer Terms; lest we should be guilty of endeavouring to explain an unknown thing, by that which is more unknown, and so instead of attaining a clear and distinct Perception, should fall into Obscurity and Confusion.

XIX. The common Definition of time, that it is, The Number or Measure of Motion, cannot be good, seeing it is evident, or apparent, that Time doth as well Measure Rest, as Motion, since we say, as well that a thing hath rested so long, as that it hath been in Motion for that time.

The Seventh Rule.

Concerning the Judgment of Definition.

XIX.
The Se-
venth Rule.

That Definition is the most perfect and consummate of all others, which defines the Thing by its Essential Attributes, or constituent causes of its Nature and Essence.

As if one should define the Soul to be a Cogitating Substance, or a Body to be a Substance consisting of three Dimensions. Because Substance as the Genus doth constitute the Soul and Body; and Cogitation as the Difference, distinguisheth the Soul from the Body; As Extension in Length, Breadth and Depth, doth difference the Body from the Soul: Neither is there any thing else required to the understanding of them both.

The Third Part of Logick. Concerning the Minds Ratiocination, Syllogism.

CHAP. XV.

Of Reasoning or Argumentation.

I. What it is to Reason or Discourse

HAVING spoken of Ideas which represent Substance, and their Modes, and concerning the Judgment and Axioms which arise from their Connexion, it now remains to explain what Reasoning or Ratiocination is, or that Judgment, by which from one Axiom, another is gathered or inferred. For to Reason is nothing else than from a thing known to derive the Knowledge of another: And Reasoning is nothing else, than the Knowledge of one thing deduc'd from the Knowledge of another: As when a Man infers the Heaven to be extended, because all Bodies are extended. And therefore this Judgment is called *Dianoerick* or Discursive, because the Mind by it runs from one thing to another, and from the Antecedent is lead to the Consequent.

II. What it is that Argumentation superadds to Judgment.

Wherefore as Judgment, or the second Operation of the Mind, superadds to the first, which is Perception, Assertion, that is, Assent or Adhesion to Truth: So Ratiocination adds to them both, Deduction, Illation, &c.

III. What things are to be minded in Discourse.

In every Argumentation there are two Things chiefly to be minded, the Question it self, that is propounded, and the Argument or Reason that proves the same, or which confirms that which is doubtful, by those things that are certain and evident, and from the Question produceth an undoubted Conclusion. Accordingly in every Argumentation there are two things, that which infers, and that which is inferr'd; that which is gathered, and that from whence it is gathered, howsoever these parts may be disposed or exprest.

IV. Ratiocination contains two Parts.

Hence it is that every Argumentation consists of two Parts, viz. of an Antecedent and Consequent, or the Part inferring and that which is inferr'd. That goes before for the confirming of something else; this follows and is gathered from the former: As, when I say, *An Angel is Immaterial*; and therefore is Indivisible. For the first Part, viz. *An Angel is Immaterial*, is the Antecedent, and the other, *An Angel is Indivisible* is the Consequent: And the word *Therefore* is the Sign of the Inference, or formal Consecution.

V. The Pre-

It is requisite to the Notion of an Antecedent,

from which a certain Conclusion may be deduced; that it be better known and more evident to us; for otherwise it will not conduce to that which we would infer thence. For the Order of Science requires, that beginning from the Easiest things, we proceed by degrees to those which are more difficult to be known. Wherefore, to discourse readily, it is needful that we have ready at hand a Stock of many Axioms, Springing from the Complexion of the Things we have clearly and distinctly conceived; that may serve us instead of Principles, and by whose helps we may arrive to the knowledge of things more abstruse. For we must not promiscuously make use of any known and certain Propositions to infer any thing; but it is requisite that between them there be some Connexions by means whereof, this rather than any thing else may be gathered or inferr'd from it. Because there is a Consequence assigned to every Argumentation, yea a necessity of Consequence, which doth not only depend on the Order of Knowledge, but also on the Natural Connexion of the Things that are to be known.

All Argumentations have not the same force; for seeing that the Judgments of which they are compounded, have not the same Connexion, they must needs according to the variety of Propositions, produce various kinds of Reasoning. For Consequences that are deduc'd from Contingent Premisses, cannot have so great Truth and Certainty as those, which are inferr'd from Necessary Premisses, and which cannot be otherwise. By Example, this Proposition, *Sempronia Loves her Childeren*, deduced from this Antecedent, *every Mother Loves her Childeren*, differs from this, *Peter is an Animal*, which is deduced from this Antecedent, *A Man is an Animal*: Because the certainty we have that a Man is an Animal, is Metaphysical; Seeing we cannot conceive a Man any otherwise. And therefore this Proposition, *A Man is an Animal*, is so True, that it can never be false: Whereas the certainty we have, that Mothers Love their Childeren, is only Moral, since it can happen that some Women may not Love their Childeren.

An Argumentation in general, is a Speech wherein from certain Propositions expressly or tacitly premised, An other Proposition distinct from those premisses is necessarily inferred, by Reason of the due Disposition of them.

If there be just three Propositions in the Argumentation, The first is called the Major, because in it the Major Term is disposed with the Mean or Medium. And by some it is called only The Proposition, by way of Excellence, because it propounds the Foundation of the whole Argumentation.

The Second is called the Minor, in which the Minor Term is disposed with the Medium. It is by some called Assumption, because it is assum'd or taken in as a help, to infer the Third, or Conclusion.

The Third is called Conclusion, in which the Minor and Major Terms are disposed. And is by some termed the Question, because it contains that whose Truth was enquired after, as also the Inference or Consequence, because it is inferr'd and follows from what went before, and that by the illative Conjunction *Therefore*, &c.

The two first Propositions are called Premisses, because they must Precede the Conclusion, at least in our Conception, in as much as it necessarily follows from them; because it is impossible, supposing

misses may be more known than the Conclusion.

VI. Reasonings or Argumentations differs in Truth.

VII. The Definition of an Argumentation in general.

VIII. What the Major Proposition is.

IX. What the Minor is.

X. What the Conclusion is.

XI. The two Propositions must go before in every Argumentation.

the Truth of the Premises, that the Conclusion should not be true. Yet it is not necessary, that in every Argumentation the Premises should be expressed, since frequently one alone is sufficient, to make the Understanding, tho' somewhat confusedly, to conceive both. For he who from this Antecedent, *Every Stone is a Body*, deduceth this Consequence, *A Diamond is a Body*, had a confused Knowledge thereof in the Antecedent, where in it is implicitly contained. And he that from this Proposition, *A Body is a Substance*, infers that *A Diamond is a Substance*, by knowing it to be a Body, knows it to be a Substance.

XII.
In every Argumentation are found three Ideas.

Every Argumentation consists of three Ideas; the Minor Extremum, or Idea, which is the Subject of the Question, or Conclusion; and is also called the Minor Term; because the Subject is of less extent than the Predicat: The Major Extremum, or Idea, which is the Predicat, and which is also called the Major Term; because it is of larger extent than the Subject: And the Mean, or Medium, which is twice put in the Premises, and is that which joyns both Ideas together; as in this Argumentation:

*Every Intellectual Substance is Cognitive;
The Mind is an Intellectual Substance;
Therefore the Mind is Cognitive.*

Here Intellectual Substance is the Middle Term; Cognitive, the Major Extremum; and Mind, the Minor Extremum.

XIII.
Why there are three Ideas required in every Argumentation.

The Reason why these Three are required in every Argumentation is hinted by Aristotle, when he saith, That we meet with Three things in every Science, or Demonstration, viz. the Subject, of which the Attribute is demonstrated: The Property it self, or Attribute, which agrees with the Subject; and the Reason, or Principle, which makes out this Agreement of the Affection with the Subject. So that the Subject, of which the Demonstration is made, is the Less Extremum; the Attribute, or Affection, which is prov'd, the Greater Extremum; and the Common Term, wherewith the Subject and Attribute are joyned together, is the Argument, or Middle Term.

XIV.
The matter explained by an Example.

For Example: This Question is propounded to be explained, whether the Earth be Round; and the thing required is, That from the Doubtful Question a certain Conclusion be deduced: The Earth is the Subject or Minor Extremum; Roundness is the Affection, or Property, to be demonstrated; and I am to find out a Medium, by which it may appear that the Attribute agrees with the Subject. Which may be this: That the Shadow of the Earth, as appears in a Lunar Eclipse, is Round, for the Shadow intimates the figure of Opaque Bodies: From which accordingly this Syllogism may be framed.

A Body whose Shadow is round, must it self be round also.

*But the Earth is a Body, whose Shadow is round.
Therefore the Earth is round.*

XV.
Sometimes more than three Ideas are found in an Argumentation.

But notwithstanding that an Argumentation is made up of three Propositions, yet many more may be added to them, without any Redundance or Defect; as long as the Precepts of Ratiocination are but observed. For if the Third Idea, which we have taken to discern whether the Attribute agree with the Subject, or be removed from it, after having compared it with both the Ex-

trems, do not give us a clear discerning, whether it agree with it or no; we may assume another fourth Term, to procure a further clearness; and if that be not yet sufficient, may proceed to a fifth, until we come to some Term, which may joyn the Attribute of the Conclusion with the Subject of the Proposition. As if supposing a Man should doubt whether Courtiers be miserable, he may consider that Courtiers are subject to many Passions, as Ambition, Envy, &c. and if he thinks this not to be sufficient, to prove them to be miserable, he may further examine what it is to be subject to Ambition, Envy, &c. which if he does, he shall find that it is continually to hanker after Honour, to be grieved at the prosperity of others, &c. and that such a Condition as this cannot but be obnoxious to many Miseries; whence he may form this Argumentation: *Courtiers are tormented with Ambition and Envy, and they that are so, are in continual Trouble, and they that are in continual Trouble, are miserable. Therefore Courtiers are miserable.*

Argumentation in General, is divided into Perfect, and Imperfect. Perfect Argumentation is a Syllogism, which forasmuch as it consists of Three Propositions, duly disposed, is of a perfect Form, and most proper to persuade. An Imperfect Argumentation is; either an Enthymeme, an Induction, an Example, a Dilemma, or a Sorites, whose Form is less accurate, and not so accommodate to persuade as the Perfect. We shall first treat of a Syllogism, and afterwards proceed to the rest.

CHAP. XVI.
Of Simple Syllogisms; and those either Complex, or Incomplex.

OF SYLLOGISMS, some are Simple; Others are Conjunct. Simple Syllogisms are such, in which the Medium is only joyned to one Term of the Conclusion at once: Conjunct are those in which the Medium is at once joyned with both Extremes. Accordingly this Syllogism:

*Every Planet is enlightened by the Sun;
Saturn is a Planet;
Therefore Saturn is enlightened by the Sun.*

Is Simple, because the Medium, viz. Planet is separately joyned with the Term Saturn, which is the Subject of the Conclusion. But for the contrary Reason this Syllogism:

*If a Covetous man serves Mammon, he cannot obey the Law of God;
But a Covetous man serves Mammon;
Therefore a Covetous man cannot obey the Law of God.*

Is Conjunct, because a Covetous man, which is the Subject of the Conclusion, and cannot obey the Law of God, which is the Predicat, are both joyned with the Medium, serves Mammon, in the Major Proposition. Of this latter sort we shall speak in the next Chapter.

A Simple Syllogism is divided into two other kinds: For there are some, in which tho' the Conclusion be Complex, that is, composed of Complex Terms; yet one part only of its Subject or Predicat is taken, to be joyned with the Medium in one Proposition; and the rest, which is no more than one Term, is taken and joyned in the other Proposition: As in this Syllogism;

The

The Divine Law requires us, to honour Kings;
Charles the Second is a King;

Therefore the Divine Law requires us to honour
Charles the Second.

There be others again, in which each whole Term
of the Conclusion is joyned with the Medium; to
wit, the Attribute in the Major, and the Subject in
the Minor. The former are called *Complex*, the
latter *Incomplex*. And of these two kinds of *Simple
Syllogisms*, we shall speak under this Head.

III. The Definition of a Simple Syllogism, A *Simple Syllogism* therefore is a *Perfect Argumentation*, in which from two Propositions premised in the Antecedent, the Conclusion or Consequent necessarily follows, in case the two foregoing Propositions have been granted. I have said in the Definition, *That the Conclusion necessarily follows from the Premises*; because our assent to the *Premises* necessitates the *Conclusion*, not only as to *Species*, as they call it, but as to *Exercise*. For the Knowing Faculty acts necessarily, that is, supposing all Requisites necessary for Operation, cannot chuse but operate: But when the *Major* and *Minor* are granted, there is nothing more wanting to infer the *Conclusion*; therefore the Understanding cannot but infer it.

IV. The Understanding cannot but assent to a Proposition that is clear and evident, Neither is it any obstacle to what hath been said, that the *Understanding* is subject to the *Will*. For this is false, whenever the Object is evidently and distinctly propounded to it; because in that case it is forced to assent by the Evidence of of the thing. For we often experience in our selves, that the *Understanding* cannot be restrained from giving its assent to a *Proposition* which appears clear and manifest to it; tho' the *Will* may sometimes indirectly hinder it, by diverting it, and busying it about other Objects: But this it cannot do directly, by commanding it not to assent to the *Conclusion*; because the *Understanding* doth not follow the command of the *Will* in things that are Evident, but only in those that are obscure and doubtful.

V. The Form of a Syllogism, is the Regular disposition of the three Propositions, so that the *Conclusion* may necessarily follow from the *Premises*; which consists in this, that the Middle Term be fitly ranked with the two Extrems, that is, with the *Major* and *Minor*; and also that the *Propositions* be orderly placed, as to *Quantity*, that is, *Universality* and *Singularity*; and *Quality*, that is, *Affirmation* and *Negation*. The former of these, which is the Disposition of the Terms, is called *Figure*; the latter, which is the Determination of the Propositions, is called the *Mode* of a *Syllogism*. So that the *Figure* respects the remote Matter of a *Syllogism*, viz. the Three Terms, the Middle Term, and both Extrems; whereas the *Modus* regards the next Matter of a *Syllogism*, viz. the Three Propositions, the *Major*, *Minor*, and *Conclusion*.

VI. The three Figures of Syllogisms, There be three Figures of *Syllogisms*: The First is, when the Middle Term is the Subject in the *Major*, and the *Predicat* in the *Minor*. The Second, when the Middle Term is the *Predicat* in both Premises. The Third is, when the Middle Term is the Subject in them both.

VII. Of the Modes of Syllogisms, There are reckoned 21 Modes of *Syllogisms*, which may be reduced to 14. The Modes of the First Figure, are *Barbara*, *Celarent*, *Darii*, *Ferio*.

Of the Second, *Cesare*, *Camestres*, *Festino*, *Baroco*.

Of the Third; *Darapti*, *Felapton*, *Disamnis*, *Datisi*, *Bodardis*, *Terison*.

The Modes of the first Figure are called *Direct* and *Perfect*, because all manner of *Questions*, whether *Affirmative* or *Negative*, *Universal* or *Particular*, may be concluded by it. Whereas in the *Second*, *Negatives* only; and in the *Third*, *Particulars* only can be inferred. In all the foregoing *Artificial Words* there are Three Syllables, whereof the first signifies the *Major*, the second the *Minor*, and the third the *Conclusion*; and the Vowel of each Syllable shews what *Quantity* and *Quality* the Proposition must be of. For *A* signifies an *Universal* affirming; *E*, an *Universal* denying; *I*, a *Particular* affirming; and *O*, a *Particular* denying Proposition, according to the common Distick.

Afferit A, negat E, verum Generaliter ambo.
Afferit I, negat O, sed Particulariter ambo.

A affirms, E denies, but Generally both;

I affirms, O denies, but Specially both.

For the further clearing of the Figures of *Syllogisms*, I shall add Examples of the Modes of each Figure.

The First Figure.

Bar- Every Body is extended,
ba- Every Stone is a Body;
ra- Therefore every Stone is extended.

Ce- No Mode is a Substance,
la- Every Figure is a Mode;
rent- Therefore No Figure is a Substance.

Da- Every thing that is mov'd, is mov'd by
ri- Some Body is mov'd;
i- Therefore some Body is mov'd by another.

Fe- No Spirit is Material,
ri- Some Substance is a Spirit;
o- Therefore some Substance is not Material.

The force of the first Figure is grounded on the *Dictum de Omni*, and *Dictum de Nullo*. The *Dictum de Omni* is this: Whatsoever is *Universally* affirmed of an *Universal*, is also affirmed of that which is contained under that *Universal*: As of a *Body*, it is *universally* affirmed that it is *Extended*; which must therefore also be affirmed of a *Stone*, which is contained under it. *Dictum de Nullo* is, when whatsoever is *universally* deny'd of an *Universal*, is also deny'd of that that which is comprehended under that *Universal*: As when every *Substance* is deny'd to be a *Mode*, and *Figure* is contain'd under the Notion of a *Mode*; therefore *Figure* is denied to be a *Substance*.

Ce- No Stone is a Plant,
fa- Every Oak is a Plant;
re- Therefore no Oak is a Stone.

Ca- Every Body is divisible,
me- No Point is divisible;
stres- Therefore no Point is a Body.

Fe- No Impenitent person shall be saved,
sti- Some man shall be saved;
no- Therefore some man is not an Impenitent person.

VIII.
The first Figure.

IX.
On what Principles the first Figure is grounded.

X.
The second Figure.

Every

XI.
The third
Figure.

Ba- Every Universal is communicable to more
than one;
ro- Some Nature is not communicable to more
than one;
co- Therefore some Nature is not Universal.

The Third Figure.

Dar- Every Body is divisible;
ap- Every Body is a Substance;
ti- Therefore some Substance is divisible.
Fel- No Angel is circumscrib'd by place;
ap- Every Angel is Finite;
ton- Therefore something that is finite, is not
circumscrib'd by Place.

Di- Some Number may be increased;
sa- Every Number is an Affection of things;
mis- Therefore some Affection of things may be
increased.

Da- Every one that serves God is a King;
ti- Some one that serves God is poor;
fi- Therefore some one that is poor, is a King.
Bo- Some Folly is not to be blamed;
car- Every Folly is a defect of right Reason;
do- Therefore some defect of right Reason is
not to be blamed.

Fe- No heavy Body tends downward of its
own accord.
ri- Some heavy Body is Matter;
fon- Therefore some Matter doth not tend down-
ward of its own accord.

XII.
Galens
Fourth Fi-
gure.

The Fourth Figure is said to be Galen's, and is
when the Medium is predicated in the Major Pro-
position, and subjected in the Minor; which tho' it
concludes necessarily, yet (as Averroes saith) with
some Machination or difficulty, and besides Expe-
ctation.

General Rules of Syllogisms.

XIII.
The Rules
of Syllo-
gisms.

Forasmuch as all Conclusions cannot be deduced
from any Premisses: There are some Common
Rules, which are to be observed in all Syllogisms.

XIV.
The First.

The First is this, The Middle Term must be
distributed, that is, it cannot be twice taken par-
ticularly, but must once at least be taken generally.

For should the Medium be twice taken particu-
larly, as it must be when the Premisses are parti-
cular, it may be taken for divers parts of the same
Whole; because Particulars are distinct, and so
nothing will be concluded, or at least nothing
necessarily concluded. Which is sufficient to make
an Argumentation faulty, since that only is called
a good Syllogism, whose Conclusion, if the Premisses
be true, cannot be false. And therefore this Argument,

Some Body is Triangular,
Some Body is Spherical;
Therefore some Spherical Body is Triangular.

For since Body is taken here for divers parts of
Bodies, a Spherical cannot be joyned with a Trian-
gular; because the same Body which is Spherical,
cannot also be Triangular.

XV.
The Second
Rule.

The Second, From pure Negatives nothing can
be concluded. The Reason is, because two Nega-
tive Propositions separate the Subject from the Me-
dium, and the Attribute also: Now from the se-
paration of two things from the same Thing, it doth
not follow, that they are the same Thing, or that
they are not the same Thing. As for Example,

from these Propositions that the Mind, is not the
Body, and that the Body is not capable of Percep-
tion, it doth not follow, that the Mind is not capa-
ble of Perception.

The Third, The extremes of the Conclusion, must
not be more Universally taken, than they were
taken in the Premisses.

Wherefore when either of the Extreams is taken
Universally, the Argumentation must needs be false,
if it be taken particularly in the two first Proposi-
tions. The Reason of this Rule is deducible from
the first, because it is irregular to Argue from a
Particular, to an Universal. For from this, that some
Men are given to Drink Wine, it cannot be con-
cluded, that all Men are given to Drink Wine.

The Fourth, The Conclusion always follows the
weaker part of the Premisses. That is, if either of
the Premisses be Negative, the Conclusion must be
so also; and if either of the Premisses be Particu-
lar, the Conclusion must be Particular also.

The Reason of this Rule is, because where there
is a Negative Proposition in Syllogism, the Medium is
removed from one of the extremes of the Conclusion,
and therefore can never joyn them together, which
is required to make an Affirmative Conclusion;
and if either of the Propositions be particular, no
Universal Conclusion can be deduced from them.
For if the Universal Conclusion be Affirmative, the
Middle Term being Universal, must also in the
Assumption or Minor Proposition be Universal, and
therefore must be its Subject, since the Attribute,
in Affirmative Propositions, is never taken Uni-
versally; wherefore the Medium joyned to the Sub-
ject, will be particular in the Minor; and so the
Universal will be in the Major; for otherwise it
would be twice particular: And therefore it will
be the Subject, and therefore that Major, must
be likewise Universal. So that there can be no
particular Proposition in an Affirmative Argumen-
tation, whose Conclusion is Universal.

Of Complex Syllogisms.

From what hath been said, may easily be under-
stood what Complex Syllogisms are: For they are
not so called, because they consist of Compound Pro-
positions, but because the Terms of their Conclu-
sions are Complex, and are not taken entire in each
of the Premisses, in order to their being united
with the Medium, but only one part of their Terms:
As in this Example.

Gold is an Inanimate Thing,
Covetous Men worship Gold;
Therefore Covetous Men worship an Inanimate
Thing.

In which Syllogism the Attribute of the Conclusion
is, Worship an Inanimate Thing, whereof only some
part is put in the Major, viz. an Inanimate Thing,
and Worship in the Minor.

These Syllogisms in the Conversation and Dif-
courses of Men, are more frequent than Incomplex
ones, which are seldom or never used, except it be
in the Schools? For who ever in common Speech,
heard a Man Discourse at this rate: Every Stone is
a Body, A Diamond is a Stone; therefore a Dia-
mond is a Body. And tho' Complex Syllogisms
seem at the first sight, to deviate from the Rules of
Figures, yet they appear to be true, when they
are reduced to Incomplex ones. For this Syllogism,
The Scripture Commands us to Honour Kings.

Charles

Charles the Second is a King;
Therefore the Scripture Commands us to Honour
Charles the Second.

Tho' it be in the Second Figure, in which it is repugnant for all the Propositions to be Affirmative, yet it is for all that a true Syllogism, because in this Proposition, The Scripture Commands us to Honour Kings; the word Kings, is taken for all Kings in particular, and therefore Charles the Second is reckoned amongst them, that are to be Honour'd. Besides King, which is the Middle Term, is not the Attribute in this Enuntiation; the Scripture Commands us to Honour Kings, tho' it be united to the Attribute Commands. For that which truly is the Attribute, is affirmed and agrees: But King is neither affirmed, nor agrees, that is, it is not here annexed to Scripture, which is the Subject. Again, the Attribute is restrain'd by the Subject, but the term King, is not restrain'd in this Proposition; The Scripture Commands us to Honour Kings, because it is taken Universally. Wherefore we must say, that it is the Subject of another Proposition involved in it, as if I should say, The Scripture Commands that Kings be Honour'd. So that this whole Argument consists in these Propositions,

Kings are to be Honour'd,
Charles the Second is a King;
Therefore Charles the Second is to be Honour'd.

And therefore this Proposition, The Scripture Commands, which before was look'd upon as Principal, is only incident to this Argumentation, and is joyned to the Affirmation, to which the Scripture is added as a Proof. Whence it is manifest, that this Argument is of the first Figure, and in Barbara, because that Singulars are esteemed Universals, when they are made use of in their whole Latitude.

CHAP. XVII.

Of conjoynd or Compound Syllogisms.

I. **Conjoynd or Compound Syllogisms** are those in which the Major is so compounded, that it contains the whole Conclusion. And because the Major Proposition of such Syllogisms is four-fold, viz. Conditional, Copulative, Disjunctive and Proportional or Analogical, therefore they constitute four kind of Syllogisms, Conditional, Copulative, Disjunctive, and Analogical.

II. **Conditional Syllogisms** are those in which the Major Proposition is Conditional, and contains the whole Conclusion, As

If the Soul of Man be Corporeal, it may be divided into Parts,
But the Soul of Man cannot be divided into Parts,
Therefore it is not Corporeal.

The Major consists of two Propositions; the first is the Antecedent, If the Mind of Man be Corporeal; the second, the Consequent, it may be divided into Parts.

III. The Figure of Conditionals may be two-fold; the first is, when the Antecedent of the Major, or Principal Proposition, is put in the Minor or less Principal, so as that the Consequent of the same may be put into the Conclusion; as in this Syllogism:

If created things cannot subsist of themselves, it is necessary that they be preserved by God;

But created things, cannot subsist of themselves,
Therefore it is necessary that they be preserved by God.

And this sort of Argument is founded upon this Maxim; where the Antecedent is put the Consequent must be put also.

The other Figure is when the Consequence of the said Major Proposition, is taken away, that the Antecedent may be taken away also; As,

If John doth Marry this Woman, he is unwise,
But John is not unwise,
Therefore John doth not Marry this Woman.

This kind of Argumentation is founded on this Maxim; Where the Consequent is taken away, the Antecedent must be taken away likewise. Now to put the Antecedent or Consequent, is to Affirm that which is Affirm'd, and to Deny that which is Denied: And to take them away, is to Deny that which is Affirm'd, or Affirm that which is Denied. Or to speak more distinctly, to put, is to Affirm the Antecedent that hath been Affirm'd, or to Deny the Antecedent that hath been Denied; and on the contrary to remove, or take away, is to Deny the Affirm'd Consequent, or to Affirm the Denied Consequent. So that he also takes away that Affirms, that which was Denied before. As for Example, If an Angel hath not Organs, he doth not Feel: But he hath not Organs, Therefore he doth not Feel, Is a Syllogism deduced from the Position of the Antecedent, to the Position of the Consequent, notwithstanding that it proceed by way of Negation.

Conditional Arguments become faulty, these two manner of ways; the one is when from a true Major, a false Conclusion is deduced: As when the Antecedent is inferred from the Consequent: As if one should say,

If a Stone be a Living thing, it is a Substance,
But a Stone is a Substance,
Therefore it is a Living thing.

And another way, when from the Negation of the Antecedent, is inferred, the Negation of the Consequent, As in the same Example,
If a Stone be a Living thing, it is a Substance,
But a Stone is not a Living thing,
Therefore it is not a Substance.

Copulative Syllogisms are only of one sort, as when in a Copulative Proposition Negative, one part is put, to take away, or remove the other: As,

The same Body cannot be at the same time, both Round and Plain;
But the Earth is Round,
Therefore it is not Plain.

Because these Syllogisms do not necessarily conclude, when one part is taken away, and the other is put in its place; as appears in this Argument, taken from the same Proposition.

The same Body cannot be both Plain and Round,
But the Earth is not Round,
Therefore it is Plain.

Disjunctive Syllogisms are such whose first Proposition is Disjunctive, that is, whose Parts are joyned with the Disjunctive, or, either.

Death happens to Man either by default of the Soul, or of the Body;

L

But

But it doth not happen by default of the Soul,
Therefore by default of the Body.

IX.
Their Fi-
gure is
twofold.

The Figure of Disjunctive Syllogisms is two-
fold; the one, when one part is taken away, that
the other may be put; as in the Example before
alledg'd: The other, when one part is put, that the
other may be taken away: As,

*They who first gave us an account of Antipodes,
either spoke the Truth, or imposed upon us;
But they spoke the Truth,
Therefore they did not impose upon us.*

A Disjunctive Syllogism is grounded on this Prin-
ciple, that two Contradictions cannot be true at the
same time. Wherefore it is necessary, that the
Parts of a Disjunctive Proposition must be Repug-
nant, so as that when one is put, the other is remov'd;
and when one is remov'd, the other is put, as in the
alledged Examples. When it happens, that there
be more Parts of the Disjunction than two, one of
them must be oppos'd to all the rest; as if one
should make this Proposition:

*It is neither Winter, nor Summer, nor Spring, nor
Autumn,*

One part only must be put in the Assumption or Mi-
nor Proposition; that so in the Conclusion, the rest
may be taken away; As thus,

*It is Winter, therefore it is neither Summer, nor
Spring, nor Autumn,*

Or else the rest must be taken away in the Assump-
tion, that one Member may be put in the Conclu-
sion; thus,

*It is neither Summer, nor Spring, nor Autumn,
therefore it is Winter.*

X.
How Ana-
logical Syl-
logisms are
formed.

To these we may add Proportional or Analogi-
cal Syllogisms, in which the Analogy and Propor-
tion is dilated, or Adjuncts are explained. For Pro-
portions here spoken of is nothing else, than the
agreement of Relatives. As when from four Rela-
tives; as for Example, four Numbers, 2, 4, 3, 6,
we say that the same is the Relation of the half,
and double, between 2 and 4, as between 3 and 6.
Or when in a Triangular Figure, considering the
two Angles of it, and the two opposit Sides; we
assert the Relation of Equality and Inequality to be
the same, as there is between Side and Side. The
First and Third, are by Geometricians commonly
called Antecedents, as the Second and Fourth Con-
sequents, because they follow from the former.

XI.
What Ana-
logical Syl-
logisms are.

SYLLOGISMS are called Proportional or
Analogical, when the Proportion set down in the
Major Proposition, is protracted, or dilated: Which
then happens, when the Consequents in the Minor,
being taken for Antecedents, are further referred to
other Consequents: And then conclude, that there
is alike Proportion between the first Antecedents, as
between the latter Consequents. As when we say,
2 are to 4, as 3 are to 6, and 4 are to 8, as 6 to 12.
Therefore 2 are to 8, as 3 to 12. Because in this
way of Discourse, it is made clear, that 4 and 6,
which are the Consequents in the Major Proposi-
tion, are made the Antecedents in the Minor: And
because the Relates are the Middle Terms, to which
the Extreams (viz. the Antecedents and Conse-
quents) are joyned, therefore we infer, that the Ex-
treams themselves, agree also. And such Syllo-
gisms as these, are said to conclude equally; foras-
much as in them, both the Relations as they begin

in the same manner, so likewise they proceed and
end, in the same manner.

Analogical Syllogisms are also formed in this XII.
manner, when after that a like Proportion hath The Second
been set down in the Major Proposition, an Adjunct way of
is taken up in the Minor, by which the Proportion forming
is rendred more evident, which therefore so agrees Proportio-
to one Antecedent, with respect to its Consequent, nal Syllo-
that thence we conclude, that it also agrees with gisms.
another Antecedent, with respect to its Consequent.
For if one should call at Pleasure two Sides of a
Triangle, A, B, and the two opposit Angles, C, D,
and then argue thus: The Side A is to the Side B,
as is the Angle C to the Angle D; but the Angle
C is greater than the Angle D; therefore the Side
A is greater than the Side B. For by this Term
Greater, it is clearly explained wherein the Pro-
portion consists.

Thirdly, Proportional Syllogisms are made by the XIII.
Commutation of Proportions; viz. when a Propor- The Third
tion being set down in a like manner in the way.
Major Proposition, the Minor is pass'd by in Silence,
and the Relates are so inverted, that they are mu-
tually concluded of each other. This way of Ar-
guing is often used by Geometricians, and more
especially by Arithmeticians: As when they reason
thus; There is the same Proportion betwixt 2
and 4, as betwixt 3 and 6, and therefore 4 are
to 2, as 6 are to 3; because that Maxim is impli-
cantly understood, that Like things agree with their
Like reciprocally.

CHAP. XVIII.

Of Imperfect Argumentations.

SOME Argumentations are called Imperfect, I.
not with respect to the Matter whereof they What Im-
are compos'd; but with regard to the Form, perfect
which is not so exact in them, but less digested than Argumen-
that of a Syllogism. For in these the Antecedent tations are
consists expressly but of One Proposition, or of
Many: Such are Enthymeme, Induction, Example,
Sorites, and Dilemma.

An ENTHYMEME seems to have taken its II.
Name from this, that it expresseth only One Propo- What an
sition, and suppresseth the other, as being too clear Enth-
and obvious, and which is easily understood by ymeme
those we discourse with. This way of Arguing is
very common among Men, who in their usual
Reasoning commonly suppress the Proposition, as
supposing that they to whom they speak will easily
supply it: As when we say,

I was able to save thee,

And therefore also to ruin thee.

In which Argumentation there is only one of the
Premisses express'd, and the other suppress'd or
imply'd, which when added it affords this Perfect
Syllogism.

*Whoever was able to save thee, was also able
to ruin thee;*

But I was able to save thee,

Therefore I was also able to ruin thee.

INDUCTION is an Argumentation, which III.
from many Singulars concludes an Universal Induction.
As,

*This Triangular consists of three Lines, and so
doth that likewise, and all the rest; therefore every
Triangle consists of three Lines.*

To

To this way of Reasoning it is required, that it contain an enumeration of all the *Species and Parts*; for if but one be wanting, it admits of an Exception, and subverts the whole *Proposition*. Wherefore nothing can certainly be proved by *Induction*, except the same be whole and compleat in all its Parts, and so General, as to admit no Exception, which is very difficult, and almost impossible. For who can recollect in his Mind all the Cases of *Law*? or what Student of Natural Philosophy, can reckon up all the several kinds of *Bodies*, all *Plants*, *Animals*, *Stars*, &c.? Are not almost all Men of Opinion, that *Heat* dilates, and *Cold* contracts? Yet when we search more narrowly into the matter, we find that when *Water* is frozen, it takes up more space than when it is not frozen? Wherefore in cases where the greatest part of Particulars is only known, we can infer no more but thus; that for the most part it is so: Tho' sometimes we meet with some Special Cases, which swerve from the Common Rule. So from many Experiments we conclude, *Snow* to be *white*, a *Crow* *black*, and *Honey* *sweet*; notwithstanding that in some Countries there be found *red Snow*, *white Crows*, and *bitter Honey*.

IV.
What Example is.

EXAMPLE is a kind of *Imperfect Argumentation*, whereby from one *Singular* we gather another, because of a likeness of Reason that is between them. As when from this, That *Cæsar* subdued the People of *Rome* more by his *Clemency*, than by his *Arms*; I gather, that a Prince ought rather to have recourse to *Clemency*, than to *Arms*, for the reducing of his Subjects. Or when considering that others, by serious Meditation have arrived to some degree of Learning; I infer, that I my self also may arrive at the same by closely following my Studies, and by an attentive Consideration of the Things I undertake to examine.

V.
Argument from Authority.

To an Example belongs that which is called an *Argument from Authority*; which is, when we make use of the Testimony of one or more, to infer a Conclusion; whose force depends of a concealed, but yet imply'd *Proposition*: As when a Man saith, *Archimedes*, and other famous *Mathematicians* assert, that the *Sun* is many times bigger than the *Earth*: Therefore we ought to hold the *Sun* to be many times greater than the *Earth*. For here this *Proposition* is understood, That every man ought to be believed in his own Art and Profession: Or we are to take that for Truth, which *Archimedes*, and the most Learned *Mathematicians* do assert of their own Art.

VI.
Sorites.

SORITES, is an *Argumentation* consisting of many *Propositions* so disposed, that the *Predicat* of the foregoing *Proposition* becomes the *Subject* of the following; whence the last *Predicat* is in the Conclusion attributed to the first *Subject*. As in this Example, *Covetous persons* desire many things, *They who desire many things* want many things, *They who want many things* are miserable; therefore *Covetous men* are miserable.

VII.
When a Sorites doth not conclude truly.

This Argument doth not conclude truly, but when whatsoever is said of the *Attribute*, is likewise said of the *Subject*: Wherefore this *Ratiocination*, *Salt-meat* excites to drink, and by drinking *Thirst* is extinguish'd; therefore *Salt-meat* extinguisheth *Thirst*, is faulty: Because *Salt-meat* only by Accident invites Men to drink, forasmuch as it eaves a dryness in the Throat, which causeth drinking.

A DILEMMA is made by the *Disjunction* of many *Propositions* opposite to one another, whereby the Answerer is so shut up, that there is no way left for him to avoid the dint of it, which part soever he chooseth: As suppose a Man should accuse another of a Crime he hath committed, thus; *Either you did know your self to have offended against the King, or not; if you did know it, how durst you violate the Law of Majesty? If you did not, why did you run away?*

A Dilemma may be faulty two manner of ways: IX. One, when the *Disjunctive Proposition* wherein it is founded doth not contain all the parts of the thing divided: As if a man would prove, That one ought not to Marry, by this way of Arguing; *If you marry a Wife, she will be either Beautiful or Deformed; if Beautiful, she will make you Jealous; if Deformed, you will loath her; therefore you ought not to marry at all.* The Mistake is, because there are *Women* who neither are so Beautiful, as to cause Jealousie; nor so Deformed, as to cause Loathing.

In the Second place, a Dilemma is vicious, when the particular Conclusions of either part are not necessary: Thus it doth not follow that a *Beautiful Wife* must needs make her *Husband* Jealous, forasmuch as she may be so Prudent and Chaste, as not to give the least occasion to doubt of her Vertue. Neither is it necessary that a *Deformed Wife* should be displeasing to her *Husband*, because her Deformity may be made up by her Vertue and Ingenuity, which may render her very grateful to her *Husband*.

He that makes use of a Dilemma, must take care that it be such as may not be retorted upon himself, which it is said *Protagoras* did; to whom *Euathlus*, his Disciple, having promised a certain Sum of Money in consideration of his instructing of him, to be paid on that Day when he should first get the better in the Cause he pleaded; and taking that for his first Cause, to plead whether he was to pay that Sum of Money he had promised him, made use of this Dilemma: *Either I shall lose this Cause, or I shall win it: If I lose the Cause, then according to our Agreement, I am to pay you nothing; if I win it, then I shall owe you nothing by the Sentence of the Judges.* Which Argument *Protagoras* thus retorted; *Either you will lose this Cause, or win it: If you lose it, you will by Sentence be obliged to pay me; if you win it, you must pay me according to the Tenour of our Agreement.*

CHAP. XIX.

Of Demonstration, a Topical Syllogism and Sophistical.

FOR the better understanding of the following Discourse of *Apodictical*, *Topical*, and *Sophistical Syllogisms*, it is necessary that we first explain the Nature of *Science*, *Opinion*, *Error*, and *Faith*; that by exhibiting their distinct Notions, the Principles from whence they are derived may be the better known.

SCIENCE is the certain and evident knowledge we have of any thing: For whatsoever is so evident to us, that we are certain of it, that we are said to know, or have the Science of. Accordingly the knowledge of a Conclusion is certain and evident,

dent, when the *Premisses*, whereon as *Principles* it doth depend, are so.

III. *OPINION*, is a Knowledge that is not altogether certain, but joyned with some fear or wavering of the Intellect, in its assent to it. For *Opinion*, tho' it be a true assent to the Conclusion, yet is it doubtful and uncertain; and such an assent as this is the Effect of a *Dialectical Syllogism*, as *Science* is the Effect of a *Demonstrative*, or *Apo-dictical Syllogism*.

IV. *ERROR* is an Opinion opposite to *Truth*, that is, a False one.

V. *FAITH* is a Persuasion founded upon the Testimony of another, which may be either true or doubtful, according to the different Authority it rests upon. So the *Faith* we have to God is most firm and stable, because we know him to be True, and that to Lye is repugnant to his Nature. But the *Faith* we have to a Man, hath always something of Uncertainty joyned with it; since there is no man but can deceive another, if he please.

VI. If in considering any *Axiom*, the truth of it do immediately appear to us, from the Evidence that is found in it, without any further Proof or Disquisition, this kind of Knowledge we call *INTELLIGENCE*: And thus we know first *Principles*. But if by its own proper Evidence, it cannot engage the *Understanding* to assent, then we must have recourse to other Motives, by which the Intellect may be convinced of its Truth: Now these Motives can be no other, but *Reason* and *Authority*. If *Authority* engageth us to assent to the things Propounded to us, this is that we call *Faith*: But if *Reason* sways us, then either that *Reason* leaves some fear behind it, whereby we are made doubtful of the certainty of the thing, and then this assent is called *Opinion*: Or the *Reason* doth satisfy fully the *Understanding*, and then it is either *Seemingly* only Evident, for want of due Attention, and thence comes *Error* in case it be really false; or at least a *Rash Judgment*, if we take it to be true, before we have sufficient grounds of giving our Assent to it: Or if the *Reason* proposed to us, be not only seemingly true, but evidently so, and be clearly and distinctly perceived by our *Understanding*, then the Conviction produced in our Mind by this *Reason*, is called *Science*.

Forasmuch therefore as *Demonstration* begets *Science*, and that the Conclusion of a *Demonstration* is *Science*, we will first Treat of it, and afterwards in order, of those things that produce *Opinion* and *Error*.

VII. *DEMONSTRATION* is a *Syllogism* consisting of *Premisses* that are True, Immediate, Prior, more known and causes of the Conclusion. Those *Propositions* are said to be True and Immediate, which have their Evidence from themselves, and not from any other thing: And which are known by their Terms: As, *Every thing is, or is not*. For there is an Inborn Power or faculty in us, whereby we assent to first *Principles*. Wherefore we should never give our assent to the Conclusion, except the *Premisses* appeared evident to us; neither do we assent to the Conclusion, but because we believe the *Premisses* to be true; and therefore it is necessary that the *Premisses*, be more known than the Conclusion, according to that saying; *That for which any thing is such, is more such it self*.

VIII. *Demonstration* is twofold, the one *a Priori*, and

the other *a Posteriori*. *Demonstration a Priori* is twofold (which alone, to speak properly, is *Demonstration*) is that in which the Effect is Demonstrated by its Cause: As when we prove the Existence of Light, by the Existence of the Sun. Or when Geometricians prove that round Wounds are longer a Healing, than such as are of a long Figure, forasmuch as in those, the Sides are further distant than in these.

Demonstration a Posteriori is when we Demonstrate the Cause by the Effect: As when from the Existence of Light, we Demonstrate the Existence of the Sun. When we prove the Heaven to be stirr'd, or Fluid and Corruptible, from the various Things that are Generated in it; as from the Comets that are found in it; from the Spots about the Sun, and from many Stars, which for some time shew themselves there. To this kind of *Demonstration* may also be reduced the *Demonstration* which is made from the remote Cause, as when one proves that a Stone doth not breath, because it is not an Animal, when it would have been more proper to have proved it by this, because it hath no Lungs. For the having of Lungs is the near cause of Respiration, and not the being an Animal; nay it will be found that to have Lungs is not the property of an Animal, since there are many Animals that have no Lungs, as Oysters, &c.

Antient Authors make mention of another kind of *Demonstration*, which they call *Offensive*, by which a thing is Demonstrated from proper Principles, directly and by it self. As if a Man, when a right Line is given, and a Semidiameter made of two Circles, and two other right Lines, to one of the Intersections of the Circles, drawn from their Extrems, and by these three Lines a Triangle is made, should prove *Offensively* that this Triangle is Equilateral, or hath all its Sides alike, by shewing that the two last Lines are even, or of the same Length, because they are equal to the same Line given; and that they are equal to the same Line given, because both of them separately proceed from the same Center, to the same Circumference with it.

To this they have added another kind of *Demonstration*, which they call *Deductive to an inconvenient*; which tho' it be inferior to the former, yet may be of use, where we cannot have an *Offensive Demonstration*, as being also of insuperable necessity. And this is when we demonstrate a thing to be so, because if it should be otherwise, either an Absurdity, or an Impossibility, or a contradiction must necessarily be granted: Such as is, *That the Effect doth not depend on the Cause*; And *that the thing containing is less, than the thing contained*, and the like. As if by Deduction to an inconvenient he would prove the abovesaid Proposition from hence, because no Side can be admitted to be equal to another; but at the same time it must be granted, that all Lines drawn from the Center to the Circumference are equal; or that two things which are equal to one thing, are not equal between themselves.

A TOPICAL SYLLOGISM, which is also called *Suasory*, or *Opinable*, is that which concludes from Probables: Or whose *Premisses* do not hold forth, a necessary Connexion of the Subject, with the Middle Term, or of the Middle Term with the Attribute. For tho' the Conclusion it proves, partaks more of Evidence than Obscurity, yet it leaves something of doubt or Hesitation behind

hind it, which makes that the understanding cannot assent without some Scruple. And therefore it is commonly said that a *Topical Syllogism* doth persuade indeed, but doth not force one to assent as a *Demonstration* doth.

XIII. *What things are called probable.* Those things are called *Probable*, which seem to be so to all, or to the most, or to the Wise, or at least to the most, or most considerable amongst them: As it seems *Probable* to all, that the approaching *Summer* will be *Hot*, yet it is not certain, forasmuch as it sometime happens that the *Summer* is very *Cold*. It appears to most, that *Physick* is necessary for the Curing of *Diseases*, whereas, notwithstanding it often happens, either through the Ignorance of the *Physitian*, or through Default of the *Patient*, the Distemperature of the Air, or the Unhealthfulness of the Place, that a *Medicin* may do more hurt than good. It appears to *Wise Men*, that *Learning* ought to be desired by all; when notwithstanding there be many found that despise it, and who prefer their Ignorance before *Learning*. The most considerable Men, are of Opinion that the *Earth* is moved, and that the *Sun* stands still in the midst, and yet there are many that oppose this Opinion, and maintain the contrary.

XIV. *How a Topical Syllogism is distinguished from all others.* Wherefore all those *Syllogisms*, whose *Premises* are *Contingent*, and do not infer a necessary Connexion between the *Subject*, and the *Middle Term*; or between the *Middle Term*, and the *Predicate*, are called *Topical*, that is, *Local* or *Probable*. The former from the *Places* whence their *Proofs* are taken, the latter from the likelihood of them.

XV. *What a Sophistical Syllogism is.* A *SOPHISTICAL* or *Paralogistical Syllogism*, which with one Word is called a *Sophism*, is a *Syllogism* consisting of false *Propositions*, which yet have an appearance of *Truth*: Or is a *Syllogism*, that begets Error. As for Example, this *Syllogism*,

All Lines drawn from one Point to another are Equal;

But a Right and a Crooked Line, may be drawn from the same Point, to the same Point;

Therefore a Right and a Crooked Line are Equal.

XVI. *Of the various ways of deception in Sophistical Syllogisms; and first of the Fallacy in Words.* All *Fallacy* or *Deception*, is either in the very Form of the *Argument*, or in the Words, or in the Things. As to the Form of *Argumentation*, we have already largely Treated, in Chapter XVI. As for the *Cavilling* which consists in Words, that is called *Fallacia Dictionis*, or *Fallacy in Words*, which frequently consist in the Homonymy of the Words, when things altogether different are signified with the same Word. Sometimes also in the Ambiguous context of the Speech, and then it is called *Amphibology*; Examples of which kind, do also occur amongst the best of Authors.

XVII. *The Fallacy from conjoyned Things, to those that are divided; from a conjoyned Sense to a divided, and on the contrary.* There is another *Sophistical* way of Arguing, and on the other Hand, from Things divided to those that are conjoyned. This hath given occasion, to that Distinction of a Divided and a Compound Sense. The former is, when a *Faculty* or *Power* is joyned with an opposite Act; as the *Faculty* of *Laughing*, with the Act of *Weeping*; for this Proposition, he that *Weeps* can *Laugh*, is true in a Divided, though not in a Compound Sense. But a Compound Sense is, when two opposite Acts are

united together; and thus, this Proposition, *He that Laughs cannot Weep*, is true in a Compound, Though not in a Divided Sense.

There is a Third way of *Cavilling*, when we Argue from Second intentions, to First; as thus; *The Fallacy A Circle is a Figure; But Figure is a Genus, therefore a Circle is a Genus.* XVIII.

The Fourth is a *Dicto secundum quid*, from a Relative Expression, ad *Dictum simpliciter*, to an absolute Expression; As if a Man should Argue, that because *Blackamoors* are *White*, with respect to their *Teeth*, therefore they are absolutely *White*; or because *Wine* is for the most part Hurtful to Sick Persons, should conclude *Wine* to be absolutely Hurtful.

The Fifth is that which is called *Ignoratio Elenchi*, or Ignorance of the matter in Question, which is, when another thing is proved, than that which is denied by the Adversary.

The Sixth is *Petition* of the Principle, when the Point indispute is taken for granted. As if one should go about to prove that the *Earth* doth rest, because the *Sun* is moved: that being the Principal thing in Question, whether the *Sun* be moved.

The Seventh is taken a *Non Causa ad Causam*, from a No Cause to the Cause, as when that is brought in for a Cause, which is no Cause at all: As when we refer the changes of times to the Moon.

The Eighth way of *Cavilling*, proceeds from a manifold Question, which is, when many Questions are so Propounded, that they look like one only. As if one should ask, whether the *Sun* and *Earth* are moved.

There is no safer way to avoid these Captious *Sophisms*, than to define the Words themselves, in case of a *Fallacy* from *Equivocation*, or *Homonymy*. Neither are we only diligently to consider, what the thing in Question is, but also, what is the Attribute of the Question, and what Relation and Order it hath to the Subject it self. For it is of great importance, whether the Attribute be Universally by it self, and primarily Attributed to every Subject, or that it agree to some one only, or by Accident. In like manner, whether the Attribute be spoken of the Subject simply, that is, absolutely, or with respect to something: All which particulars may be easily known, from what hath been already said.

The Places from whence the Middle Term is Fetch'd.

We come now to the General Heads, or as the Rhetoricians call them, *Places of Arguments*, to which the *Proofs* which we use in any matter, may be reduced. For as some *Syllogisms* are *Demonstrative*, others *Opinable* or *Opinionative* and *Suasory*, and others again *Paralogistical* or *Erroneous*, so fetch'd, there must be divers Places, whence the Middle Term or Argument may be Fetch'd.

For in a *Demonstrative Syllogism*, the Middle Term agrees with the Subject, and the Attribute with the Middle Term, as a Genus, or a Propriety, or a Definition, or a Cause acting necessarily, and the like. As if a Man should have a Mind to Demonstrate that a *Mote* in the *Sun*, is indefinitely divisible, he may take the Genus for his Middle Term, and argue thus: A *Mote* is a *Body*, but a *Body* is indefinitely divisible, therefore a *Mote* is indefinitely

finitely divisible: The Minor is to be supposed from Natural Philosophy.

XXVII. Or a Propriety. So to demonstrate a Mans being Rational, we may take his Property, which is the Faculty of Speaking, and Reason thus: The Power of Speaking, that is, the Faculty of expressing ones Mind by Words, Signs, or Gestures, belongs to Man; But whatsoever enjoys this Faculty doth partake of Reason; therefore Man doth partake of Reason.

XXVIII. Or a Definition. So likewise a Definition may serve for a Middle Term, to prove that Oysters are Animals, thus: Oysters are Bodily things, endued with life and motion: But whatsoever hath life and motion is an Animal; therefore Oysters are Animals.

XXIX. Or a Cause. And so also a Cause acting necessarily, may be the Middle Term; for thus a Lunar Eclipse may be proved from its Efficient Cause, viz. the Sun and Moon being placed in opposite Nodes, or in the Intersections of their Orbs, after this manner: It is necessary for the Moon to be Eclipsed, as often as the Globe of the Earth interposeth between the Moon and the Sun, from which the Moon borrows her Light; but then the Globe of the Earth interposeth between the Moon and the Sun, when the Sun and Moon are in opposite Nodes; (because at that time they are Diametrically opposite, and the Earth plac'd in their Diameter) therefore there must necessarily be an Eclipse of the Moon, when the Sun and Moon are constituted in their Nodes, or the opposite intersection of their Orbs.

XXX. The Middle Term in a probable Syllogism may be fetch'd first from the Genus. We make use also of like places in a Probable or Suasory Syllogism; yet so as that tho' the Middle Term agree to the Subject, (yet the Attribute does not to the Middle Term, as a Genus, Propriety, &c. as before :) As if a Man to prove Rhetorick to be profitable for Mankind, should argue thus; Rhetorick is an Art, but every Art is profitable to Mankind; therefore Rhetorick is profitable to Mankind. In which Syllogism, the Middle Term Art, is indeed the Genus of the Subject Rhetorick; but the Attribute is profitable, is not its Genus, but only a contingent Adjunct, or common Quality; and therefore neither doth the Mind assent to it without something of Doubtfulness, whether or no Rhetorick may not be reckon'd amongst those Arts, which tho' they be accounted Subtil, yet are esteem'd by some as unprofitable, or at least indifferent.

XXXI. From a Propriety. In like manner one may prove, from a Propriety of Logick, that Logick is a thing desirable, thus: It is the Property of Logick, to direct the Mind in the knowledge of things; but what directs the Mind in the Knowledge of things, is something desirable; therefore Logick is a thing desirable. This Argument also leaves some hesitation in the Mind, because the directing of the Mind in the Knowledge of Things, doth not necessarily conclude the thing to be desirable; because there are many who rather desire to continue in their Ignorance, than to be instructed in Logick.

XXXII. From the Cause. We may also argue from the Cause thus: This Picture is drawn by Apelles; but the Pictures drawn by Apelles are very exact: Therefore this is an exact Picture. Which enforceth only a Probable, but not a certain Conclusion; because the best Painters do not always Paint alike, nor so exactly, but that sometimes Faults may be spied in their Works.

A Paralogistical, or Sophistical Syllogism, has but one only place, viz. Ambiguity; which being once detected, its Imposture lies open; and that which seem'd to be a good Syllogism appears to be none at all. Because the Reason of Syllogism requires, that it have only one Middle Term, one Subject, and one Attribute; whereas in a Sophistical Syllogism there are two Subjects, and as many Attributes without a Middle Term: As when a man Argues, some Mountain is Taurus, Taurus is a Lowing Animal: Therefore some Mountain is a Lowing Animal. For the Ambiguity here lies in the word Taurus, which agreeing to two different things, is in the Major taken for a Mountain, and in the Minor for a Four-footed Animal. Whence it appears, that the word Taurus is no Middle Term, forasmuch as it doth not agree with the Subject and Predicate.

For Ambiguity is that which occasions deception in all things; for he that concludes, that a Man asleep is awake, because it hath been before granted, that it is possible for a man that sleeps to be awake, doth not do it for any other Reason, but because this Proposition may be understood either disjunctly, with respect to different times; or conjunctly, with regard to the same time. And he who concludes that the Buyer hath eaten raw flesh, because it may be, he confess'd that he had eaten what he had bought, doth so because of the Ambiguity of the words, What he had bought; which may either be taken only for the substance of the Flesh; or also for an Accident of it, viz. Rawness. And the like may be said of all Sophistical Places, Amphibology, Composition, Division, Account, &c. forasmuch as they all agree in this, that they have some Ambiguity either in a Word, or in a Phrase; or that one Sense is taken in the Proposition, and another in the Assumption. So that it is no wonder, that when both are admitted for True, an Absurdity follows from them.

The Fourth Part of Logick. Concerning Method, or the Orderly Disposition of our Thoughts.

CHAP. XX.

Of the General Method of Knowing.

FORASMUCH as LOGICK was found out for the attaining of Sciences, and that our Thoughts can hardly be rightly formed without its assistance, METHOD seems to be necessary to assist and accomplish our Mind in the Knowledge of Things. For tho' possibly there may be some of such quick and piercing Wits, as without difficulty to dive into the Natures of Things, and to solve the most abstruse Questions; yet will he never be able to attain certain Knowledge, except he be first acquainted how he must direct his Mind, and what Order he must observe. Wherefore Method is necessary, as well to assist him in the searching out of Truth, as in the avoiding of Error, Confusion, and Obscurity. Which Method is nothing else, but an Orderly disposition of things to be treated of, suitable and accommodate to the Capacity of Learners. For it must

must be of that Nature, as not to put any force upon the *Wit* of Man, but rather pleasantly allure it, and guide and direct it by the Evidence and Easiness of its *Rules* and *Precepts*.

II. Three things are requisite to the manner of Knowing.

This Mode or manner of *Knowing* consists in Three things: *First*, That the thing propounded may be clearly and distinctly Perceived. *Secondly*, That we judge rightly concerning the Matters we have thus clearly and distinctly perceived. *Thirdly*, That we commit to Memory the *Truths* we have discover'd, that is, the things we have rightly Perceived and Judged. By observing these Three *Precepts*, we shall relieve all the Weaknesses of our Mind, and prevent those *Errors* into which it is apt to fall. For seeing that the main Obstacles of *Science* are, either an *over-hastiness* of the Mind; the same will be removed by clear and distinct Perception; or else *Error* and *Doubt*, which will be cured by Sound Judgment; or lastly, *Forgetfulness*, which will be prevented by the Remembrance of the Things perceived and judg'd by us. It remains only to enquire, by what means this *distinct Knowledge* may be attained; and how our Mind may be brought to that pass, as never to assent to any thing which it has not before clearly perceived, and so to impress the Things she has judg'd of in her Memory, that she may never forget them.

III. First, the distinct Perception of the thing.

As to the First, it is requisite, that setting aside all *Precipitancy*, we give heed to the Matter propounded, and (as it were) scan the same with our inward Eyes. In order to which, it will be proper for us to behold or contemplate one thing only at once, that our Understanding may not be distracted by the multitude of *Objects*, and left by minding many things, our attention to Particulars may be the less. For the multiplicity of *Objects* presented to our Understanding, breeds Confusion; and as they who behold a Field, distinguish'd with variety of *Colours*, do not distinctly perceive the variety of *Colours* that is in it, but behold it under the appearance of one Colour only: So they who consider several *Objects* at once, cannot bestow a due attention upon every particular; and it cannot otherwise be, but that they must be promiscuously confounded in their Mind.

IV. Wherefore we must rather set our selves to examine Simple things, than those that are Compound.

In order to attain this due *Attention*, it will be of good use to undertake the examining of a *Simple thing*, or of some *Attribute* or *Mode*: For these kind of Perceptions, whereby Simple and Incomplex things are represented to us, are more clear and distinct. As for Example, The *Soul* of Man is more distinctly perceived by us than *Man*; because the *Soul* of Man imports one Nature only, viz. a *Thinking Being*; whereas a *Man* comprehends two Natures, viz. a *Soul* and *Body*, which belong to two different *Genera*, and therefore cannot be both at once propos'd to the *Intellect* without some confusion.

V. Things Simple are to be examin'd before those that are Compound.

Accordingly *Simple things* are to be known before *Compound*, near before remote, and few before many. Thus we attain a fuller knowledge of the things that are born, if we begin the consideration of them from their first beginning. By which means the Famous *Harvey* perspicuously discovers the *generation* and *growth* of a *Chicken*, by shewing what Parts are daily formed in an *Egg*, which an *Hen* hatches. In like manner we arrive to a more accurate knowledge of a *Plant*, when we take a view of its *beginning*, *progress*, and *per-*

fection, considering it in its distinct Stages of its *budding*, *growth*, *blooming*, and *bringing forth fruit*; and the same may be said of all things that grow and increase.

But forasmuch as *Substances* are chiefly known by their *Attributes*, and that many of them are found in every *Substance*, we are rather to consider those that are *Positive*, than the *Negative*. Thus the Nature of the *Soul* is more easily known by me, when I consider it as an *understanding*, *willing*, and *judging Subject*, than when I conceive it as *Immaterial*, *Incorporeal*, *Invisible*, &c. because *Negative Attributes* do not so much declare *what a thing is*, as *what it is not*. Wherefore it will also much conduce to the attaining of *Knowledge*, if we always begin our Enquiries with those things that are more *Universal*, and from them to proceed to *Singulars*: Because the *knowledge* of *Universals* doth more accomplish our Minds, than that of *Singulars*; the reason whereof is, because *Universals* are in a manner *Eternal*, as having no Original, and not being comprehended within any difference of Time or Space of *Place*, which has given occasion to that noted Axiom of Philosophers, that *Science consists in Universals, and not in Singulars*.

VI. Things Positive are more distinctly conceiv'd, than Negative.

We shall the better understand all these Particulars that refer to clear and distinct Perception, by firmly retaining in our Memory, what hath been already handled in the First Part of *Logick*; hath been because this Fourth Part is founded upon those *Rules* which are there delivered, concerning the Genealogy of things, their *Causes* and *Effects*, *Subjects* and *Adjuncts*, *Agreement* and *Disagreement* of things, &c.

VII. We must call to Mind, what hath been said in the First Part of this Discourse.

The Second Precept about the Mode of *Knowing* is this, That our *Judgment* do always follow our *Conceptions*; that is, that we never assent to any thing which we have not before clearly and distinctly perceived: For the Order of *Reason* requires, that *Knowledge* always go before *Judgment*, and that Simple Terms make way for those that are Complex; but yet so, as that the *Judgment* we pass of any thing, may exactly answer to the *Knowledge* we have of it; as I have before hinted in the *Fourth Rule* for the attaining of *Truth*. For since the Second Operation of the Mind, or *Judgment*, doth involve two things, the *Subject*, and the *Predicate* or *Attribute*, it is necessary that the Nature of both be fully known to us, before we can judge whether the one do agree with the other, or differs from it. Thus we must first have distinctly understood what the *Sun*, and what *Heat* is, before we can affirm the *Sun* to be *hot*, or (which is the same) that *Heat* agrees to the *Sun*. As to which point they do greatly mistake, who too much cleaving to the *Prejudices* wherewith they have been tainted from their *Childhood*, do judge according to them; because they pervert the Order of *Reason*, and do not follow their Perceptions as they ought to do; but anticipate them, and believe them to be true; before they have perceived them to be such.

VIII. The Second Precept, about the manner of Knowing, is concerning Judgment.

If a Man chance to doubt of the *Truth* of the thing he is enquiring into, he may easily avoid falling into any Error, by suspending his *Judgment*, and not affirming or denying any thing concerning it, until he have exactly examin'd all the Difficulties of it, and by the Rules of *Perception*

IX. What is to be done by him who is in doubt about the Matter propounded have to him.

have removed all doubts concerning it. For we must not think it enough, that this or the other thing appears distinctly and clearly to others; except it appears likewise to us. For seeing every one desires Knowledge for himself, it is but reasonable, that he make use of his own Understanding, and not of anothers; and that he pass Judgment so far only, as his own Knowledge guides him. Wherefore, before we can with any safety give our assent to any thing, we must be certain that the thing be so indeed, as it is conceived by us, and not only so, but that it cannot be otherwise.

X. Yet are not we to conceive that all things that are true, are of the same certainty; for some things are only *Contingently* true, that is, such as are taken to be true by us, tho' indeed they may be false; as when I take a Man to be *Godly*, because he is frequent at Church, and at Sermons, and is liberal to the Poor; all which Signs are sufficient *Morally*, to persuade me that he is *Godly*; tho' notwithstanding all this, it may happen that he is not so. Other things again, are altogether *Certain* and *True*, as are all *Propositions* of *Eternal Truth*, which are true in that degree, that they cannot admit any suspicion of *Falshood*. Such as are these Propositions, *Twice four make Eight. Three is a number.* And therefore such necessary Propositions as these are called *Axioms*; because their Predicates agree with all their Subjects, and at all times, and according to the different degree of necessity, they partake and admit of several Names.

XI. Some *Attributes* are said to be joyned with their Subjects, by a *Physical* certainty, when according to the order of Nature, it is impossible but they must be joyned to them; as when we say, that a *Man hath two Feet*; because, that tho' a Man may be conceived without Feet, yet Naturally Man is never without them. Other things are called true, by *Metaphysical* certainty, when an *Attribute* is so indissolubly attributed to its Subject, that it cannot be conceived to be otherways: As when we say, *Three is a number.* And the same may be said of singular *Axioms*, forasmuch as the same *Definitions, Differences* and *Attributes* occur in them as in *Universals*. As to Judgment, the Reader may have recourse to what hath been said in the second part of *Logick*, where is treated of *Judgment*, and the nature of *Propositions*.

XII. And forasmuch as it is of little use to know the nature of things, except we remember them; we are also to be informed, how the things we understand, may be so *imprest* on our *Memories*, that we may not easily forget them again. This we may easily procure, by following the Order of our *Method*; that is, by taking care, that we commit nothing to Memory, which we have not before thoroughly examined, and passed a right Judgment of. For daily experience shews us, that the more clearly any thing is perceived by us, the stronger it is *imprest* on our *Memories*, and that we more easily remember the things, that are in order propounded to us, than those which are offered to us confusedly. For the *Memory* doth of it self, and spontaneously embrace things that are clearly understood, and, as a Foot-boy, follows right Judgment.

XIII. But yet we may promote and assist our *Memory*. First, By keeping our Mind still and quiet, without suffering our Understanding to be variously

distracted by multiplicity of Objects: Especially if to these we add the desire of Learning some new thing or other, or that we be excited by admiration to insist the longer on the matter we desire to know. For such things as these we are wont more to imprint in our *Memory*. It is also greatly strengthened by moderate Study and frequent Excitation. For as the *Fingers* by playing upon a *Lute*, do accustom themselves to such and such Motions, so by Exercise we attain to ability and readiness. To which we may add, that by Study, the Species in the *Brain* become distinctly ranged and joyned, and by use alone, almost all obstructions are removed. Thirdly, It will be a great help to our *Memory*, if the things we commit to it be not only evident, but also connexed, and orderly disposed, and adorned with the *Circumstances* of *Causes, Effects, Time, Place* and other such like. This is the first office of *Memory*.

It is the office of *Memory*, to retain the things we have committed to it; which we shall obtain by frequently repeating, and a diligent consideration of them: As likewise by endeavouring to reduce Compound Things to those that are *Simple*, and special things to *General*. For by this means, they will more clearly be represented to our *Minds*, and more firmly fixed in our *Memory*: As is apparent in those *Sciences*, which from simple terms proceed to *Propositions* and *Axioms*; which without any trouble, are insinuated into our *Minds*, and continue with us till our *Lives* end.

CHAP. XXI.

Concerning special Method; and first of that which is called *Analytical*.

THE word *Method*, is taken more strictly here than in the foregoing Chapter; because it being there, only our design to inform *Beginners*, what Order they were to observe in the knowledge of *Things*; it was sufficient to set down a *Method*, disposing which might be helpful to them for this end, and point out to them the way, whereby to arrive at the distinct knowledge of *Things*. But here we are to handle, not only how we ought to form our Conceptions, but also how we ought to order and dispose them, either for the discovering of the *Truth* we are ignorant of, or for the proving of the *Truth* we know to others.

And accordingly there is a twofold *Method*, the one called *Analytical*, or the *Method of Resolution*, which shews the true way, by which the thing was Methodically and Primarily invented. The other *Synthetical*, or the *Method of Composition*, which clearly demonstrates what hath been concluded; but by an opposit way, and set out *a Posteriori*. For a whole *Science* cannot be set down according to *Analytical Method*, but only some particular *Questions*, about certain *Terms* or *Things*.

About *Terms* we may enquire, what is to be understood by the *Word* in Question; for seeing that some *Words*, belong to *Notions*, that are common to all Men; and other proper or peculiar to some that profess some certain *Disciplines*: We are to mind, what Men are wont to understand by the *Word*; or what the *Masters* of those *Disciplines* are used to signify by them; or what he means by them, who makes use of them in *Writing* or in his *Speech*. For it cannot be doubted, but that the most

XIV.

Another
Method necessary to
the orderly
disposition
of our
Thoughts.

II.
Method is
twofold,
Analytical
and *Synthetical*.

III.
What is to
be observed
about Terms

most part of our disputes arise from the Ambiguity of Words; whilst one takes them in one Sense, another in another; which disputes might easily be decided, if the Parties in contest were agreed about the signification of the Word in question.

IV.
What is to be observed about things.

About the thing it self, we are to consider *what it is*, that is, what its Essence and Properties are. *Whether it be*, that is, whether it exist in the Nature of Things; and if it do, whether its existence be possible or necessary. *Whence it hath its Origin*, whether from it self, or from some other thing; and if it proceed from another, whether by Creation or Generation. Of what Nature it is, *Material* or *Intellectual*, and with what Faculties it is endowed, &c. Of *what quantity*, or bigness it is, and what space it takes up amongst other Bodies, if it be *Material*; and what if it be *Intellectual*, what its Powers are. *What effects it produceth*, that is, whether it be a Principal Cause, or an Instrumental only; whether it work voluntarily or necessarily; whether it be Univocal, or Equivocal, &c. *How it is distinguished from other things*, or what distinction there is between it, and other things, and whether it differ from them really, or Notionally only.

V.
What a Question is.

Analytical Method being the Art which guides Reason in the Research of Truth, we must before all things, endeavour to know the Nature of the Question, which we are to examin, and to consider afterwards, how many sorts of Questions there may be made. Questions are Propositions, which include something that is already known, and something that is unknown. For otherwise, they would be rather known Truths, than Truths to be known; and if they did not also contain something that is known, they could not properly be called Questions, because we cannot proceed to that which is unknown, but by means of something that is known.

VI.
There is a four-fold way of searching out the Truth of things: First when by the Effects we find out the Cause.

All Questions concerning things may be reduced to four Species. First, When from the Effects we find out the Cause. As for Example it is Notorious, that the Sun shining upon a Prism, represents therein variety of Colours; the Question is, what is the true cause of so many divers Effects. It is a known thing, that Air and Water are subject to Rarefaction, and that at one time they take up more space than at another: the Question is, what is the reason of this change, and what there is in Nature, that can encrease the quantity of Bodies.

VII.
The second is when from the Causes we enquire into the Nature of the Effects.

The second sort of Questions is, when Effects are endeavoured to be discovered by their Causes. It is a known thing, that Wind and Water have great force in them, to move Bodies; but our Fore-Fathers, for want of due attention, not considering duly what Effects might be produced from those Causes, did not make that good use of them, as we now do, by the useful inventions of Watermills and Windmills, and many other conveniences, by which abundance of human labour is spared, which is an advantage of true Natural Philosophy. The first sort of Questions, in which the Cause is searched out by the Effects, are the total Object of Natural Philosophy; and the second sort, in which the Effects are enquired into by the Cause, are the whole Practice of it.

VIII.
Thirdly, when from the Parts

The third sort of Questions is, when from the Parts we enquire into the Nature of the whole; as when after having set down several Numbers, by

adding them together, we enquire, what Number results from them all. Or when having got two Numbers, we enquire, what they produce by mutual Multiplication.

The Fourth is, when having a whole, and some part of it, we search out the other part of it: As, when having a determinate number, and that part which is to be taken from it, we enquire, what number will afterwards remain to us. By the Word Part in this place, we are not strictly to understand, only the Part of a thing, but whatsoever doth belong to any Substance, such as are Modes, Properties, Accidents, and in a Word, all the Attributes that are found in any thing.

That we may be able to answer these Questions, in the First place, it is requisite, that we clearly and distinctly conceive the point, that is precisely enquired after. Secondly, that we do not precipitate our Answer, till we have discovered whatsoever belongs to the Question, by certain Signs and Tokens, and not imitate those, who hearing their Friends Name, presently conceive it to signify that particular Person, and give their answer, before they know what he, who asked the Question, means by it. Thirdly, Forasmuch as in every Question, there is something concealed, we must be careful to denote that which is hid, by some certain Conditions, which may determine us to the seeking of one thing, rather than another, and which may induce us to judge, that that which we have found is the very same thing, that was enquired after. Fourthly, After we have examined the Conditions, let us set our selves seriously to consider, whatsoever in the matter propounded is either hid from us, or clear and evident to us; forasmuch as by means of this, we may arrive to that which is unknown to us. And in this our Attention to that which we know of a thing, in the resolving of a Question, Analytical Method chiefly consists. The whole Art and industry whereof consists in this, by this Examination, to find out several Truths, which may lead us to the knowledge of that thing, which we are endeavouring to discover.

Analytical Method therefore is nothing else, but a Particular application of the Mind, to that which is known, of that which is most particular in the Question to be resolved; whence it successively deduceth other Truths, which lead it at last, to the thing it desires to know. I say, that Analytical Method is a particular Application of the Mind, to that which is known; to observe that which Analytical Method, hath in common with Synthetical, which also begins with that which is known. And add, of that which is most particular in the Question it would resolve. To intimate the difference that is between the Analytical and Synthetical Method; and that this latter takes that which is known, of that which is most general in the Questions; whereas the other takes it of that which is most particular in them.

As suppose the Question to be whether the Mind of Man be immortal; and to find out this, we consider the Nature of the Mind, and presently discover, that Thinking is the property of the Mind of Man, which tho' it might be supposed to doubt of every thing besides, yet cannot doubt of its own Thinking, since its doubting is a kind of Thinking. Afterwards it proceeds to examin what it is to Think, and when it perceives that nothing is

included in its *Idea*, of what is involved in the *Idea* of an *Extended Substance*, or a *Body*: Yea, that it may be denied of *Cogitation*, that it belongs to the *Body*, forasmuch as it is something extended in *Length, Breadth, and Depth*, hath *Parts*, is of such and such a *Figure*, is *Divisible*, &c. without destroying the *Idea* we have of *Cogitation*: We conclude, that *Cogitation* cannot be the *Mode* of an *Extended Substance*; because the *Nature* of a *Mode* is such that it cannot be conceived, when the thing whose *Mode* it is, is denied of it. Whence it may also be infer'd, that seeing *Cogitation* is not a *Mode* of the *Body*, it must needs be the *Attribute* of another thing; and that therefore a *Thinking Substance*, and an *Extended Substance*, are two distinct *Substances*. From which finally we conclude, that the destruction of the one, doth not infer the destruction of the other. Add also, that *Extended Substance* cannot properly be said to be destroyed, since whatsoever we may call its destruction, is nothing else but a change or dissolution of some *parts* of the *Matter*, which still remains the same in *Nature* as it was. As when all the *Wheels* of a *Watch* are broken, we may easily judge that no part of the *Watch* is destroyed, tho' the *Watch* itself be commonly said to be spoiled or destroyed. From which *Example* it appears, that the *Soul*, which is not *divisible*, neither consists of any *parts*, cannot perish; and consequently that it is *Immortal*.

XIII. *Analytical Method proceeds from a heedful Consideration of a thing.* Whensoever therefore the *Nature* or *Cause* of any thing is proposed to our Examination, we must in the first place accurately examine all the Conditions of the *Question* propounded, without minding such as are *Extraneous*, and do not belong to the *Question*. Secondly, We are to separate those things which are certain and manifest from those that include any thing of *Confusion* or *Doubt*: For we are to search and trace out the thing we enquire for, from clear and evident *Idea's*. Thirdly, Every Difficulty we meet with is to be divided into *Parts*, which *Parts* are to be considered by themselves. For *Partition* is like a *Torch* to a *Learner*, directing him which way he is to go, without uncertainly wandering up and down. Fourthly, We are orderly to dispose of our *Perceptions*, and the *Judgments* we frame thence; so that beginning from the most easie, we may proceed by degrees to those that are more difficult. Wherefore our chief business must be, diligently to consider, and well to weigh those *Particulars* chiefly, which are clear and perspicuous in the *Question*, and not proceed to those that are unknown, except we find that by those which are already known to us, we are likely to Master them. Fifthly, That the *Thing* in question, be furnish'd with some *Note* or other that may determine it, and make us judge it to be the same, whenever we meet with it.

XIV. *An Example of the aforesaid Analytical Method.* As by *Example*, it is apparent that *Water*, and all *Liquid things*, have their *Parts* in *Motion*: For we see that *Water* dissolves *Salt* and *Sugar*, which would not be, if the insensible parts of the *Water* by their continual motion, did not run against the *Salt* and *Sugar*. And if we enquire into the Cause of this *Motion*, we shall find that *Water* and other *Liquid Bodies*, are not moved of themselves, because they are *Bodies*, since all *Bodies* are not moved, and those which rest are *Bodies* as well as those which are moved. Wherefore we are to

seek for a *Foreign Cause*, which produceth *Motion* in *Liquid Bodies*, and makes them to dissolve the *Particles* of *Salt*. And finding that the *Air*, by penetrating the *Pores* of the *Water*, cannot be the Cause of this *Motion*; for whence should the *Air* have the force to agitate all the parts of the *Water*? it remains that we assign some other *Matter* more subtil than *Air*, and more fluid, which may put the *Air*, *Water*, and other *Liquid Bodies* into *Motion*, which in the General Part of our *Natural Philosophy* we shall declare to be the *First Element*. For the more subtil any *Body* is, or divided into less *Parts*, so much the more easily it is agitated, and being once put into *Motion*, doth the more easily retain it. Wherefore the most subtil *Aether*, or *Celestial Matter*, must be supposed to be the first Principle of *Motion*, which *Matter* abounds in the *Fire*, *Sun*, *Fix'd Stars*, *Spirit of Wine*, and other *Liquors*.

Wherefore in the *Analytical*, as well as *Synthetic* Method, we are always to proceed from that which is more known, to that which is less known. This Rule is common to all Method, neither is any to be accounted true that deviates from this Principle. Yet there is this difference between the Method of *Resolution*, and that of *Composition*; that in the former, the *Known Truths* used in the Examination of the thing, which is propounded to be known, are taken from *Particulars*, and from them we do (as by special Steps) ascend to *Generals*; not as is done in the latter, where beginning with *Generals*, we come down to *Particulars*. So that these two Methods differ, as the *Ascent* or *Descent* of the same *Hill*; or the *Way* whereby we go up from the *Valley* to the *Top of the Hill*, and again come down from thence to the *Valley*.

CHAP. XXII.

Of the Method of Composition.

THIS Method is called the Method of COMPOSITION, because it makes use of *General* and *Compound* things, to come to things *Particular* and *Compound*: As for Example, If I have a mind to teach another by the way of *Synthetic* Method, that the *Soul* of *Man* is *Immortal*, I begin with these general *Maxims*; That Every Being is either a *Substance*, or a *Mode*; that there are two *Substances*, viz. a *Thinking Substance*, and an *Extended Substance*; that no *Substance* can properly be said to perish; that what we call Destruction in a *Bodily Substance*, is only a Dissolution of its *Parts*: Whence I conclude, that that which hath no *Parts*, as the *Soul*, cannot be destroyed, and that by consequence it is *Immortal*. I have said, that the Method of *Compounding* proceeds from more *Universal* things, to such as are less *Universal*; and it does so, because by this way of proceeding, all Repetitions, which commonly occasion *Confusion* and *Tediousness*, may be avoided. For should we treat of *Species*, before we have spoken of the *Genus*; forasmuch as we cannot know the *Species*, without knowing the *Genus* first, we should be fain to explain the *Nature* of the *Genus*, as often as we had occasion to treat of any *Species*. But because this way of Demonstration is peculiar to *Geometricians*, and is look'd upon by them as very necessary to persuade Truth, we will borrow from them whatsoever we have

have to say concerning it, to the end that we may follow the same way in searching out the Knowledge of other things, which they use in the demonstration of Matters Geometrical.

III. What things Mathematicians make use of in their Demonstrations.

Mathematicians are wont to deduce those things that are of the greatest moment and weight from known and easie Principles, by a Chain of Simple Truths; which they refer to three kinds; the first whereof includes Definitions; As, a Right Line is that which is the shortest betwixt two Points. A Point is that which hath no Parts. The second contains Postulata, or things demanded or taken for granted, which are so evident as to need no confirmation, and want nothing but the Hearers assent, viz. that from any Center, and at any distance, a Circle may be described. The Third comprehends Axioms, or common Notions of the Mind, which are not only manifest and evident in the Science we are treating of, but also in all others: As that all Right Angles are equal amongst themselves; that which is Equal, is bigger than all its Parts taken together.

IV. Three things are required to the Extorting an Assent.

Hence three things are chiefly observed by Geometricians, for the forcing of Assent. First, That no Ambiguity be left in the Terms, which is easily avoided by the Definitions of the Terms, which (as was said before) are nothing else but open Explications of the Terms and Words by which the things under debate are signified. The Second is, That every Ratiocination be founded on clear and distinct Principles, being so evident, that whosoever rightly understands the Words, must needs give his Assent to them. Which is the Reason why Mathematicians do always presuppose their Axioms, which they require to be granted them, as being so evident, that they stand in need of no Explication. The Third is, That every Conclusion they propound be proved demonstratively, making use only of those Definitions they have already alledged, or such Principles as have been granted them: Or lastly, Propositions, which by force of Argument they have deduced from them. So that all which Mathematicians observe concerning this matter, may be reduced to these Heads, which we shall comprehend in the following Rules.

Rules of Definitions.

V. First Rule of Definitions.

The First, That every Obscure or Equivocal Term be defined.

VI. Second Rule.

The Second, That no Terms do enter the Definition, which are not altogether clear, or have not been before explained.

Which two Rules are of that necessity, that they cannot sufficiently be imprinted in our Minds; forasmuch as by this means many Disputations are taken out of the way, which oft consists only in the Ambiguity of Words; as when the same Term is by divers Persons taken in a different Sense; which is a thing that happens very frequently in Schools. Wherefore, for the Removal of so many Disputations, which often do arise amongst the divers Sects of Philosophers, it will be sufficient, if the Disputing Parties take care to explain distinctly; and in few words, what they conceive by the Term about which they Dispute, and what they would have others to understand by it. As for the Qualifications of the Definitions of things, of these we have treated in the Fourteenth Chapter.

The Rule of Axioms.

This is a Rule of Axioms, That no Propositions be set up for Axioms, but such as are most manifest and evident. VII. A Rule for Axioms.

For no body questions, but that there are some Common Notions of the Mind that are so clear and perspicuous, as to stand in need of no Demonstration, to make them appear more distinctly. For did they involve the least Doubtfulness, they could not be the Foundation of a certain Conclusion. And therefore they are called Axioms, or common Enunciations, because they are so clear and manifest, as to stand in need of no Demonstration.

But we are not to suppose, as some do, that the Certainty and Evidence of Propositions doth in any degree proceed from the Senses; for that is absolutely false. For the Truth-discerning-Faculty is not placed in the Senses, which are often deceived by a Similitude of Things, and are not able to dive into the Difference that lies hid in them. Who is it that doth not experience how narrow and weak our Senses are, and how frequently they deceive us, when we go about to search out any thing by their means? VIII. The Evidence of Axioms doth not arise from the Senses.

For altho' this Axiom, That the Whole is greater than any one of its Parts, be in some sort discernible by the Senses, yet not with such a Certainty as is necessary to Science; because whatsoever our Senses discover to us concerning it, is only founded on the observations of our Infancy, which cannot afford us an undoubted, but only a probable Certainty. For by Induction a thing cannot be certainly known, except we be certain of the fulness of the Induction; there being nothing more common, than for us to discern at last the falsity of those things, which from general Inductions we were persuaded to be most True. The whole Truth of this Proposition, the Whole is bigger than its Parts, doth depend on the clear and distinct Notions we have of the Whole and Parts, by which we judge that the Whole is greater than any one of its Parts, and that the Part is less than the Whole. For when we are discoursing of any thing that is firm and stable, we must not have recourse to the Senses, as Plato saith; but to constant, immutable, and impregnable Reasons. Thus we clearly know, that a Triangle is a Figure, that the Number Two is an even Number; because the Notion of a Figure is contained in the Definition of a Triangle; and in that of the Number Two, the Notion of an Even Number.

Wherefore all the Certainty of our Knowledge in Natural things, depends on this Principle, Whatsoever is included in the clear and distinct Idea of any thing, the same may with truth be affirmed of it. Thus because Substance is included in the Conception of a Body, we may affirm a Body to be a Substance. Because it is involved in the Idea of a Circle, to have equal Diameters, we may assert of every Circle, That all their Diameters are Equal. Because it is included in the Idea of a Triangle, that all its Angles are Equal to two Right ones, we may affirm the same of all Triangles. What must be the Qualifications of Axioms, appears from what we have said of the framing of Propositions that are necessarily true, in the Thirteenth Chapter.

Most

Most General Axioms.

X. To have many Axioms in a readiness, is a great help to ready Arguing or Ratiocination.

But forasmuch as it is of great use, to have good store of *Axioms* at hand, whereby to prove and discover what is obscure and abstruse; it will be necessary to set down here some general and necessary *Propositions*, from which as so many *Fountains*, more special ones as *Rivulets* may be derived.

I. *Whatsoever is comprehended in the clear and distinct Conception of any thing, the same may with Truth be affirmed of it.*

For since in the clear and distinct *Conception* of a *Body Extension* is contained, and *Cogitation* in the *Idea* of the *Soul*, I can truly affirm of a *Body* that it is extended; and of the *Soul*, that it is a *Thinking Substance*. Wherefore we are to lay down this, as the *Foundation* of all *Sciences*; that we must never give our full assent to any *Proposition*, which doth not appear evidently true to us, so as that we cannot but assent to it, without doing violence to our *Minds*.

II. *In every Idea or Conception is involved either Possible or necessary Existence.*

Since nothing can be apprehended by us, except under the notion of being *Existent*; that is, necessary *Existence* is comprehended in the notion of a *Being* absolutely perfect, that is, of *God*; and possible *Existence* in that of a *Creature*, or of a limited and finite *Being*.

III. *Nothing has no Affections or Properties.*

So it cannot be said, that nothing is *Divisible*, that it hath *Parts*, that it can be moved, &c. Wherefore, wheresoever any *Property* is found, there we may assert that there is a *True and Real Being*.

IV. *Nothing cannot be the Cause of any Thing.*

Forasmuch as the *Cause* of a *Thing* is supposed to be, before it can produce any thing, and that Nothing cannot exist, it doth follow, that neither can it be *Principle* or *cause* of any thing. For if *Nothing* could ever be *Something*, it would follow, in opposition to the foregoing *Maxim*, that it must have some *Property*, which is a *Contradiction*.

From this *Axiom*, some others are deduced by way of *Corollaries*; such as are,

V. *Nothing, nor any Perfection of a thing, actually Existent, can have Nothing, or a thing not Existing, for the cause of its Existence.*

Another *Corollary*:

VI. *Whatsoever Reality, or Perfection there is in any thing, the same is formally, or eminently in the first, and adequate cause of that thing.*

Whence it follows, that the *Objective Reality* of our *Idea's*, requires a *Cause* in which the same *Reality*, is contained, not only *Objectively*, but *Formally*, or *Eminently*. For this *Axiom* doth not only belong to the *Efficient Cause*, but also to the *Exemplary*. For if an *Image* be made more excellent than its *Exemplar* or *Original*, so that more *Perfections* are found in it, than in the thing it self, after the likeness of which it is made, it cannot be said to imitate its *Exemplar*, and consequently cannot properly be called its *Image*.

VII. *A Thing or Substance, cannot naturally be Annihilated.*

That is, it cannot so cease to be, as that nothing at all should remain of it. For we easily conceive,

that when any thing ceaseth to appear, it doth change its *Nature*, or is converted into another thing; As for Example, we can well enough conceive, how *Wood* comes to cease to be *Wood*, how it comes to be *Fire*, and how the several *Particles* of *Fire* are subdivided into others, that at last they cannot be perceived by any *Sense*: But we can by no means conceive, how they should be reduced naturally to nothing, and from *Being* pass, to not *Being*.

VIII. *That which is clear and evident is not to be denied, because that which is obscure, cannot be comprehended.*

For we cannot doubt, but that there is *Liberty* and *Indifferency* in us, because we are conscious of it, and comprehend nothing more evidently or perfectly, tho' we cannot comprehend, how *God* doth leave the free actions of *Men* indetermined.

IX. *It is the nature of a Finite Mind, to be unable to comprehend that which is infinite.*

Because it is the nature of an *Infinite being*, to be *Incomprehensible*; for if it could be comprehended, it would not be *Infinite*. What wonder is it therefore, that we cannot conceive matter to be *Divisible* into *Infinite*? Or that we cannot understand the *Mystery* of the *Trinity*, or the *Incarnation* of the *Divine Word*? Because our *Mind* is *Finite*, and bears no proportion to the *Mysteries*. Would but some *Men* weigh this *Axiom*, as they ought, they would not with so much obstinacy, rely upon their weak *Reason*, or trusting to their own *Wits*, invent a new kind of *Divinity*.

X. *If you take Equals from Equals, what remains will be Equal.*

XI. *If you add Equals to Equals, the whole will be Equal.*

XII. *It is in vain to endeavour that by more, which can commodiously be performed by less.*

Special Logical Axioms.

To these we may subjoin some *Logical Axioms*, which are of great use, in the guiding of our *Discourse*, and are taken from the *Genus*, *Species*, of great use.

From the Genus.

I. *Whatsoever is affirmed or denied of the Genus, the same is affirmed or denied of the Species.*

The reason is, because the *Genus* contains the *Species*, and because the whole *Essence* of the *Genus* is found in them: Thus, because it is affirmed of an *Animal*, that it is *Sensitive*, the same is also affirmed of *Man* and *Beast*. And because the same *Animal* is denied to be a *Stone*, so likewise, the same is denied of a *Man* and a *Beast*. Wherefore, the *Genus* is of no use to prove the *Species*, but only to remove it. For that which is not an *Animal*, neither can it be a *Man*; but that which is a *Man*, must therefore be an *Animal*.

II. *The supposing of the Genus, doth not suppose such a Species.*

As for Example, supposing any thing to be an *Animal*, it cannot from thence be concluded, that it is a *Man*; because it may be a *Beast*, which is likewise an *Animal*.

III. *The Genus being destroyed, the Species must be destroyed with it.*

For seeing that the *Genus* is an essential part of the *Species*, it must follow that the *Genus* being destroyed, that must needs be destroyed with it, which consists of it. Thus if we take away an *Animal*,

Animal, we together take away the *Species*, that are contained under it. And by taking away a *Foursquare Figure*, we at the same time take away a *Parallelogram* and a *Trapezium*, which are the *Species* of a *Foursquare*.

From the Species.

I. The supposing of the *Species*, supposeth the *Genus*; but the taking away of one *Species*, doth not necessarily remove the *Genus*.

Because the *Idea* of the *Genus*, is comprehended in the *Essential Conception* of the *Species*, without which the nature of the *Species* cannot be explained. So supposing a *Binary* or the number two, we suppose a *number* also; and asserting a *Parallelogram*, we likewise assert a *Square*. And if all *Beasts* were taken out the *World*, yet would not *Animal* be therefore taken away, seeing it would be preserved in *Man*. Hence it is, that the *Species* is of great force to prove the *Genus*, but of none at all to deny it. For that which is a *Binary*, must be a *number*, but it does not follow, that that which is no *Binary*, is therefore no *number*.

II. All the *Species* being destroyed, the *Genus* is destroyed likewise.

For in this case all the power of the *Genus* is exhausted, neither doth there any thing remain, of which it can be affirmed. So supposing the *Sight*, *Hearing*, *Tasting*, *Smelling* and *Feeling* to be destroyed; the outward *Sense* must be destroyed likewise: And taking away *Prudence*, *Justice*, *Temperance* and *Fortitude*, takes away *Vertue* also.

From the Form or Difference.

I. The *Form* is that by which a thing is, what it is.

Because the *Form* or *Difference*, is the chief *Essential Attribute* that is found in the *Species*, and whose property it is to constitute the same, and distinguish it from other *Species*. Thus *Extension* constitutes a *Body*, and *Cogitation* the *Mind* or *Soul* of *Man*.

II. Where the total *Difference* or *Form* can be affirmed or denied, of the same the *Species* also may be affirmed or denied.

This *Axiom* as a *Corollary* is deduced from the former; for seeing the thing is constituted by the difference, where the same is found, it is necessary that there the *Species* be also. Thus, because *Cogitation* may be affirmed of the *Mind* of *Man*, therefore we may affirm it to be a *Thinking Being*.

III. The *Form* and *Species* are reciprocated.

The *Reason* is, because *Difference* constitutes the *Species*, and doth distinguish it from other *Species*, and therefore must have the same latitude as the *Species* it self, and therefore must reciprocally be affirmed of one another: As, *Every thing that Thinks is a Mind*, and *every thing that is a Mind Thinks*.

From the Property.

I. The *Property* is consequent on the *Form*.

For the *Property* is something flowing from the nature of the *Species*, and so bound to it, that it agrees to the whole *Species*: So *Divisibility* follows *Extension*, and is so necessarily joyned to it, that no *Body* can be extended, but that it must be *Divisible* also.

II. The supposing of the *Form*, supposeth the *Property*, and the taking away of it, takes away the *Property* also.

As when *Extension* is supposed, *Impenetrability* and *Divisibility* are supposed likewise; and if that be taken away; the *Properties* are taken away also.

From the Definition.

I. Whatsoever agrees with the *Definition*, agrees also with the thing *Defined*.

For seeing that a *Definition* declares the nature of a thing, by its *Essential Attributes*, viz. by its *Genus* and *Difference*, it must include the *Whole*, contained in the thing defined; and therefore whatsoever is *Attributed* to the *Definition*, the same must necessarily be also *Attributed* to the thing defined. Thus, because it agrees to the *Art of Discoursing well*, to direct the *Mind*; therefore also it must agree to *Logick*, to direct the *Mind*.

II. If the *Definition* belong to a thing, the thing defined must also belong to it.

Thus, because it belongs to the *Mind* of *Man*, to be a *Thinking Substance*, it belongs also to the same to be a *Spirit*. And because to a *Stone*, belongs *Extension* in *Length*, *Breadth* and *Depth*, therefore it also belongs to it, to be a *Body*.

III. If a *Definition* agree with a *Definition*, the thing *Defined* also, must agree with the thing *Defined*.

As, That which consists of a *Body* and *Mind*, is endowed with *Sense*; therefore *Man* is an *Animal*. *Substance* is something which hath an *Essence* and *Existence* distinguished from all other things; and on the contrary.

From Division.

I. If no part of the *Division* agrees to a thing, neither doth the thing divided agree with it.

Thus, because the notion neither of a *Spirit* nor *Body*, doth agree to *Substantial Forms* (save only the *Soul* of *Man*.) Therefore, *Substantial Forms* cannot be *Substances*.

II. Every *Division* must be entire, that is, it Enumerates all and every *Part* belonging to a thing.

For should any part belonging to a thing, be omitted in the *Division*, there could not be an Adequate Enumeration of the *Parts*, neither consequently would the thing, by means of such a *Division*, be distinctly perceived. Thus the *Division* of a *Man* into *Sound* and *Sick*, is not Adequate, because there is a kind of *Middle State*, as, is that of a *Man*, that is recovering from *Sickness*. But the *Division* of *Hand* into *Right* and *Left*; of a *Line* into *Right* and *Crooked*; of a *Number* into *Even* and *Odd*, is Adequate because it Enumerates all and every *Part*.

III. The *Parts* of a *Division* must be opposit.

This *Axiom* follows from the foregoing. Thus things are better divided into *Material* and *Immaterial*, than into *Visible* and *Invisible*; because some *Invisible things*, as a very clear *Air*, and our *Breath*, are not by nature distinct from *Visibles*.

From the Cause.

I. The *Cause* is always before the *Effect*.

For seeing the *Cause* is that from which a thing hath its *Original*, or that of which that *Being* doth in some sort depend, therefore it must needs exist before it. So a *Carpenter* is before the *Building*; A *Father* before the *Son*, &c. A *Cause* is in a twofold *Sense* said to be before its *Effect*, viz. by a *Priority* of *Nature* and *Time*. A *Cause* is before

its *Effect* by a Priority of *Nature*; because the *Effect* exists by the Power of the *Cause*, and not the *Cause* by the power and virtue of the *Effect*; yet not always by priority of *Time*, because some *Effects* exist at the same time with their *Causes*, as all those *Effects* which proceed by Emanation; as the *Proprieties* do from their *Subjects*, which therefore exist the same moment with them.

II. *Nothing can be a Cause of it self.*

For seeing there is a Dependance in the *Effect*, whereby it proceeds from something that was before it; it cannot be conceived, how any thing should be prior to it self.

III. *Supposing the Cause in Act, we suppose the Effect in Act also.*

The Reason is, because when the *Cause* is constituted in *Act*, it always does something, and that which it does is called its *Effect*. As supposing God a Producer, we must necessarily suppose something produced; and therefore the *Cause* and its *Effect*, as well as other *Relates*, are said to be *simul Natura*, that is, to be both at once; for no sooner is one *Relative* named, but at the same time we understand the other. So he is a *Father*, who hath a *Son*; and he a *Son*, who hath a *Father*.

IV. *A Cause cannot give that which it hath not.*

For a *Cause* gives something to another thing, but it cannot give that which it self wants.

V. *Whoever Acts by another, is esteemed to act of himself.*

As he who desires, exhorts, and adviseth others to commit some Wickedness, is said to be the *Moral Cause*; because by Desiring or Commanding, &c. He makes the *Effect* to be imputed to him.

From the *Effect*.

I. *The Effect is posterior to its Cause.*

This *Axiom* follows from the foregoing: For if the *Cause* be before the *Effect*, it follows that the *Effect* must presuppose it.

II. *No Effect exceeds the virtue of its Cause.*

For seeing the *Effect* borrows its Being from the *Cause*, it is impossible it should take any thing that goes beyond or exceeds the Power of its *Cause*. For *Fire* would never be able to warm the *Hand*, if to warm did exceed the virtue of *Fire*.

III. *That because of which every thing is such, is it self more such.*

That is, if the *Nature* of the *Effect* be good or bad; the same doth more clearly appear in the *Cause*. This is true when both are capable of the same *Quality*: Thus because the *Kettle* is hot because of the *Fire*, the *Fire* must needs be more hot. But we cannot argue, a *Man* is satiated with the *Meat* he eats, therefore the *Meat* is more satiated.

From the *Subjects*, and *Adjuncts*.

I. *Where the Subject is, there are the Adjuncts also.*

For seeing that the *Adjunct* is the Mode of the *Subject*, it does always accompany the same: As where the *Fire* is, there is heat; where a *Dead Carcase* is, there is a stink.

II. *Such as the Subject is, such are the Adjuncts.*

For such as the *Orator* is, such is his power in Persuading; as the *Sick* is, such are his symptoms.

III. *Where the Adjuncts are, there is the Subject.*

Because *Adjuncts* are added to the *Subject*, and are considered as things that belong to it. As where *Motion*, *Magnitude*, &c. is found, there must also be a *Body*.

From the *Whole*.

I. *What agrees to a Similar Whole, agrees also to the Parts of it.*

For seeing that a *Similar Whole* is made up of a Conjunction of *Similar Parts*, it must needs be of the same *Nature* with them. Thus, because *Lead* is heavier than *Brass*; therefore every part of *Lead*, proportion being observed, must be heavier than *Brass*.

II. *Where any Whole is, there are all its Principal Parts.*

For the *Principal Parts* are Essential to the *Whole*. I say, the *Principal Parts*, as the *Head*, and the like; because there are some *Parts* which belong to the *Entireness*, but not to the *Essence* of the thing.

III. *The Entire Whole being supposed, all its Parts are supposed also.*

The Reason is, because this *Whole* is nothing else than the *Parts* taken all together: As where the *Entire Body of Man* is, there must be its *Skin*, *Bones*, *Sinews*, *Veins*, *Flesh*, and all things that belong to the *Entireness* of it.

From the *Parts*.

I. *Every Part, with respect to its Whole, is Imperfect, and Incomplete.*

So the *Soul* and *Body*, with respect to a *Man*, are Imperfect and Incomplete; because they both belong to make a *Perfect Man*. So the *Hands*, *Feet*, *Head*, which are the *Integral Parts* of *Mans Body*, are more Imperfect than the *Whole Body*.

II. *Where all the Parts are, and joyned together, there is the Whole.*

This *Axiom* is evident from what hath been already said.

From *Like* and *Unlike*.

I. *Like do agree with Like.*

A *Prince* must govern a *Commonwealth* after the same manner, as a *Father* of a *Family* takes care of his *Family*.

II. *To Unlike things, Opposits do agree.*

As we love an *Honest man*, so we hate a *Wicked person*. A *Shepherd* feeds his *Sheep*, an *Hireling* neglects them.

From *Relates*.

I. *Relates are by Nature together, or at one and the same time.*

For seeing that every *Relation* is mutual, and one *Relative* respects the other; it cannot be, but that if you put the *Relate*, you must put the *Correlate* likewise: And therefore the *Cause* and the *Effect*, that which is before, and that which is after, and all other things that do mutually respect each other, are always at once and together in the *Mind*. From whence follows also this *Axiom*.

II. *One Relative being put, the other is put also; and being taken away, the other is so likewise.*

From

From Contraries.

I. *That which is susceptible of one Contrary, is also susceptible of the other.*

As *Water* can be made *hot*, therefore it may also be made *cold*. A *Dog* cannot act justly, and therefore neither unjustly.

II. *Of Contraries, it is necessary that the one be in the Subject susceptible of it; the other not.*

Thus if a *Number* be not *Even*, it must be *Uneven*. Yet this *Axiom* doth not hold in all *Contraries*; for it is not necessary that a *Wall* should be *white*, because it is not *black*.

From Privative Opposits.

I. *If the one be Absent, the other must be absent also.*

This must be understood in a *Capable Subject*. As if a *Man* sees, he is not *blind*. It is *Light*, therefore not *Dark*.

II. *For the Most part, there is no going back from a Privation to a Habit.*

As from *Death* to *Life*, from *Blindness* to *Sight*.

III. *What in one Subject is Privation, is often a Negation with regard to another.*

This appears in our *Errors*, which with reference to *God*, who doth not bestow upon us the whole knowledge of *Truth*, are only called *Negations*; but with reference to us are *Defects* and *Privations*. Thus *Ignorance* of the *Laws* is blame-worthy in him, who professeth skill in *Law*; but not to him who is of another Profession.

From Contradictories.

I. *One Contradictory being put, the other is removed; and on the contrary.*

As supposing that *Peter* walks, it cannot be that he should not walk.

From Parity, or Equality.

I. *Even things with Even things agree, or disagree.*

As *Faith* to the *Patriarchs* was necessary to *Salvation*; therefore to us also.

From the Greater.

I. *If that which is more Likely is not; much less that which is less Likely.*

As if a *Woman* could not be tempted to *Sin* by an hundred *Guineas*, much less by thirty.

From the Lesser.

I. *If that which is less Likely is, much more that which is more likely.*

As, a *Man* hath kill'd the *King*, therefore he will make no difficulty of killing one of his *Fellow-Citizens*.

From Divine Authority.

I. *The Testimony of a Being Sovereignly Intelligent, Wise, and True, is of greater efficacy to persuade, than any other the most strong and evident Reasons that may be.*

Thus since *God* tells us, that they are *blessed* who are persecuted for *Righteousness* sake, we are to hold it for an undoubted *Truth*; because we have a greater Certainty, that he who is *Sovereignly Intelligent*, and *Infinitely Good*, cannot be deceived, than we can be certain that we our-

selves are not deceived, even in those things that appear most clear and evident to us. For we are to give credit to the *Divine Testimony*, not because of the *Affirmation* or *Negation*, but for the Authority of the *Witness*, as being *Omnipotent*, *Omniscient*, and of the most *Sovereign Veracity* and *Truth*.

From Human Authority.

I. *We ought not to oppose that which is owned by all Men, or most Men, or wise Men, or by the most Famous and most Approved of them.*

As for Example, it is a *Truth* received by the common consent of all Men; that we ought to venture our *Lives* for the welfare and safety of our *Native Country*: And that it is the Duty of every *Man*, to live honestly, to hurt no body, and to give to every *Man* his *Right*. For this unanimous Agreement of all Men shews, that their *Judgment* in these Cases proceeds from common inborn *Notions*, and not from any Compact to impose upon others, or deceive themselves.

But yet we must not have the same Opinion of those Men, who being over-credulous, deceive others, by reporting *Prodigies* which they had from others; as that there are *Sciopodes*, Men that have but one Foot, and that so great, that lying on their Backs they can shade their whole *Body* with it; or that there are Men that have so great Ears, that they reach down to their *Feet*, and so broad that they can lye upon them; and others again that have no *Heads*, and have their *Eyes* about their *Shoulders*: Because we are not to believe every one, but only those whose sufficient knowledge of the Matters they relate, and *Veracity*, are fully known to us.

Two Rules of Demonstrations.

I. *All Propositions that involve any thing of Obscurity, are to be proved without alledging any thing in proof of them, besides Definitions which have gone before, or Axioms that have already been granted, or Propositions before demonstrated, or the Construction of the thing in discourse, when any Operation is to be done.*

II. *We are never to make an ill use of the Evocation of Terms.* This may be occasioned by not adding their *Definitions*, to restrain or explain them. For to every true *Demonstration* two things especially are required. First, That in the *Matter* it self nothing be contained, but what is certain and indubitable: The Other, That there be no fault in the Form of *Argumentation*: Which Faults we shall avoid by the Rules now given, that is, by not making an ill use of *Equivocal Terms*, and by using no other *Propositions* in our *Demonstrations*, but what are either *Definitions* of *Terms* before explained, or *Axioms* that have been before granted, and which ought not to have been supposed, without being sure of their Evidence; or *Propositions*, that have been before demonstrated; or the *Construction* of the *Thing* of which we treat, when any operation is to be performed. For by observing of these things all *Defects* or *Mistakes* will be easily avoided both in *Matter* and *Form*.

As to the Constitution of *Demonstrations*, we have handled it in the *Nineteenth Chapter* of the *Third Part*.

CHAP. XXIII.

Of Genetical Method.

I.
Themes are
two-fold,
Simple or
Conjunct.

HAVING largely enough, as I suppose, spoken of Method in general, and of Analytical and Synthetical in particular, it may now be fitting to subjoyn something concerning Genetical Method, because it is of use, and belongs to the true Practice, or Exercise of Logick. Genetical Method, teacheth us to frame a Discourse upon any Theme, and takes its Name from Genesis, because it is as it were a new Generation of a Thing, and that whereby we Elaborate a Theme, that hath not as yet been Explained, or Demonstrated. And for as much as the Theme, or Matter proposed to be known, is either One and Simple, or Conjunct and Complex; as when for Example, I consider God, or the Power of God, in Creating the World, I consider something that is Simple or Incomplex: But when I set before me this Sentence, God Created the World (or any other Proposition, whereby any thing is affirmed or denied of another) I think of something that is Conjunct or Complex.

II.
How we are
to handle
a Simple
Theme.

The handling of a Simple Theme, consists in the seeking of Arguments, that may declare a Simple Theme, and the disposing of them in a due order. Arguments shew us the manner of inventing the Definitions of Single Terms, such as are the Cause and Effect, Genus and Species, the whole and its Parts, Subject and Adjunct, Opposites, Divers, &c. As for Example, if any one seeks for the Efficient Cause of Man, he must have recourse to the Definition of the Efficient Cause, which is, that from which a thing by true Causality doth proceed: Which Definition of the Efficient Cause, if it be referred to Man, presently, either God will be brought to his Mind, by whom he was Created presently after the Beginning of the World; Or his Parents, by whom all other Men since have been produced. And after the same manner he may find out the Matter of which he is made, the Form by which he is distinguished from all other things; and the End for which he was Created by God.

III.
How the
Effects are
shewed.

So likewise the Effects of Man are manifested by examining the Works that proceed from Man, as the Efficient Cause, &c. and in like manner handle the rest, as far as the Theme propounded will bear: For it is evident, that all Themes will not admit the same Arguments; seeing God, for Example, hath neither any Efficient Cause, nor Form, nor Matter, and therefore the same cannot be considered of in him. The same may be said of the Angels, and the Mind of Man, which have neither Matter, nor Form, nor consist of any Parts.

IV.
In a Simple
Theme we
are to
examine the
Word.

In the handling of a Simple Theme, this order is commonly observed, as far as the nature of Argument will permit: First, To examine the Word of the Theme, whether it be derived, and if so, to give its Etymology: Secondly, Whether it be Ambiguous, and then its various Significations are to be Enumerated and expounded. Thirdly, Whether it be Abstract or Concrete.

V.
The Genus.

In the Second Place, we must enquire into the Genus, from the Predicamental Table set down in the First part, Chap. V. which represents all the Genera and Species, which conduceth much to the

knowledge of the Theme, forasmuch as the manner of handling Themes varieth according to the Diversity of the Genera.

Thirdly, We must enquire into the Causes, which we have set down and Enumerated, First part, Chap. IX.

Fourthly, The Effects are to be considered; not every one, but such as are Memorable, and worth the Mentioning.

Fifthly, The Adjuncts are to be handled according as the Theme is, whether Universal or Proper; as also the Antecedents and Consequents.

In the Sixth Place, Definition, which, as soon as we have found out the Genus and Difference, doth present it self unto us.

Next comes DIVISION, whereby the Subject is divided into its Integral Parts, if the Theme be an Integral Whole; or into Species, if it be a Genus.

In the Eighth Place, COMPARATES, or Things that agree in Quantity or Quality.

Lastly, OPPOSITES, are subjoyned to all these, and are of considerable use, according to that common Saying, Contraries set together, illustrate each other.

A Complex Theme, or Proposition is Genetically Demonstrated from the Subject and Predicat, which as two Integral Parts do constitute the same. Because by them we judge, whether a Proposition be True or False, Universal or Particular, Necessary or Contingent, Affirmative or Negative. As suppose this Conjunct Theme be to be proved, Man is Created after the Image of God, we are to consider both the Parts, viz. the Subject Man, and the Predicat, the Image of God, after which Man is said to be Created: Next the Quantity and Quality of the Proposition are to be Examined: And Lastly, The Reasons or Arguments of the Affirmation are to be investigated from the nature of the Subject and Predicat.

The Subject Man furnisheth us with Reasons or Arguments. First, From the Efficient Cause, because the Holy Trinity entered as it were into Consultation about the Creating of Man, which was not done in the other Works of the Creation, which is an Argument of a peculiar Prerogative of Man, before other Creatures, which consists in that he is an Image of God. Secondly, From his Matter, because he is made with a Face, directed towards Heaven, &c. Thirdly, From his Form, because he only of all sublunary Creatures, had a Mind breathed into him. Fourthly, From Singular Effects, which are the Evidences of a peculiar Virtue bestowed upon him. Fifthly, From his Adjuncts, because he excels all other Creatures, by the Power he has of Understanding, and determining himself. Sixthly, From his Definition, because he is a Substance consisting of Mind and Matter. Seventhly, From the Place of Comparats, because he comes near to the nature of the Angels; and Ninthly, From that of Opposits, because he is not a Beast, devoid of Reason.

The Predicat, made after the Image of God, doth also afford us Arguments taken from the Nature of the Divine Image; viz. from its Formal Reason, or from its Effects, Adjuncts, Parts, Definitions, Comparats, Contraries, &c. which Theology handles at large.

THE SECOND PART OF THE INSTITUTION OF PHILOSOPHY. Viz. Natural Theology, OR, A TREATISE CONCERNING GOD.

An Introductory Discourse Of the Definition of Natural Theology, and its Certainty.

I.
Why Natural
Theology is set
before the
other parts
of Philo-
sophy.

SOME it may be, will find it strange that I have given NATURAL THEOLOGY the precedence before other Parts of Philosophy, and that I betake myself to the demonstration of the Existence of GOD, and of his Perfections, before I have handled the Nature of Corporeal Things. But their Wonder will cease, if they consider how necessary Natural Theology is to other Disciplines, and of how great concern the knowledge of the Divine Existence is, for attaining a firm and evident Knowledge of all other Things. For seeing that GOD is the Author of the World, and all things that are in it, and the Original of all Truth, the Knowledge of him is to be premised, of whom all Certainty and Truth of Science doth so closely depend, as that without it no Evidence or true Knowledge at all can be had. For since Science cannot be had but from First Causes, how will the same be attainable by us, if we do not know them? Seeing it is the Nature of First Principles to be Clear and Evident; and that the Knowledge of other things do so depend upon them, that tho' Principles may be known, tho' the things be unknown; yet the things themselves can never be known, except the Principles be known: Seeing therefore that GOD, the Author of All Created Beings, is (according to St. Austin) the Light of all things knowable, and the Good of all

things to be done; we must know him, before other Causalities can either have a Being, or be exactly known by us.

Notwithstanding, that Geometrical Demonstrations be of that Evidence, as to force our Assent, and being once clearly perceived, do no longer leave any place for doubting, as long as we attend to them; yet will they cease to appear such, if we be ignorant of the Existence of God. For how can we know, but that we are made with such Natures as to be deceived in those things that appear most evident to us? For we cannot be convinc'd to the contrary, except we first know God to Exist, and that He is the Fountain of all Truth, and hath not given us such Understandings, as to be deceived in the Judgments we make of things that we do most clearly and distinctly comprehend.

True it is, that our Mind is conscious to several Ideas in itself, in the Contemplation whereof it never finds it self deceived, as long as it neither affirms nor denies ought concerning them. It is certain also, that it finds in it self Common Notions, whence it frames several Demonstrations, which it persuades it self to be very true, as long as it gives heed to the Premises from whence it deduceth its Demonstrations. But because it cannot continually give its attention to them, and often forgets them, it may afterwards easily come to doubt

II.
All Geometrical Demonstrations derive their Evidence from the Existence of GOD.

III.
We cannot be certain that any Proposition is true, but only as long as we do give heed to the Premises.

of their certainty, if it have not a clear and distinct Conception of God, that is, except it be assured that God is True, and that it is repugnant to his Nature to be a Deceiver. For as *Cartesius* saith in his Fifth Meditation, *Tho' I am of that Nature, that as long as I clearly and distinctly perceive any thing, I cannot but believe it true; yet because I am also of that Nature, as not to be able always to fix the intention of my Mind, upon one and the same thing, in order to my clear perceiving of the same, and that I oft call to Mind a Judgment I have made before, when I no longer attend to the Reasons, upon which I judged it to be such, other Reasons may be alledged, which might remove me from my Opinion, if I were Ignorant of the Existence of God; and consequently should never have any true or certain Science concerning things, but only Fleeting and Mutable Opinions.*

IV.
This confirmed by an Example.

Thus he who considers the Nature of a Triangle, is indeed forced to conclude, that its Three Angles are equal to Two right ones, neither can he think otherwise as long as he attends to its Demonstration: But yet as soon as he turns the bent of his Mind from it, tho' he remembers that he hath clearly perceived it, yet he may easily question the truth of it, if the Existence of God be unknown to him.

V.
An Objection taken from Atheists.

If it be said that *Atheists*, who deny the Existence of God, do notwithstanding clearly understand general Axioms, such as these, *Equal Quantities added to Equal, make the whole Equal: Those things which agree in a Third, do agree amongst themselves;* and such like: From which they easily Demonstrate, that the Three Angles of a right Angle, are Equal to Two right ones. And that it is a thing apparent to all that are skilled in the Principles of Geometry, that the Square of the Basis of a Triangle, is equal to the Square of the Sides: So that it is possible to have true knowledge, without supposing the knowledge of God.

VI.
Answered.

I Answer, That it cannot be denied, but that *Atheists* have a clear knowledge of Geometrical Demonstrations, and that they are so evident, as to force their assent: But yet this knowledge of theirs cannot be said to be true Science, founded upon certain Principles: Because no knowledge deserves the name of Science, that can in the least be called in doubt, and whose certainty doth not depend on an evident Principle. Now forasmuch as these Men are supposed to be *Atheists*, neither can they be certain that they are not mistaken in those very things, which they think themselves to have most clearly apprehended. And tho' it may be this doubtfulness do not trouble them at present, yet it may hereafter, upon their examining of the matter, or upon its being started by others; neither can they ever be secured from this Hesitation, without owning God to be the Author of their Being.

VII.
Natural Theology influences all human Disciplines.

NATURAL THEOLOGY transcends all the Parts of Philosophy; and as the Sun, that Enlightens all the World, is diffused through all Arts, and Sciences: For who is there, that considering the Works of God as he ought, doth not admire his Power, Goodness and Wisdom, and is not raised thence to the Knowledge of Him? Do not the Earth, the Water, Vegetables, Animals and Stars, all lead us to the Understanding of Him? For all things have relation to God, as to their First Principle, and proclaim him to be the one

Supream cause of their Being. For how is it possible for him, who attentively considers the Connexion of Bodies, the Motion of the Stars, the Vicissitude of Seasons, the Succession of Generations, the orderly Disposition of the Parts of the World, not to discern the Wise Author and Orderer of all these?

Bodies have no power to move themselves; how can therefore their so orderly Motion be performed, but by some Intellectual Being, by which as their Effective Principle, they are disposed, and directed to their appointed end? Wherefore *Lactantius* was of Opinion, that no Man could be so Ignorant or Savage, but that, lifting up his Eyes to Heaven, tho' he may not know by whose Providence all these things are govern'd, yet must needs understand from the Motion, Disposition, Constancy, Usefulness, and Contemperation of things, that they are under a wise conduct; and that it is impossible, that what is so wonderfully framed and ordered, must be managed, by the highest Counsel and Wisdom.

From what hath been said it appears what Natural Theology is, viz. the Knowledge or Science of God. For Theology is divided into Natural and Supernatural; Supernatural is called that which is fetched from Holy Scripture, and which, by the assistance of Supernatural Light, attains Divine Truths: Natural, is that, which declares and demonstrates the Existence and Attributes of God, from the Book of Nature, and from Principles, derived from the Light of Nature.

Wherefore, this Natural Theology is very profitable for Unbelievers, and Wicked Persons, that are Theoretically so, who cannot be brought to any Religion, except it be first demonstrated to them, that God Exists. As also for those who are Practical Atheists, that is, who live, as if there were no God; no Providence; no Reward after this Life, nor any Punishment; for how will these be able to defend this their Opinion, after that they are once convinced, that there is a God, and that his Attributes, are not only shadowed out in all things throughout the whole World, but besides are most clearly represented in their own Souls?

The Certainty of Natural Theology doth plainly appear, in that it is required to the laying of the Foundations of Human Disciplines, and in that without the knowledge of God, no solid Knowledge can be had of any thing whatsoever. He cannot be called a Philosopher, who is destitute of the knowledge of God, and who doth not worship him as he ought. Hence *Des Cartes* 1. Princ. Artic. 29. proves the certainty of the Natural Light given to him by God, by this Argument, because God is True, and that he is the Original and Principle of our Intellect.

CHAPTER I.

What God is, and how he may be reached by us.

Forasmuch, as according to the Rules of Logic, we are never to enquire, whether a thing be, before we conceive what it is: I suppose it needful to examine, what the Nature of God is, and what is included in the Essential Conception of him; before that I proceed to the Discussing of the Point, how his Existence comes to be known to us.

The

II.
All Men
agree in
the know-
ledge of
God.

The first of these will not be difficult, if we only follow the *Judgments of Men*, that ever had any Opinion of *God*: For I believe, that Men do less disagree in this, than in any other Opinion whatsoever. There is no Man that ever heard any thing of *God*, but doth acknowledge him to be a *Substance Infinite, Independent*, of the *Highest Understanding and Power*, and the *Creator of all things* that are. Or if he doth not distinctly conceive thus much, yet at least must own, that all Perfections that can possibly be conceived by Man, do belong to him in the highest and most perfect manner that can be.

III.
Tho' God be
infinite, yet
doth he not
therefore
exclude all
Finite Be-
ings.

It may be some will here Object, that if *God* be an *Infinite Being*, or such a one as comprehends all manner of *Perfections* whatsoever, he must necessarily exclude every *Finite Being*, and so nothing would exist besides him. But the Fallacy of this Reasoning is apparent; for we cannot conclude, that, because a Man hath a more excellent Wit than others, that therefore others have no Wit at all. Or supposing his Wit to encrease to *Infinity*, would this diminish the less Portion of Wit posselt by others? Thus, tho' *God* be consummate in all manner of Perfections, yet doth not he therefore exclude all other *Beings*; except we should conceive *God* to be *Corporeal and Material*; for indeed if he were *Corporeally Infinite*, he must exclude all other *Bodies*. But if we should conceive *God* to be *Corporeal*, we cannot suppose him *Infinite*, that is, comprehending all manner of *Perfections*, because then he would be *Divisible*, and lose his highest Simplicity and Unity.

IV.
Gods Per-
fections are
only Infi-
nite.

But some will urge further, that it is of the Nature of a most perfect *Being*, to include all manner of *Perfections*, and therefore it is necessary for him, formally to comprehend whatsoever *Perfection* is in the *Creatures*. To which I Answer, That the *Antecedent* is false, for seeing that the *Perfections* of the *Creature* are *Finite* and imperfect, they cannot be in *God*, because otherwise *God* could not be the most *Perfect Being*, as containing imperfections in himself. Wherefore we ought rather to say, since *God* is the *Highest Being*, he includes only *Infinite Perfection*, and excludes all other.

V.
How God
is said to
be Infinite.

God is said to be *Infinite*, because he is without all *Bounds*, not only as to his *Essence*, but also as to his *Duration*, as being a necessary *Being*, and Subject to no Change or Mutability.

VI.
God is In-
dependent.

He is said to be *Independent*, because he derives his *Being*, from none besides himself. Which yet is not so to be understood, as if *God* did depend of himself, as of an *Efficient Cause*, since it might be still further enquired, whether that Cause had its *Being from it self* or *from another*. But that he is posselt of so great and immense a *Power*, that he doth not stand in need of the help of any *Being*, for his *Existence* and *Conservation*; and that therefore in some *Sense*, *God* may be said to be the *Cause* of himself.

VII.
In what
Sense God
is said to
be Positive-
ly of him-
self.

You will say, that *Divines* will not allow this way of *Speaking*, as abhorring to admit the notion of *Causality* in *God*; and therefore when they would explain How *God* is from himself, they say, that that ought only to be understood *Negatively*, that is, *God* is not of another, but by no means positively of himself, as of a *Cause*.

I Answer, That it is true, that *God* is of himself

Negatively, or which is the same thing, that he is not beholden to any *Cause* for his *Existence*; but withal do assert, that this *Negation* is not sufficient to explain the Nature of *God*, without admitting something that is positive, by which he continues to be or exist; and this we say is nothing else but his *Inexhaustible and Incomprehensible Power*; for it is certain that the *Power, Efficacy and Vertue* which we conceive in *God*, is the most Positive, Perfect and Real that can be: And therefore, forasmuch as *God* exists by reason of his *Nature*, or the *Perfections* that are in him, who can question but that he is positively of himself? For if the first Man had been from *Eternity*, so as nothing had been before him, yet forasmuch as the *Parts of Time* in which he *Exists*, may be separated from each other; and because from his *Being* to Day, it doth not follow that he shall be to Morrow, except there be some cause to renew him, and as it were, to produce him anew every *Moment*; we make no difficulty to assert that the *Cause* which thus preserves is something *Positive*. Thus notwithstanding *God* hath been from *Eternity*, yet because he himself preserves himself, we may conclude he is of himself, not only *Negatively*, but *Positively*, inasmuch as his *Immensity* is the Cause of the Perseverance of his *Being*.

But you will say, if *God* be positively of himself, he will be his own *Cause*, or the *Cause* of himself, since he does the same with reference to himself, what the *Efficient Cause* doth with respect to its *Effect*. Now to say, that *God* is the *Cause* of himself, sounds harshly in the *Ears* of some *Divines*, and is looked upon as an Error.

I Answer, that *God* may be said, in some manner to be the *Cause* of himself, inasmuch as he is positively preserved by himself, as long as by the word *Cause* we do not understand the *Efficient*, but only the *Formal Cause*; so that the meaning of that Expression will be no more than this, that the *Immensity* of the *Divine Essence*, is the Reason why he doth not stand in need of any *Cause* for his *Existence* or *Conservation*; or that the *Divine Perfection* is so great, that he is the Reason of his own *Existence*, not diverse, but inseparable from himself. Which is not so to be understood, as if *God* by a *Positive Influx* did conserve himself, as all *Created Beings* are conserved by him; but only that this Supreme *Power*, and the *Immensity* of his *Essence* is such, that he stands in need of no *Conservator*. But now who will pretend, that this *Immensity* of the *Divine Power* is not a most positive thing? When therefore it is demanded why *God* *Exists*, we must not answer, by an *Efficient Cause*; because that is properly called an *Efficient Cause*, where the Cause is distinguished from the *Effect*, and where the *Effect* is supposed different from the *Cause*; but we are to Answer, by the *Essence* of the Thing or the *Formal Cause*, which bears some *Analogy* with the *Efficient*.

God is also acknowledged to be a *Being* of *Sovereign Wisdom and Understanding*, because nothing is hid from him, and because all *past, present and future things* are *Naked*, and open before him. Moreover *God* is acknowledged to be most *Powerful*, because he Rules over all, and can produce whatsoever doth not imply a *Contradiction*.

XV.
We may
have an
Idea of
God, with-
out com-
prehending
of him.

XVI.
The word
Cogita-
tion is
Equivocal.

He is also owned to be the Creator of all things, because all things depend on Him, not only to their Being, but also with regard to their Conservation. For since Infinite Power is included in the Idea we have of God, it is a Contradiction, that any thing should Exist, which is not produced by him.

Under these Attributes it is, that God may be known by us: For we have a clear and distinct knowledge of God as he is. A Being Infinite, Omnipotent, Eternal, Omniscient, and the effective Principle of all things. And he may be thus defined by us: A Being thinking in Perfection (or most perfectly thinking) Simple, Unchangeable, Eternal, Consummate, Necessary, Immense, Incomprehensible, Omnipotent, and of which all things depend, not only with regard to their Nature and Existence, but also to their Order and Possibility. Neither is it any Contradiction to what hath been said of our knowing him, that he is declared to be Incomprehensible: For it is one thing to know a thing, and another to comprehend it: I own that we who are Finite cannot comprehend the Infinite Essence of God, since it is of the Nature of Infinity to be Incomprehensible: But it is no Contradiction to say, we may know that which is Infinite, that is, clearly and distinctly apprehend a thing to be such, that no bounds or limits can be found in it, or set to it.

You will oppose, That if the Weakness of Man cannot aspire to the comprehension of that which is Infinite, he will never be able to conceive the Notion of that which is so, but only of that which is Finite: For who will say that he sees a Man, when he sees only one Hair of his Head? Now there is less proportion between a Finite thing and an Infinite, than there is between one Hair of a Man's Head, and his whole Body.

I Answer, That it is not at all needful, in order to our having the Notion of an Infinite thing, that we should comprehend all its Perfections, this being sufficient if we find no bounds or limits in it; because then we understand the whole Infinite, tho' not Totally, as the Schools term it, and as to every one of its Parts. Who dare say that I have not the Idea of a Triangle, when a Figure comprehended within three Lines is represented to my Mind; tho' it may be I am ignorant, that its three Angles be equal to two right ones? And so in like manner I may have an Apprehension or Notion of God, without comprehending all his Attributes. For if it were otherwise, I should understand nothing at all, when mention is made of the Worship of God, his Works, Mercy, or Justice. For it is not of the Essence of an Image, that it be in all things the same with the thing it represents, but only that it be in some degree like it.

But yet we are to observe, that the word a Thinking-Being, or Substance, is Equivocal when attributed to God and the Creatures; because the Cogitation, which constitutes the Nature of God, is Independent and Perfect, and that which constitutes the Nature of a Created Spirit is Imperfect, and dependent of God: Wherefore to mark this difference, I say, that the Cogitation, which constitutes the Nature of God, subsists by it self; whereas that which constitutes the Nature of a Created Spirit, subsists indeed in it self, but not by it self.

By the Inborn Idea that is in us, we know that GOD exists.

BY the word I D E A, we understand that form of our Cogitation, by the immediate apprehension whereof we are conscious of the said Cogitation: So that we can express nothing, without having formed an Idea before of it in our Minds. Or to express it shorter, An Idea is nothing else but the thing it self perceived or thought of, as it is Objectively in the Understanding. Wherefore every Idea includes two things, the one Formal or Proper, inasmuch as it is an Operation of the Mind; the other Objective, as it is the Image of a Thing thought, or is instead of it.

In the Second place we are to take notice, That tho' there is no inequality in the Ideas of our Mind, as they are Modes of Thinking; yet are they very different with respect to the things which they represent. For it cannot be question'd but the Idea, which represents Substance to me, contains more Objective Reality, than that which represents a Mode, or any thing else adventitious to a perfect or compleat Substance. And so that Idea which represents to me an Infinite Being, All-powerful, All-wise, Eternal, &c. doth undoubtedly contain more Objective Reality, than that which expresseth Substances that are Created, Dependent, Mortal, &c. For seeing that these Ideas are something, they must have a Cause of their Existence, and consequently have so much the more Reality, as the things they represent have of Entity.

Thirdly, we are to observe, That there is nothing found in any Effect, which is not Formally or Eminently contain'd in its Cause. A thing is said to be Formally in its Cause, when it is such there as we perceive; but Eminently, when the Cause can supply its stead. Thus Fire, when it produceth heat in a Body, is said to contain it formally, because it hath the very same thing in it self, which it hath produc'd in the Body; but the Sun and the Earth, when they produce Fruits, do not comprehend the thing caused by them Formally, but Eminently only. This Notion is the First of all others, and is as evident, as that Nothing can be made out of Nothing: For should we admit that something is contained in the Effect, which is not contained in the Cause, we must own that Something may proceed from Nothing. Neither can we give any other Reason, why Nothing cannot be the Cause of any thing, but because in it there cannot be found what is in the Effect.

Wherefore we conclude from the Idea we have of God, that he exists; which is, First, thus demonstrated: Every thing represented by an Idea must have a Cause, in which it is either Formally or Eminently contained; but we have an Idea of God, as he is a Most perfect Substance, excluding all Limitations: Therefore this Idea must have GOD for its Cause. The Minor is thus proved: There is nothing found in all Created Beings that can afford us this Idea: For tho' I can form the Idea of a Substance, because I my self am a Substance; yet will this Idea never represent an Infinite Substance, because I my self am Finite and of bounded Perfections; wherefore it is necessary that if I have an Idea of an Infinite Substance, it must proceed from God alone, who is Infinite.

V.
An Obje-
ction an-
swer'd.

If you argue, that this *Idea* may be formed from the several Perfections scattered up and down in the several Parts of the *Universe*; after the same manner as from the Notion of an *Angel*, and my own *Mind*, I can frame an *Idea* of a *Divine Understanding*. I answer, How can I from the several Endowments of diverse Things, frame a *Being* that is absolutely Perfect? Shall I do it by enlarging and extending those *Images*? But whence have I the Faculty of enlarging all the Perfections of *Created Things*, and concerning something that far exceeds them all? We ought rather to conclude, that this is, because the *Idea* of a most Perfect *Being* is impress'd upon my *Mind*. Moreover, the supream Perfection of *God* consists in this, That all his Perfections are not separate, as in the *Creatures*, but in conjunction with the most absolute *Simplicity* and *Unity*.

VI.
No Idea of
an Infinite
Being is
contained
in the Idea
of a Finite
Being.

And tho' the *Idea* of an *Infinite Substance*, which most perfectly includes all the Perfections our *Mind* can conceive, may also contain the *Idea* of a *Finite Substance*, (as a *Multitude* contains an *Unity*, and a greater Number a lesser;) yet is not the *Idea* of an *Infinite Being*, contain'd in that of a *Finite Being*. And therefore *Des Cartes* in his *Third Meditation* says thus: I manifestly understand, that there is more Reality in an *Infinite Substance*, than in a *Finite*; and therefore that the Perception of an *Infinite Being*, is in some sort precedent in me, to that of a *Finite Being*, that is, the *Idea* of *GOD*, to that of my *Self*. For how could I understand that I Doubt, that I Desire, that is, that I want something, and am not altogether Perfect, if there were not in me the *Idea* of a more Perfect *Being*, by comparing my *Self* with whom I discern my own Defects?

VII.
That which
is Perfect
cannot pro-
ceed from
that which
is Imper-
fect.

Secondly, That which is perfect cannot proceed from that which is imperfect, as from its *Total* and *Efficient Cause*: But we, as all other *Creatures*, are Imperfect; and the Perfections which are in *God*, are neither *Formally* nor *Eminently* contained in us: So that the *Idea* of *GOD*, which contains all his Perfections, cannot be thought to proceed from us, and consequently *God* must be the Cause of it; and because He cannot be the Cause of it, except He do exist, we may undoubtedly conclude that He doth so.

VIII.
The Idea of
God is in-
born in us.

If any one ask, whence we have this *Idea*, since it doth not proceed from our *Senses*, nor from any *Created Being*? My Answer is, That it is born with us, as the *Idea* of our *Selves* also is: For *God* impress'd it upon every *Man* in his *Creation*; and hath so order'd it, that every one should understand and know *God* by the same Faculty whereby He knows himself. For it is impossible that any one should understand himself to be imperfect, depending on another, and of uncertain Duration; but that at the same time he must also understand Him, with whom compared, he is imperfect; and on whom he depends; so that reflecting upon himself, he concludes that *God* is, and by the *Idea* which he hath of him, is convinc'd of his *Existence*. I say, by reflecting on himself; for by the impression made upon us by *God*, we are not to understand that this *Idea* is always actually represented to us; for were it so, we should always think of *God*: But by this *Impression* is meant nothing else, but that *God* hath vouchsafed

such a Faculty to *Man*, whereby he can excite this *Idea* in himself, without the help of any other *Idea's* whatsoever.

It cannot be said, That this *Idea* is framed or invented by us, as many *Notions* are, which have no other *Existence*, but what they have in our *Understanding*; because nothing can be added or taken away from this *Idea*, for the *Essences* of things are indivisible: So that if any Thing could be added to any *Idea*, representing the Nature of a Thing, it would be no more the same, but another *Idea*. And tho' new Perfections may still be perceived in *God*, which were not known before; yet doth not this change the *Idea* of *God*, but only makes it the more clear and distinct; no more than the *Idea* of *Man* is increased, when some new Properties are discover'd in him, which before were unknown, because they ought to have been included in the *Idea* which we had of him before.

But you will farther urge, That *Man* who has this *Idea* is a free Agent, and that consequently he can frame the same at pleasure. And *Des Cartes* seems to hint as much in the Beginning of his *Fifth Meditation*, where after he hath said, That innumerable *Idea's* of Things are found in his *Mind*, adds, Which tho' they be in some sort thought by me at pleasure. Now if we can think of Objects according to our pleasure, why may we not say, that the *Idea* of *God* is framed by us, whilst we are thinking of it?

I Answer, That *Idea's* do indeed depend on us, as far as they have a formal and proper Being in our *Mind*; but not as they are considered in their objective Being; because in that respect they have a necessary Cause: I own it to be in our power, to think, or not to think of any particular Object, and that we are thus free by a liberty of Contradiction, or by a liberty as to the Exercise of the Act, as the *Schools* express it; but that it is not in our power, to think differently of the same thing that is true, that is, we have no liberty of Contrariety, and as to the Specification of the Act. For it doth not depend on our Will to think the Number Nine to consist of three Ternaries, and not to consist, or to be an Even or Uneven Number, &c. Neither can we conceive a Substance absolutely perfect, as Existing or not Existing, Wise or Ignorant, Merciful or Cruel; but must necessarily conceive him necessarily Existing, All-wise, and All-good. Wherefore when *Des Cartes* saith, That many *Idea's* are found in him, which it may be have no Existence, besides his Cogitation, he presently subjoins, yet are they not feigned or invented by me, but have their true and unchangeable Natures.

Neither doth it contradict our Assertion, what some say, That we have deriv'd all the Knowledge we have from our Parents; who having receiv'd the same from the first Men, afterwards communicated the same to us, and that consequently the *Idea* we have of *GOD* is not in-born, seeing that this Objection seems rather to confirm the *Idea* of *GOD* to be in-born in us: For let us ask them, from whom those first Men had this *Idea*; if from themselves, why may not we have it as well? If from *GOD* revealing the same to them, then they must own *GOD* to Exist.

Q. CHAP.

C H A P. III.

That it belongs to the Nature of God to Exist.

I. *Whether Existence doth appertain to God.*
 I Have evidently enough, as I suppose, Demonstrated in the foregoing Chapter, that because I find in my self the Idea of a Being absolutely Perfect, therefore that Being must Exist. Now I proceed to shew whether the Existence of God, can be proved from the consideration of his Nature, and whether a Possible only, or a Necessary Existence do belong to him.

II. *The Existence of any thing may be enquired into after a two-fold manner.*
 Two Questions may be formed of a thing that Exists in Nature, the one with respect to our Knowledge, the other with respect to the Thing considered in it self. By the First, the Reason is sought, why any thing, suppose God or the Soul, is affirmed by us to Exist: By the Second we enquire, how it comes to pass, that the said thing is not only Possible, but really Existent. By either of these ways we may enquire after the Existence of God, for we have Reasons that not only assure us that God Exists, but also that this his Existence is necessary.

III. *The Idea of an Infinite Being prove its Existence.*
 Neither will it be hard to Demonstrate this, if we attend to the Idea we have of God, viz. that he is Infinite, all Powerful and all Perfect: For we argue thus: Whatsoever we clearly and distinctly perceive to belong to the Essence of any Thing, the same we know to be true as we perceive it; but we clearly and distinctly understand, that it belongs to the Essence of God that he Exists; therefore it is true that God Exists. The Minor is thus proved; It is a contradiction for a most perfect Being, to want any Perfection; but Existence is a Perfection; therefore God cannot be conceived, but Existent. For since where a Multitude is, there must needs also be a Unity; therefore since God possesseth all Perfections conceivable, he must of necessity also have Existence.

IV. *The Existence of God is necessary.*
 Neither doth it oppose the Truth of what hath been said, that in all other Created Beings, the Essence is distinguished from their Existence; and that it doth not follow, that a thing doth exist because we have a Notion of it. For the Reason thereof is, because in the Idea of all other Things only Possible, and not actual Existence is contained, whereas the Nature of God includes actual, necessary and Eternal Existence: So that it is as impossible for us to conceive a Hill without a Valley, as to conceive an absolutely perfect Being, to whom any Perfection is wanting, or who is not Existent: For as Cogitation presupposeth the Existence of a thing Thinking, for if it had no Being, it could not Think: So absolute Perfection presupposeth necessary Existence, since nothing can be conceived absolutely perfect, except it Exist.

V. *Existence is a Perfection without which the nature of God cannot be conceived.*
 Wherefore in this point, we differ from Gassendus, who denies Existence to be a Perfection, or the Propriety of any thing, but that which adds neither Perfection nor Imperfection to a thing. Because when we attend to the Notion of God, we perceive, that Existence is a Divine Property, and no less belongs to God than Omnipotence or Immensity, &c. or that an equality of Angles belongs to two Right ones. Because it belongs to the Nature of God to be; neither can he be conceived without Existence. For would not something be wanting in God, in case he did not Exist? Or how otherwise could he be said to be a Being absolutely per-

fect? Since Existence is nothing else but the Reality of any thing, whereby it is placed out of Nothing, which therefore no Being absolutely perfect, can be supposed to be without. For as Cogitation presupposeth the Existence of the thing that Thinks; so likewise, absolute Perfection requires Existence; because an absolutely perfect Substance cannot be conceived, but as actually Existent, and unchangable from Eternity.

You will say: Tho' we cannot conceive a Mountain without a Valley, yet it doth not follow thence, that there is any Mountain in Nature, since a Mountain doth not include Existence: And therefore neither doth it follow that God Exists, because I conceive him as Existent. For there is no necessity laid upon things to Exist, from my Thought or Apprehension.

I Answer, That this Argument doth not proceed aright; for tho' a Valley enters the Conception of an Hill, and neither can be apprehended without the other, yet is it not inferred thence, that either a Mountain or Valley doth Exist; but that whether they Exist or do not Exist, they cannot be separated from each other. But seeing I cannot conceive God without Existence, I must conclude, that Existence is inseparable from him, and that therefore God cannot be conceived, but as Existent.

But you will further urge, that the Sun Existing doth essentially involve two things, viz. the Sun and the form of Existence, so that Existence belongs to this complex Notion of the Sun Existing. But Gods knowing this complex Notion from Eternity, doth not impose a necessity of Existing upon the Sun, without presupposing its actual Existence in the World. So likewise tho' Existence be contained in a Being absolutely perfect, yet cannot we conclude thence that it actually Exists, except we suppose it to include Existence, as well as the other Perfections.

I Answer, That in the Idea of an Existing Sun there is only a Possible, but not a necessary Existence contained; because we do not understand that actual Existence must of necessity be joyned with the Properties of the Sun; for tho' it be conceived as Existing, yet doth it not follow thence that it doth Exist; forasmuch as this complex Notion, the Existing Sun, may be framed by the Understanding; and that these two Notions may be separated, not only by Abstraction, but also by a clear and distinct Operation, so as that the Sun may be conceived without Existence. Whereas, in the Idea of God actual and necessary Existence is involved, which hath an inseparable Connexion with the rest of his Attributes. So that it is impossible to conceive an Infinite Being to have all Perfections, except it do actually Exist. For necessary Existence is the Property of God, which agrees to him alone, and makes a part of his Essence.

Wherefore, when we enquire, whether the Existence of a thing absolutely perfect can be inferred from its Idea, the Question is not, whether out of every Conception or Idea of a thing, we can Demonstrate its Existence; but only whether from the Idea we have in our Mind of a Being absolutely perfect, we may rightly conclude its Existence. For it is a Fallacy, when we bestow an Attribute, that agrees only to one Subject, upon all. Wherefore I do rightly and demonstratively conclude, that if necessary Existence be contained in the Idea of

VI. Objections.

VII. Answered.

VIII. An instance.

IX. The instance.

X.

of God, that is, if by a clear and distinct Perception, I cannot divide actual *Existence* from his Nature, God must necessarily *Exist*; by the same necessity that the Nature of Man doth consist of *Soul* and *Body*, and that a *Valley* includes the Conception of an *Hill*.

XI.
The Essence
of God is
not a Fig-
ment of our
Understan-
ding.

Some with whom I have Discoursed about this Point, deny the *Essence* of God to subsist any where but in our *Mind*, and that it is nothing else but a figment or thing feigned by the *Understanding*. But this is easily overthrown by shewing, that necessary *Existence* is not included in any Fiction of our *Understanding*. Besides, the *Essence* of God is either Possible, or Impossible; if they grant the first, it must necessarily *Exist*; for what other thing can impart *Existence* to a thing that is Possible? If they say it is Impossible, it will lye upon them to prove the Contradiction it implies.

XII.
The Ex-
istence of
God may
be proved
from the
Conser-
vation of us.

The *Existence* of God may also be proved from our continued *Preservation*. For seeing that a *Creature* hath no power to preserve it self, we must have recourse to some *Cause* that preserves it. *Time* we know is divided into many Parts, which are independent of one another; since a Thing under *Duration*, may every particular Moment cease to be; neither doth it follow, because it was yesterday, that it must be to day; wherefore there must be some *Cause* to preserve it, and as it were to produce it anew every Moment, which its self cannot do, no more than it could at first give its self a *Being*. For *Conservation* is not distinguishable from *Creation*, but only by Reason; neither is there any less power required to Conserve a thing, than to produce it: Neither can *Parents* do this, since they only procure some Dispositions in the Matter, to prepare it for the Reception of the *Soul*, and we may Live after they are Dead: Wherefore there must of necessity be some first *Cause*, which may not only create and produce us, but also keep and preserve us.

XIII.
How it is
to be under-
stood that
things can
not preserve
themselves.

If you oppose to what I have here alledged, the *Law* of Nature set down by *Des Cartes*: That every thing, as far as in it lies, endeavours to continue in the same State, neither is ever changed, except it be forced to it by a foreign Agent; and that according to this *Law*, every thing which *Exists*, must continue always to *Exist*, neither stands in need of any new force, whereby to be sustained in its *Essence*. I Answer, That whatsoever is besides God, is a *Being* depending on another; and whatsoever once essentially depends on another, must of necessity, for always so depend on it, because what is *Essential* admits of no change; and so great a *Virtue* is required in an *Independent Being*, that all things depend on it, as in the First Moment, so also in the Second, Third, &c. Wherefore when it is said, that every thing, as much as in it lies, continues in the same State; this must be understood with regard to the *Perfection* or *Nature* which hath been given to it, to which God who is constant and unchangeable, is supposed to afford his continual concurrence.

XIV.
An account
of what is
to be hand-
led in the
following
Chapter.

Tho from the *Idea* we have of God, and from the Contemplation of him, and our own Conservation, his actual *Existence* is evidently deducible; nevertheless we will also endeavour to make out the same from all Sensible Objects. This was not undertaken by *Des Cartes*, forasmuch as he being chiefly intent on the *Idea* of God, had not yet disco-

vered Material things, and therefore could not properly alledge any Argument from their Production.

CHAP. IV.

The Contemplation of the World proves the Existence of God.

Almost all the Philosophers that ever duly considered the Miracles of Nature, constantly acknowledged an Eternal Godhead, by whose out-breathing all things are Quickned, and receive Life and Heat. For who is there so stupid, who from the Stupendous Structure of the World, the continual Rotations of the Heavens, and the never discomposed order of Nature, doth not necessarily infer, that there is a Supreme Creator, who doth govern the World, as *Boethius* saith, by Perpetual Reason, at whose command Time is, and who being Stable, and Immoveable himself, imparts Motion to all things? What else doth the vast extent of this World, the variety of things therein contained, the Beauty of its Parts, the constancy of its Motions Preach to us, than that there is a great Moderator, who is the Author of this Transcendent Structure, and the Original disposer of this Harmonious Order?

We all are link'd to God, a silent Breast,

His Temple is.

What is the Place of God but Heaven and Earth

The Air and Seas, to which he's given Birth?

What but a Vertuous raised holy Mind?

Where if we can't, we'll scarce him elsewhere find.

All that thy Gazing Eye doth see, and all

That doth thee move, is that which God we call.

Lucan. lib. 9.

I will own that some mean Philosophers, may rest in the Contemplation of Second Causes, and entertain their Minds with the consideration of Natural Objects, without looking further. But it is impossible, that he who attentively considers their Subordination, and diligently weighs their Connection, should not be forced to own a Creator of Heaven and Earth, and acknowledge his perpetual Providence, except (as *Aristotle* saith) he be so unhappy, as to be fallen into the deepest Gulf of Blindness and Misery. But that we may illustrate this a little by an Example, Let us suppose that *Protagoras*, or some other Atheist, had got a view of *Archimedes* his Glassy Sphæra, in which the Heavens, I say, perform their several Motions, where the Sun and Moon do by degrees withdraw themselves towards the East, and being hurried along by the *Primum Mobile*, are whirled about, within the space of Twenty four hours; Do you think that *Protagoras* would have believed this Machine, to have been jumbled together by Chance, by a Fortuitous Concurrence of the Parts, and not much rather that it was the effect of Art, and of the Brain of a most Subtil and Accomplish'd Mathematician? For seeing it doth chiefly belong to an Intellectual Agent, fitly to adapt divers things, and to dispose them according to his designed end, he will be forced to confess that such an accurate and ingenious

genious piece of Work, must have proceeded from Reason, and not from a Chance-medley of Atoms.

III. But if it be lawful to compare Great things with Little, and Weak things with such as are Perfect, what is Archimedes his Sphear in comparison to this Universe? How much more Perfect is the Original, than the Copy? And shall we believe that Archimedes, in his Imitation of the Motion of the Wandring Stars, made use of Reason, and at the same time suppose, that this infinite number of Stars, this wonderful adorning of the Heavens, this excellent Order of an unutterable variety of Works were the product of casually jumbled and julted Atoms? This can never be supposed by any one in his right Wits: And he that hath either outward Eyes to see with, or an Understanding to discern, can never submit to what is so contradictory to Sense and Reason. For this cause I suppose it is, that GOD, who disposeth all things in Number, Weight, and Measure, and who takes so great Care for Mankind, yet hath never been known to work any Miracles in favour of Atheists; because the Workmanship of Nature is not only a convincing Argument of his Power, but doth also strongly invite and persuade us to the highest Admiration of all his Divine Perfections. And to speak the truth, I could much more easily believe all the Fables of *Aesop* for true Histories, and that Mice had conferences together, and that a Weasel entertain'd a witty Discourse with the Fox, than that the Rising and Setting of the Stars, the Vicissitudes of Day and Night, the variety of Seasons in the Fourfold divided Year, the two *Aequinoctials*, and as many *Solstices*, could ever have been so ordered, without the Divine, that is, the most Perfect Reason; or preserv'd in the same, by an invariable and uninterrupted Succession. For do not all these, and all the other Wonders, with a constant and never ceasing Voice seem to proclaim, that they are the Off-spring of an Invisible Sovereign Power, and by no means their own Artificers? He hath made us, and not we our selves.

IV. But that I may not insist too long in laying open the Beauty of the Universe, I will pass by the vast Globe of the Earth, poised in the midst of the Air, the Mountains lifting up their Heads towards Heaven, the Rivers that water and fructify the Earth, the prodigious variety of Vegetables, which grow of themselves, and the vast number of Mines and Quarries, from which Gold, Silver, and the rest of the Metals, with several sorts of Earths and Stones are dug. Let us only consider, the almost infinite differing kinds of Living Creatures, whose opposit outward shape, and the great and many Conveniences and Necessaries they afford to Mankind, declare them to be the effect of the One only First Principle or Author of all things. For who can imagin that the difference of Male and Female, the desire of Mutual Embraces, and of perpetuating themselves by their Posterity, and Organs fitted for that purpose, were design'd and contriv'd by any thing less than a Wise Omnipotence? Who is there, that upon a diligent view of the several sorts of Birds, their astonishing Artifice in making their Nests, their Hatching and care of Feeding their Young, their dexterousness in teaching them to Fly, doth not

presently discover the Supreme Cause of them, who with wonderful Wisdom and Artifice hath contriv'd and order'd all things, and hath imparted several virtues and forces to different Animals, according to their various use and capacity? How exquisitely is their whole frame suited to the use for which they are design'd, and how accurately are their Organs adapted to their several Actions? Thus Bulls are furnish'd with Horns; Lions with their Paws; Elephants with their Teeth and Snout; and the Rhinoceros with his close Armour, as well in order to the attaining of their designed End, as to defend themselves, and offend their Enemies.

Shall any one be so weak as to think, that broad and flat Feet were given to Water Fowl without any design, and by meer hap hazard, when the use of them in Swimming is so apparent? Can any one suppose that Hens should by chance, have long Legs and Necks, and Beaks sharp pointed like Daggers, wherewith they pierce the Fishes, and draw them out of the Water for their prey? Whence hath the Pike his prominent Saw-like Teeth on each side his Jaws, and the Roof of his Mouth thick set with Hooks, that the slippery Prey might not escape his greedy Jaws? Is it by chance that the Woodpecker is furnish'd with Claws, wherewith it runs up the side of Trees like a Cat, and a forked Tongue, wherewith it robs the Tarantula of her Prey? Consider the Arts and Industry of the Bees, Pismires, and other Beasts, about their Food, begetting of their Kind, breeding of their Young, and fighting with their Enemies, and it will appear self-evident, that none of these can be supposed the fruit of an Accidental and Confused motion of Atoms, forasmuch as nothing more excellent, more apposite or useful, can be conceived by the Mind of Man.

But to make no longer stop here, let us take a view of Man, Nature's Masterpiece, and behold all the Excellencies dispers'd up and down in all other Living Creatures, united in this Microcosm, or Little World. Can any one behold his comely Form, the erect posture of his Body, his Face looking upwards, and (as it were) directed towards Heaven, and the Beautiful symmetry and proportion of his whole Body and Parts, and suppose him to have had no Author of his Being? But to leave the Wonders of his Outside, if we proceed to take a view of his Inward Parts, their structure and situation, the Nerves and Sinews deriving their Original from the Brain, the Arteries from the Heart, the *Aethereal* ever moving Spirit that fills them, and imparts motion to all the several Joints and Members of the Body, and vigour and strength to perform all manner of Actions, we shall find still stronger Arguments to persuade us, that there must be a First Cause, who is the Principle of all Human Perfection.

But forasmuch as Vulgar Wits are more apt to be taken with Examples than Discourse, let us take to task some one Part of the Body of Man, for Example, the Eye, and scan the Miracles it contains. And here at first sight we meet with so many Wonders in its most curious Make and Contrivance, that it is impossible for a Man, not wholly bereft of Reason and Understanding, to doubt of the Sovereign Perfection of the Artificer. In running over its outward Parts, we meet with the

Bony

Bony Orbit, or round *Ossa Orbita*, together with the *Eyelids*, the *Hair* of the *Eyelids*, and the *Eye-brows*, as also the *Glandules* or *Kernels*, with the *Excretory Vessels* and *Passages*, all which serve either to defend that tender Part, or assist and facilitate its *motion*. The *Eyelids* are as *Curtains* to the *Eyes*, and are assisted with the ministry of several *Nerves*, which by infertion into the *Muscles*, become useful for the opening or shutting of them. The *Eye-brows* and *Hair* on the *Eyelids*, are like *Ramparts*, to secure the *Eye* from things that are hurtful to it, and to prevent their sudden and unexpected eruption. The *Excretory Passages* serve to carry off the superabounding *Humor*, that the *Eye* may not be clog'd by the affluence of *serous Matter*, or the *Eye-sight* dimmed by the acrimony thereof.

VIII. If we proceed to the Inner Parts, which Nature hath hid from, but Anatomy lays open to us; we shall first find the *Muscles*, wherewith this miraculous little *Globe* continues hung up and equally poised within the *Orbit*, and performs its various *motions*. In the Midst of it is the *Pupilla*, or *Sight*, of a round *Figure*, that the visible *Species* or *Rays* proceeding from *Objects*, might be the better received by it, from what part soever of the *Hemisphere* they come. After these appear the *Coats*, or *Membrans* of the *Eye*, and next the *Humors*, which like a *Dioptrick-Glass* do refract and concenter the *Rays* that represent the Images of *Bodies*. For the *Watry Humor* distending the *Membran*, and making it gibbous, doth ampliate the *Convexity* of the *Eye*: And the *Crystalline Humor* placed within the opening of the *Grape-like Coat*, *Tunica Uvea*, like a piece of *Glass* set opposite to a *Hole*, in which the *Rays* coming from all parts are collected and refracted. And behind the *Crystalline Humor* is placed the *Glassy Humor*, by means whereof the *Tunica Retina*, or *Network Membrane* is at a fit distance separated from the *Crystalline Humor*, so that when the *Rays* with due refraction have past the same, they attain their proper place and center.

IX. Tho' the *EAR* be not of equal use and concern to the convenience and necessities of *Life*, as the *Eye*, and is only design'd for the perceiving of *Sounds*; yet is it for the Excellence of its structure very little inferiour to that of the *Eye*, especially if we consider its Inner parts, and the mutual connexion of them. For from the *Lappet* of the *Ear*, which is narrowed by degrees, we see that the *Hollow* of the *Ear* goes slanting inwards, to the end that the *Sounds*, by passing its crooked Windings and Turnings, might be encreased. For the thin *Membrane*, placed near the *Hole* of this inward Cavity, being struck by the impuls'd *Air*, doth affect the *Fibres* and *Auditory Nerve* with the same motion. There are also three small *Bones* fitly disposed and tied together with a *Ligament*: The first of these is call'd the *Hammer*, because of the resemblance it bears with that Instrument; the second is call'd the *Anvil*, which is somewhat roundish; and the third, the *Stapes* or *Stirrop*; they are moveable, and seem to be of good use to defend the *Drum* of the *Ear*, and prevent its being too much slackened, or too stiff bent. From the fore-mention'd *Hollow* of the *Ear*, the Passage (commonly called by *Anatomists* the *Oval Hole*, or *Window*) opens into the *Labyrinth*, and so leads

to the last *Inner Cavity*, called *Cochlea*; because in its *Spiral Windings* it resembles a *Snails Shell*, which if well view'd, appears to be the work of admirable Artifice; for being form'd with such Turnings, it renders the *Sounds* more distinct, and causes that there be no confusion of them. Besides, there are many other Parts not here to be insisted on, whose wonderful Contrivance does much conduce to *Hearing*.

Now who can be conceived so stupid and void of all *Judgment*, as to think that the *Organs* of these two *Senses* were made by a fortuitous jumbling together of small *Bodies*; and not rather acknowledge the most *High God*, who by his inimitable *Wisdom* has so curiously framed, and orderly disposed all these several *Parts*, that nothing can be imagin'd more adapt, and better suited to the uses for which they were designed.

I could never approve of *Democritus* his Opinion, which attributes the Original of the *World* to a company of justling *Atoms*, as if their Roaming vagaries were an adequate Cause to produce all the *Bodies* in the *Universe*. For how can we suppose, that in that infinite Space, wherein he asserts his *Atoms* to be toss'd, they should come together and unite, to the framing of all the *Parts* of *Living Creatures*? Can we imagine, that by the huddling concourse of like *Bodies* so many *Nerves* and *Muscles*, so many *Ligaments* and *Tendons*, so many *Filaments* and *Fibres*, could be formed? Can we think that the *Legs*, *Shins*, *Feet*, *Toes*, *Joints*, with all the other *Organs* of the *Body*, were the effect of blind and impotent *Chance*? Can we conceive that the *Heart*, that Noble *Muscle*, and the *Breast* in which it is contain'd, together with its *Ribs*, *Muscles*, the *Lungs*, and the *Midriff*, were made without a Cause and at Hap-hazard? Or that such a vast number of *Veins*, *Arteries*, *Giffls*, and *Membrans* had no other rise, but meer *Chance* and the Heaviness of *Bodies*? Who can force himself to imagine, that an infinite number of *Blind Men* plac'd in an open Field, by a confused running in amongst one another, should at last produce an *Army* orderly drawn up in *Battle*, according to the most exact Rules of *Military Art* and *Discipline*? Or why may not we as well with *CICERO*, suppose that a vast number of *Alphabetical Characters*, being casually thrown upon the *Earth*, should all rank themselves into *Lines* and *Words*, making the *Annals* of *ENNIUS* the Poet? Now as no Man can so much over-bear his *Reason* as to think this possible, how much less will he be able to believe, that the curious Structure and Order of the *Parts* of *Animals*, is the effect of *Chance*, that is, of no Cause at all?

And to deduce this matter from the Beginning of the *World*; If it be so that *Atoms* have a Power to produce and generate things, why do they not now produce or renew the same Things they framed so long ago; why are there no *Mountains* rais'd anew? How is it that they do not constitute another *Sun*? How it comes to pass that all *Living Creatures* keep to their kinds, and that no new ones do arise from their Senseless Jumbling together? Neither will it be of any advantage for the *Atheist* to alledge here, that *Flies*, *Mice*, and other *Insects* are daily generated without the Union of both *Sexes*; because the Question here is not concerning the Production of Things, but

concerning the inborn Power of Nature, or *Seeds*, out of which *Living Creatures* are Born, and are endowed with a *Virtue* fit for the *Generating* of them. And seeing they have not this of themselves, since it is a contradiction for a thing to be productive of it self, it must follow that they are the effect of the *All-wise God*, by whose power they act whatsoever they do.

C H A P. V.

Concerning Fate and Will, or the Divine Decree.

I. The Ancients took great Pains to reconcile the Divine Preordination with the Liberty of Mans Will.

THE Ancients were so solicitous of Preserving Human Liberty, that when they found they could not reconcile them with some of the Divine Attributes, they chose rather to acknowledge their own Ignorance, than to deny it. For when they found that all our Actions must be pre-ordained by God, forasmuch as he is the All-knowing Governor of the World; and on the other hand experienced in themselves a Freedom of Will, they admitted both to be True, viz. that God doth pre-ordain all our Actions, and that we nevertheless enjoy Liberty of Will. But when they afterwards proceeded to enquire further, how it could be, that Mans Liberty standing, God could have fore-ordained all things from Eternity, they ingenuously profess their Ignorance, and that it was no wonder, that an Infinite Being could not be Comprehended by a Created Understanding. This acknowledgment of Human Frailty was certainly praise-worthy in them: But forasmuch as all are not satisfied with this Answer, many being solicitous to know how the Liberty of Man may be reconciled with Gods Decree, I suppose it will not be useless to make out, that Gods Foreknowledge of and Foreordination of Human actions, doth not take away the Liberty of them.

II. What Fate or the Divine Decree is.

And here if we consider the Nature of Fate, or the Divine Decree, we shall find it to be nothing else, but what God hath determined concerning every one of us: Or it is the Eternal Decree of his Providence, by which he Sees, Knows and Governs all things. And as BOETHIUS expresses it; Fate is an Order or Disposition, Inherent in changeable things, by which Providence links them to their due Ranks and Orders.

III. Fate lays no necessity upon Human Actions.

Now that this Order or Disposal doth impose no necessity upon Human Actions, is apparent, because we find that it is in our Power, to give our Assent to, or to Dissent from many things, and after having ballanced both parts, to choose one, and reject the other. We see likewise that Men frequently change their Minds at the Persuasions of their Friends, and do refuse what first they had embraced. And indeed were it otherwise, all Prudence and Reason in Mens ordering of their affairs would be taken away; for if they had no Freedom to chuse that part, to which they are inclined by Rational motives; they would not act by the direction of Wisdom, but by Chance and Fortune.

IV. It is an Argument of our weakness, that we cannot reconcile Gods omnipotence, with the liberty of our will.

And what can be more absurd than to go about to deny our Liberty, which we experience in our selves, and whereof we are so fully Conscious, that nothing can be more illustrious by the Light of Nature than it is, because we can scarcely reconcile it, with the Divine Omnipotence and Providence? We ought ever to remember that we are Finite, and that God is Infinite; and that our Li-

berty must not presently be denied, because we cannot conceive it inconsistent with the Will of God, which is without us, and which our Minds are not able to comprehend; forasmuch as this only proceeds from the weakness of our Wit and Understanding.

'Tis true indeed that Fate is immoveable, but yet so as that it inheres in things that are moveable; because it doth not take away the Nature or inbred Motions of things, but moves them sweetly and without any manner of constraint; according to the Requirings of the different Nature of things, so as to act necessarily, with things necessary, and freely with free and voluntary Agents.

Neither is this Assertion overthrown by that common Objection: If God foresees that I shall Sin, seeing that his Foresight cannot be deceived, it follows that I must necessarily Sin. For God doth not foresee my Sinning necessarily, but freely and voluntarily; and his Knowledge imposeth no necessity upon my Actions, no more than my knowing that Peter will walk to morrow, doth lay a necessity upon him of doing so: Or than the knowledge I have of the Suns Existence in the Heavens, doth cause the Sun to be there.

For what can be more Childish than to think, that the Foreknowledge of God, which is altogether External to the thing known, should put a force upon the Will of Man? But you will say, God cannot be deceived. And what then? Consequently, you'll say, it was either true from Eternity, that you were to recover of this Sickness, or else false: Therefore it is in vain to make use of a Physician, since neither the necessity of Fate, nor Eternal Truth can ever be changed. This is worthily stild by CICERO to be a lazy Question, because by the same Argument you may overthrow all Human Actions. But that Gods Foreknowledge, doth not import any necessity is evident from this; that a Contingent thing is of its own nature Indefinite, and of a doubtful event, tho' with respect to the Divine Foreknowledge, it be Definite and determined.

AMMONIUS illustrates this by the Example of a Globe, resting on the Plain of the Horizon, the indifferency whereof as to Rest or Motion, doth well express the indifferency of our Will; but if this Plain be never so little inclined, then it must move of necessity: So likewise when the Will is inclined to any thing, this makes a kind of necessity, upon Supposition only, that the Will turned it self this way; or that God did foresee this inclination from Eternity.

You will say, Gods Prescience is most certain; therefore its Object cannot but come to pass; and that which cannot but come to pass, is therefore necessary: Therefore, Gods Foreknowledge imposeth a necessity on the Will. I Answer, by distinguishing the Consequent; I grant that the thing which is the Object of the Divine Foreknowledge, cannot but happen upon Supposition, that it is to happen so, from a necessity of Consequence; but I deny that it cannot but come to pass absolutely, and by a necessity of Antecedence.

There is a two-fold necessity, the one Antecedent, and that is that which is the Cause of the Action, which necessity the Will cannot resist: The other is Consequent, which is not the Cause of the Action, but doth presuppose it, and is consequent to it. And it is this latter only which is brought upon Human affairs, by the Divine Prescience: Foraf-

V. The Decree of God doth suit it self and comport with things.

VI. Gods Foreknowledge lays no necessity or force upon Mans will.

VII. The knowledge of God being external to the thing known, cannot hinder its Liberty.

VIII. The certainty of Gods Foreknowledge is no Argument for a force upon our will.

IX. There is a two-fold necessity.

CHAP. VI.

How God is said to be the Cause of Propositions of Eternal Truth.

I.
How the
Essences of
things are
distinguish'd
from their
Existency.

For the better understanding of this Question, we are briefly to presuppose, that the *Essences* of things are modally distinguish'd from their *Existency*: For we understand the *Essence* of a thing after one manner, when we abstract it from *Existence* or non *Existence*; and after another when we conceive it as *Existing*. For a thing is understood to be *Existent*, when it is *without our Understanding*: But a thing that doth not *Exist*, is *objectively* in our Understanding, and is not *without our Thought*. Of this kind are *Eternal Truths*, viz. That a Triangle hath three Angles equal to two right ones: Six and Four make Ten; and such like, which are considered as *Ideas* in our *Mind*. And forasmuch as these *Ideas* cannot be said to be nothing, but something, the Question is, what is the cause of them, that is, whether they depend on the Understanding of Man forming them, or whether they owe their production to some other Principle.

II.
God is the
cause of
Propositions
of Eternal
Truth.

I Answer, that all *Eternal Truths* are from God, as from their efficient and total Cause; for he is the Cause of all *Creatures*, not only as to their *Existence*, but also with regard to their *Essence*. Forasmuch as he being *Infinite Goodness*, could not be impelled by any other Reason of *Goodness*, to do that which is best: But on the contrary because he determined himself to produce the things that are, therefore they deserve the Title of being *Good*. As for Example, he did not therefore will the three Angles of a Triangle to be equal to Two right ones, because he saw, that they could not be otherwise; but on the contrary, because according to his *Free-will* he had determined the three Angles to be necessarily equal to Two right ones, therefore they could not be otherwise. For in God to Will, to Understand and Create are one and the same thing: Wherefore because he knows a thing, therefore it is true.

III.
The non-
Existence of
God being
supposed
nothing is
less true.

Neither can we say, that these *Truths* would be no less true, whether God be supposed to *Exist* or not: For this is most false; because all *Truths* depend upon the *Existence* of God, who is the first *Eternal cause* of them, from whence they all flow as from their Fountain. Neither is this difficult to be conceived, if we consider God as an *Infinite, Eternal, Incomprehensible Being*, the *Author* of all *Good*, and on whom all things depend. And therefore they are in a great Error, who think that any thing can be independently of his *Will*.

IV.
That twice
four make
eight is
from God.

Neither doth it oppose what we have said, that the *Mind* of Man cannot conceive the three Angles of a Triangle not to be equal to two right ones; or that twice four should not make Eight: For to prove this, it is sufficient to shew, that there can be no *Being* which does not depend on God, and was not freely constituted by him: For this being laid down, it evidently follows, that it was not always necessary, that the three Angles of a Triangle

should be equal to two right ones, or that twice four should make eight, but that it was so constituted by God.

For seeing God is positively of himself, he is endowed with such an *Essence* and *Nature*, that from the consideration thereof we can assign a Reason for *Eternal Truth*, without need of having recourse to any other Object, for the clearing of their Evidence and certainty. This *Attribute* would agree to some other besides God, if we should suppose some *Natures, Truths* and *Essences* to be such as to be independent of God. Because if any one should demand why they were such, and whence they had their *Truth*, it might be answered, that they were *Eternally so of themselves*, and that for that Reason, they became the Objects of the *Divine Knowledge*, as being of themselves Antecedent to it. Which is so derogatory to the *Divine Omnipotence*, that it is a wonder to me how any can assert such a thing, who consider well the *Divine Independency* upon any things whatsoever. Forasmuch as it would follow from hence, that the Complement of the *Divine Cogitation* would not depend on the sole understanding of himself, but also of some other thing, which was not of the *Nature* of God, and which is conceived as independent on his *Will*.

If you Object that the *Essences* of things are *Eternal* and *Immutable*; I answer, That they are so indeed, if it be understood concerning the *Immutability* and *Eternity*, which God hath prefixt to them, whilst by his *Free-will* he has determined some things to be *unchangeable*. Or else it may be said according to the Sense of the *Vulgar*, that the *Natures* of things are *Eternal*, because there was no Time before them; or rather because the *Eternal God*, doth conceive them without Succession, neither will suffer them for ever to cease or be changed.

GOD therefore is the *Efficient Cause* of all things; not only of such as *Exist*, but also of *Possibles*, and of all *Truths* that we call *Eternal*: In like manner as a King is the Maker of all the *Laws* in his Kingdom. For all these *Truths* are inborn in us from him; as a King also would have them so in his Subjects; if he had Power enough to write his *Laws* in their Hearts.

If any one say, That this would make God inferior to a King, who can at his Pleasure annul the *Laws* he has made; which if God should do, those *Truths* would lose their *Essence*; and consequently would be no longer *True* or *Immutable*.

I Answer, That the Case of God and a King are very different. A King can change his *Laws*, because his *Will* is changeable, but God's *Will* is unchangeable; for it is his *Perfection*, that he acts in a most constant and invariable manner. Neither doth it hinder this that his *Will* is free; for as his *Will* is free, so likewise is his *Power* Incomprehensible. Wherefore tho' I cannot comprehend how it should not be true, that One and Five are Six; yet I understand clearly enough, that it is impossible there should be any thing in the whole *Universe* of Things, which does not depend on him. And therefore it is contrary to Reason to think that any thing cannot be otherwise, because we cannot understand how it can be. It is indeed true in the general, that GOD can do all those things, which are clearly and distinctly known by

us; yet doth it not follow from thence, that he cannot do those things that we cannot conceive: For our *Imagination*, or *Understanding*, cannot be the Rule of his *Power*. Therefore we must conclude, That the *Essences* of Things, and *Mathematical Truths* are from God, because he so conceived them; so ordered, and so commanded them: According to that of *S. Austin*; *Because thou seest them, (or rather, because it listeth thee) therefore they are.*

C H A P. VII.

Concerning the Divine Attributes; and, First, Of the Unity of GOD.

I. *What the Attributes of GOD are.* **A**ltho' GOD be One meer *Cogitation*, and all his *Perfections* or *Attributes* indivisibly United; yet the Acts of *Cogitation* that we have of him, stir'd up from several Occasions, which frequently involve many *Objects*, are Many. For when I consider, that my *Mind* doth not exist of it self, neither can do all, nor understand all things, &c. I turn my self to the *Divine Cogitation*, which comprehends all *Perfections*. And these *Reflexions*, whether as referr'd to God, or to the various Conceptions of *Objects*, are called *Attributes*. Whence it comes to pass, that one of my *Cogitations* I have of God, as *Existing*, is different from another *Cogitation* I have of him, as *All-powerful*, or *Eternal*: Because the occasions of these my Thoughts are different; and one *Object* which I refer or apply to God, is different from another which I can likewise apply to him. Wherefore seeing I do not find my *Mind* to be one only, but perceive also the *Idea's* of other *Minds* of the same Nature with mine, I cast my Eye on the *Divine Cogitation*, and thence take an occasion of considering its *Unity*.

II. *The Divine Attributes are indivisibly united.* If therefore we consider the *Essence* of God in it self, it appears to us to be one *Simple*, *Uniform* *Cogitation*, exempt from all *Order*, *Distinction*, *Priority*, or *Posteriority*. Forasmuch as all the *Perfections* that are, or we can think of in God, are not only actually present in his *Nature*, and inseparably united with it; but are so intimately joyned, that the one is the other; yea, that one of them is all the rest, and All are most properly One in their *Essence*: So as that his *Eternity* is his *Omnipotence*, his *Life*, his *Spirituality*. In a word, All his *Attributes* are his *Life*, and his *Life* is all his *Attributes*.

III. *The Unity of GOD was known to the Ancients.* It was the constant Opinion of the *Ancients*, That GOD is One only; the Sovereign of the *Universe*, whom all things obey. Both *Poets* and *Philosophers* own'd this, who frequently call him, *The Maker of all things*, *The Ruler of the World*, and *The Mind diffus'd through all things*. Wherefore also they gave him no peculiar *Name*, as supposing that no *Title* could be given to him, who was singular, and had nothing common with other things; for that *Names* were only necessary where *Plurality* is to be distinguish'd, and persons discriminated by certain Marks.

IV. *The Divine Senses, we are to enquire first, in what respect God Unity is to be explained.* But because the word *Unity* is taken in divers Senses, we are to enquire first, in what respect God Unity is to be explained.

V. *A thing is* A Thing is said to be one, *First*, when its *Parts* are united; yet so as that it may be divided into

them; as a *Body* is said to be One, because of the *Union* of its *Parts*, tho' they be separable. Secondly, A Thing is said to be One, because it hath one *single Essence*, which cannot be divided into *Parts*; tho' the *Attributes* and *Modes* wherewith it is diversified, may be separated from it, such as *Knowledge* and *Vertue*, without which the *Soul* of *Man* may be. Thirdly, a Thing is said to be One, which is so undivided, that it can in no respect be divided, nor hath any *Attributes*, or *Modes*, that are separable from it, but all things appertaining are most simply one.

VI. In this last meaning God is said to be One, because all that is in him is One, neither hath he any *Attributes* that are not *Essential* to him, and inseparable from him. And therefore according to our *Philosophy*, the *Divine Attributes* are only *Modes* of *Thinking*. For when we distinguish his *Will* and *Understanding*, that distinction is only made by our *Minds*, as we conceive him to be conversant about *Goodness* or *Truth*. But *Real Modes* are found in the Things themselves, which they affect and distinguish from others; as *Figure* and *Motion* in *Bodies*; *Willing* and *Understanding* in the *Mind*. And are therefore call'd the *Modes* of *Things*, because they agree to mutable Things, such as all *Created Beings* are; but not to a *Being* that is constant and ever-abiding, such as God alone is. Wherefore whatsoever is in God is only distinguishable by reason.

VII. Having shewed what manner of *Unity* agrees to GOD, it may further be queried, Whether God be one in such a manner, as to suffer or admit none besides him. To which I answer, That God is One in such a manner that he cannot be multiplied: For seeing by the Name, GOD, we understand a most *Perfect Being*, it is necessary that it comprehend all that is most *Real*; so that supposing him to exist, all conceivable *Perfection* must be placed in him, so as by his *Idea* and *Essence* formally to exclude every most *perfect Being* besides himself. For indeed how can any be equal to him? Or how can all conceivable *Perfections* be in two several *Subsistences*; seeing that whatsoever admits of *Division* is subject to *dissolution*, which is the most remote from the *Nature* of God, who is *Incarnate* and *Eternal*.

VIII. If it be said, That this *Division* is no hindrance to their *Immortality*, as long as the one doth not arrogate any thing that belongs to the other, but each of them follow their own work. It will still come to the same thing; for this distribution of their *Work* or *Business*, is an evident Instance of great *Imperfection*; because this supposeth them to stand in need of one anothers assistance, being unable all alone to govern the *World*; which is contradictory to the *Divine Essence*, which is known to be *Omnipotent*, *Infinite*, and *All-wise*.

IX. Moreover it is most certain, that supposing a *Plurality* of Gods, they cannot be every way equal, but that some *Perfections* would be found in the one, which are not in the other, which is altogether incompatible to the *Supream Being*. For let us suppose two Gods, whom for the greater clearness of Discourse, we will call *Saturn* and *Jupiter*. Now these two Gods, forasmuch as they severally include all *Perfections*, they must of necessity be *All-knowing*, so as not only to know themselves, but others also; and because in the *Idea* of either

of them, necessary *Existence* is included, it will follow, that the Cause of the Necessity and Truth of the *Idea* of *Saturn*, which is in *Jupiter*, will be *Saturn* himself; and the Cause of the Truth and Necessity of the *Idea* of *Jupiter*, which is in *Saturn*, will be *Jupiter*; and therefore some Perfection will be found in *Saturn*, which is not in *Jupiter*; and in *Jupiter*, which is not in *Saturn*. The reason whereof is this, because the Perfection of the understanding of either of them, will depend on the other; and so must be both of them Imperfect, which is repugnant to the Nature of a most perfect Being.

X. It belongs also to the *Idea* of a most perfect Being, that he be *All-powerful* and *All-knowing*; but it is a Contradiction, that more Beings than one should be endowed with these Perfections: For either they would be able to hide their Thoughts from each other, or not be able; if the first, how could they both be *Omniscious*? If the latter, how could they be *Omnipotent*?

IX. Lastly, Necessary *Existence* is included in the *Idea* of *God*, because he is *Independent* of, and before all other Beings. Now whatsoever doth necessarily exist, must of necessity be Singular, since Singular Being is nothing, but actually to exist, which is so peculiar to *God*, that he cannot but exist: Wherefore seeing Singularity and Unity are one and the same thing, it is evident that the *Divine Nature* excludes all Multiplicity, that is, cannot be divided into more *Gods*; and consequently, as *God* is *Undivided* in himself, so neither can he be partible into others.

XII. But may some say, How comes it to pass then that the *Heathens* worship'd many *Gods*, if it be so that more *Gods* than one implies a Contradiction? I answer, That the *Heathens* never had any *Idea* of many Beings absolutely perfect, as is evident from their Writings; because they made one to Rule in *Heaven*, another in *Hell*, a third over the *Winds*, a fourth over the *Fire*, and distributed the Government of the *Universe* amongst many *Gods*: But they did not suppose any of them to contain all manner of Perfections, and to have the Power and Dominion over all *Creatures*; but took them to be much of the same Nature as we conceive the *Angels*. And *Marsilius Ficinus* tells us as much, *Argument. in Cratylum*: Neither let it trouble you, saith he, that *Plato* doth frequently make mention of many *Gods*: For he proves in his *Parmenides* and *Timæus*, that there is but One *God*; and that the rest are only his *Angelical* and *Heavenly Ministers*; and by calling them *Gods*, doth not so much imply their being *Gods*, as their being *Divine*. For indeed the *Philosophers* do so much abhor a Plurality of *Gods*, that it would be more easie to persuade *Euclid*, that many *Centers* may be found in a *Circle*, than to make *Philosophers* believe that there are more than one *God* in the *World*.

C H A P. VIII.

That *GOD* is *Eternal*, or without *Beginning* and *End*.

I. The Error of some, who say, that *God* was the

THo' almost all *Philosophers* agree in this, that there is a *GOD*, and that he governs the *World*; yet don't all of them conceive his *Existence* after one and the same manner. Some of them are of Opinion, that *GOD* had some kind of

Beginning, and tho' the same were before all Ages; yet that he was born or produced as all other Things. But forasmuch as it was unbecoming the *Divine Majesty* to proceed from any other, and that he who is the *Author* of all Good, should derive his Being from another, they asserted him to be his own *Efficient Cause*, and that he so proceeded from himself.

But this Opinion does not so much oppose Reason, as it destroys the very Nature of *God*: For how could *God* produce himself, since this supposeth that before his Production he was not, because he was then to be produced, and yet was at the same time, forasmuch as he did then influence his own Production, which are absolute Contradictions. And whatever may be said in this case, we must allow some Principle of the *Divine Production*, which is absolutely repugnant to the Nature of *God*. For we no sooner consider the Nature of *GOD*, but we find him to be the Most perfect Being, which excludes all Imperfections, that is, any bounds or limitation of his Perfections, and includes all Perfections, and consequently also *Existence*, by which he is distinguish'd from all other things.

For tho' whatsoever we conceive be apprehended by us as *Existing*; yet we find that *Existence* doth not belong to *God* and the *Creatures* in the same manner. For in the Conception of *Creatures*, whose Perfections are finite, only *Contingent* and *Possible Existence* is contained; whereas in the Notion of *God*, *Necessary Existence* is included, as being an *Eternal Perfection*; insomuch that it is as obvious to our knowledge that *GOD* exists, as it is to a *Mathematician*, that a *Triangle* hath three *Angles* equal to two right ones. For as it is the Nature of a *Triangle* to have three *Angles* equal to two right ones; so likewise it is the Nature of *God*, to be necessarily *Existent*, and therefore as he exists now, it must be acknowledg'd that he hath existed from all *Eternity*.

They who do not mind this, are very liable to Error, and to ascribe to *God* simple Duration instead of *Eternity*: For by distinguishing *Existence* from *Essence* in *God*, as in other *Created Beings*, they imagine Succession of Time to have place in him, and by this means divide that which is Infinite, into Parts, and assign differences of Duration to it. Hence it is that some demand, Whether *God* hath not existed longer now, than when he first Created the *World*; or whether he did not exist longer before the Creation of the *World*, than the Time that has run from the Beginning of the *World* till now. Which Questions are occasion'd by their separating the *Essence* of *God* from his *Existence*, and supposing that the *Eternity* of *God* may be understood, without the contemplation of his *Essence*; or because they have not distinguish'd Duration from *Eternity*, but have concluded them to be confounded together. For Duration is an Attribute of the *Existence* of things, not of their *Essence*. Who will not say that the Propositions, *Twice three make six*; *Nothing is made out of Nothing*; which are only said to be true according to their *Essence*, that they have continued longer now than at any other time? Wherefore Duration is only an Affection of *Existence*; whereas *Eternity* cannot be conceived without the *Divine Essence*; and forasmuch as the *Existence* of *God* is contain'd in the Conception of his *Essence*, we are also to attribute *Eternity* to him, and not Duration.

Efficient Cause of himself.

II. This Opinion destroys the Nature of God.

III. Necessary Existence is contain'd in the Nature of God.

IV. They who distinguish God's Essence from his Existence, take away his Eternity.

V. The Nature of God includes no Conception of Futurity.

Therefore we say, that all Creatures Enjoy Existence, forasmuch as it doth not belong to their Essences, but is in a manner foreign to them. But this cannot be affirm'd of God, because his Existence is not distinct from his Essence, and is GOD himself. Besides, all Creatures, whilst they enjoy the present Time and Existence, may be said to have it to come, forasmuch as their Existence is without them, and only successively bestowed upon them: Whereas we cannot say of the Divine Existence, that it will be, or is to come, because he has now the same Existence he will have for ever; Actual Existence in him being like all his other Attributes, which denote no difference of Time in Him.

VI. Whether the Mind of Man hath a permanent Existence, as God hath.

It may be Objected, That some Philosophers and Divines hold, that the Duration of the Mind of Man is Permanent, and as they express it, All at once, and ye none of them attribute Eternity to it: So that accordingly, tho' the Existence of God have no Parts whereof some are before the other; yet for all that Duration may be attributed to him.

VII. An Answer to this Doubt.

I answer, That Permanent Duration can only improperly be attributed to the Mind of Man, because we find a manifest Succession in our Thoughts, whereof nothing is to be found in the Divine Perception. But to explain my Mind more fully, I think that Permanency is very improperly attributed to Creatures, forasmuch as the most Perfect of them, cannot all at once admit all the Attributes and Modes it is capable of. For as it implies a Contradiction for a Body at one and the same time to admit several Figures, as to be Square and Round, to Move and Rest, so neither can a Created Spirit affirm and deny the same thing, or comprehend all those things with one Thought, which it is capable of knowing. But GOD posseth all Perfections, and all Attributes, at one and the same time, neither is any of them before or after the other. And therefore Permanence appertains only to GOD, and Duration to all other Beings. Besides, since all Creatures are Created by God with equal dependency, and have their Preservation no longer than he pleaseth to continue it; it follows, that their Duration is not permanent, but successive, and can indeed be nothing else but a continual Reproduction, by which they persevere in their Beings.

CHAP. IX.

That GOD is Infinite, and how we are to understand, that he is Circumscrib'd in no Place.

I. All things are not contain'd in some place.

Amongst those Prejudices, which we have taken in from our Childhood, and which come to this day hold for Truth, there is none more dangerous in Philosophy than that which ARISTOTLE teacheth in the Fourth Book of his Natural Philosophy, the First Chapter, viz. That all things are somewhere, that is, contained in some certain Space; because he supposed whatsoever is not to be no where; which he takes to be so notorious and evident, that he is not afraid to rank it amongst Common Notions, and to esteem it an indubitable Truth. Wherefore also in his First Book of Heaven, the Third Chapter, he assigns the Highest place to the Gods, as most becoming their

Dignity, and whence with greater ease they may take a View of all Things. And in the same Book, Chap. 2. he disputes against the most ancient Philosophers, and denies God to be diffus'd through all Things, as supposing it most unworthy the Divine Majesty to be present with the Earthly World.

But that this is an Erroneous Opinion, appears from the Immensty of GOD, and the Existence Immaterial of Spiritual Things: For it is evident that God and Immaterial Substances are, or have a Being, and yet they are not comprehended in any determinate Place. For to be in a Place is the Property of Extended Beings, and cannot be attributed to an Immaterial Substance void of all Extension. If at any time Places be attributed to the Soul, this is not with respect to its own Essence, which consists only in Cogitation, but with respect to the Body, to which it is joyned; because it cannot be, but that the Body being limited to a certain Space, the Soul, which is intimately present with it, may be said to be included in one place, rather than in another. But if the Soul be considered by it self alone, forasmuch as it is a Thinking Substance and void of all Extension, it cannot fill any Space, nor have any situation amongst Bodies; for otherwise it would be Divisible and Mensurable, which is repugnant to the Nature of an Intellectual Being.

And as for GOD, he is much less comprehended in any Place: For tho' he be said to be every where, yet may he also be said to be no where; forasmuch as his Immensty is unbounded and diffus'd through all Places. But because all do acknowledge, that the most Perfect Being hath no Bounds, either of his Duration or his Presence, the only difficulty will be in the Explication of the Divine Immensty, viz. in what sense God is said to be Infinite, and so diffus'd through all, as to be every where.

Some, whom I call Vulgar Philosophers, derive the Immensty of God, from his Presence in every place, supposing God to be every where, because there is no place in which he is not present, or which is not filled by him. But these seem to Attribute Extension to God, by conceiving to partake of Quantity, as Occupying all places: And therefore would think his Greatness to be Finite, if there could be any place, in which he were not present, and coextended with it.

Whereas we know that God was, before there was any Space; for what Place did God fill before the Creation of the World? If God therefore did Exist before there was any Space, it is evident that being in a Space is not Essential or Proper to him.

Wherefore to leave this gross way of Philosophizing, we say, that God is precisely Infinite, forasmuch as all Created things, are every moment as it were anew Created, and cannot Exist without his continual Influx: For the perpetual dependence of the Creatures, doth clearly Evidence Gods Omnipresence; because those things, which are in Nature, are not preserved by any Force or Virtue of their own, but only by the Essence of God, and by his Favour continue in their Beings. Neither is a less potent Cause required to the Preserving of things, than was to the Creation of them. For from this that a thing now Exists, it doth not follow, that

III. God is comprehended in no Place.

IV. Some falsely suppose God to be every where by his Presence.

V. God, before the Creation of the World, was not in any Space.

VI. God is said to be every where, because all Created things perpetually depend upon him.

it shall *Exist* the next moment, since there is no necessary Connexion of the Parts of time, but one of them is alway distinct from the other; so that *God* must influence his *Creatures* in the same manner for their Conservation: In which Conservation, and presence in every thing, the *Immensity* of *God* doth consist. Thus *God* is said to be present to our *Minds*, because he is with every one of our *Thoughts*, and concurs to every determination of our *Wills*. And he is said to be present to our *Bodies*, because he doth dispose, move and make them rest. Lastly, he is present to all other things, because he doth as it were continually produce them anew, cherishing and preserving them by a way that surpasseth our Understanding.

VII.
God is not
present e-
very where
by his Pow-
er, but by
his Essence.

Neither can I assent to those who say, that *God* is present every where, not by his *Essence*, but by his *Power* only, by which they seem to divide his *Power*, from his *Essence* and other *Attributes*; whereas indeed all things that are in *God*, are one with his *Essence*; nor are his *Attributes* any thing else, but divers *Modes* of *Thinking*. For they must be fain to confess that this *Power* is something that is *Created*, or something that is only accidentary to the *Divine Essence*, without which he may be understood or conceived. Now it is the most absurd thing to make it a *Creature*, since whatsoever is *Created* doth stand in need of the *Divine Power* for its *Existence*; and since this *Divine Power* it self is supposed to be a *Creature*, it will stand in need of some other *Power* to preserve it, and by this means we shall make a *Progress* to *Infinity*. Or if they will rather make this *Power* to be accidental to *God*, and distinguish it from his *Essence*, then they must be forced to admit, that *God* is not a most *Simple Substance*; because, according to their saying, he would be compounded of his *Essence* and that *Power*. Wherefore we conclude, that *God* is present to all things by his *Essence*, and that he is in every *Place*, forasmuch as he continually procreates and conserves the things which he hath *Created*.

VIII.
The Im-
mensity of
God is only
an Exter-
nal Deno-
mination.

Hence we may perceive the false way of *Reasoning* used by the *Peripateticks*, who to make out the *Doctrine* of *Gods Immensity*, have invented imaginary *Spaces*; as if the *Immensity* or *Omni-presence* of *God* were any thing else, but an *Extrinsical Denomination*, taken from his *Works*, forasmuch as he *Works* in all *Created things*, and by Reason of that Operation is said to be present with them. For *Immensity* in *God*, seems to have some Affinity with *Creation*; and as *Creation* is Attributed to *God*, from the *Action* of *Creation*, since before the *Creation* he could not be called a *Creator*: So likewise *Immensity* is Attributed to *God*, with respect to his *Creatures*, since he could not be present with them, before they were *Created*.

CHAP. X.

That God is the most Simple Being.

I.
What Com-
position is,
as it is op-
posed to
Simplicity.

AS things are more clearly and distinctly perceived by comparing them by their contraries; so I suppose it will be of great use for the Explaining of the *Simplicity* of *God*, to unfold what *Composition* is, and to what distinction of parts it answers. Now *Composition* is the Coalition or Union of many things, which presupposeth a distinction of *Parts*, since nothing can be united to it self, but

to another. And it is various according to the diversity of the *Parts*, of which things are compounded.

For one *Composition* is *Real*, which consists of *Parts* really distinct; as a *Man* is compounded of *Soul* and *Body*, because we can clearly and distinctly perceive the *Mind* without the *Body*, and the *Body* without the *Mind*. Another is *Modal*, which consists of a *Subject* and *Antecedent* or *Mode*; as a *Prudent Man* is compounded of a *Man* and *Prudence*; and is known by this Mark, that tho' a *Substance* may be clearly perceived without the *Mode*, by which it is diversified; yet on the contrary, the *Mode* cannot be clearly understood without the *Subject*, whose *Mode* it is. The third sort of *Composition* is called, a *Composition* of *Reason*, which consists of the *Genus* and *Difference*, as when *Man* is said to be compounded of an *Animal*, and *Rationality*. Which consists in this that we cannot perceive a thing clearly, if its *Attribute* be excluded from it: As *Extended Matter* or a *Body*, is said to differ only by Reason from *Extension*, because we cannot conceive a *Bodily Substance*, if *Extension* in Length, Breadth and Depth be separated from it. And therefore, such kind of *Attributes* as these are not called the *Modes* of *Things*, but only *Modes* of *Thinking*, forasmuch as by the help of *Reason* only, they are distinguished from those things, with respect to which they are so called.

These things presupposed, it will not be difficult to shew that *God* is no *Compound*, that is, that he hath no *Parts* that are Really or Modally distinct from each other. For there is no more certain *Argument* of a real Distinction, than that the *Idea* of one thing is perceived, not to be the same with the *Idea* of another thing; or to speak in *School Terms*, that the one can *Exist* without the other: But it is manifest, that no such distinction is to be found in *God*, forasmuch as all his *Attributes* are *Essential*, and not *Separable* from him, but by the Operation of our *Mind*.

Moreover the things that go to the making up of any *Compound*, must at least by *Nature* be before the thing *Compounded*, or that is made up of them: Thus every *Cause* is said to be before its *Effect*; *Substance* before *Accidents*; and *Subjects* before *Adjuncts*: And therefore those *Substances*, by the Union of which *God* is supposed to *Exist*, must of necessity have been before him, since we understand them to be before they constitute the *Divine Essence*. Thus *Matter* and *Form*, which are considered in *Natural Philosophy*, as the two *Principles* of a *Natural Compound*, are apprehended to be, before they do constitute their *Compound*. And in like manner, if really distinct *Substances* were found in *God*, they would be intelligible to us, before that they were Attributed to him; yea tho' they should never be Attributed to them.

And forasmuch, as we acknowledge only two general heads of things, viz. *Material* and *Spiritual*, we must of necessity suppose, that the things of which *God* should be composed, must be *Corporal* or *Intellectual*. If the first, it will follow, that seeing a *Body* is the immediate Subject of *Local Motion*, *God* is *Divisible* and *Limited*, yea, Subject to *Passion* and *Alteration*, all which include Imperfection, and consequently are repugnant to the *Divine Nature*. If they be supposed to be *Spiritual*, since there is a real distinction between

tween them; and one of them according to the Rules of Logick, can Exist separate from the other, consequently there will be as many Gods as there are Substances, that are supposed to constitute God. For seeing they can Exist by themselves, and need no assistance from any other to their Conservation, they will also have power to confer upon themselves all the Perfections, which belong to God alone. Than which nothing more absurd can possibly be imagined by the Mind of Man.

VI. We say therefore, that there are no Substantial Parts in God, into which he can be divided, or from the Union and Coalition whereof he doth consist. Neither is there any Composition in God, out of a Subject and Accidents or Modes; because Modes arise only from the various Change of the Substance, which therefore cannot be supposed in God, because in him there is no Change or Variation. Wherefore it follows, that whatsoever is in God, is only distinguishable by our Thoughts, because every Attribute of God may be called his Essence, and have the name of supreme Perfection: And therefore are neither more nor less than the one God, in the Unity of Nature. So that we must conclude God to be the most simple Being, utterly devoid of all Parts, or Divisibility.

CHAP. XI.

God is true, and as he cannot be deceived, so neither can he deceive.

I. **T**HO' Human Cogitation be commonly held to be the Rule of Truth, and whatsoever, we clearly and distinctly perceive, is supposed to be true; yet all this certainty would come to nothing, if God were not true, and most remote from the least suspicion of deceiving us: For how should we believe Revelation, if it were possible for God to deceive us? For he having bestowed upon us our Intellectual Faculties, it might be questioned, whether it was not his pleasure to make us such, as that in the use of them, we should be deceived, and against our will fall into Error.

II. But this Doubt will be easily removed, and the Truth is a necessary Ingredient of a Being absolutely Perfect. Divine Veracity cannot but be manifest, by considering that all Perfections that can be conceived by us, do belong to God. For, so much as he is the Highest Being, he must also of necessity, be the most Sovereign Good and Truth: Now it is as much a Contradiction, that any Falsity should proceed from the Highest Truth, as that any Evil should come from the Highest Good: Which yet would be, if in the use of our Faculty of knowing, that is, in assenting to things that are clearly and distinctly perceived by us, we should fall into Error. And indeed seeing that whatsoever is real in us does proceed from him, and that the Faculty we have for the knowing of Truth, and distinguishing it from Falsehood, is Real, we could not but take him for a Deceiver, in case our Faculty could not reach the Object, but should always take Falsehood for Truth. Than which nothing can be imagined more injurious to the most Perfect Being, and the Fountain of all Good.

III. Besides by the Name God, we understand the most perfect Substance; and Imposture or Deceit is a manifest Imperfection, because it has a non-En-

tity for its End, that is, something that is not true; should deceive us, implies a Contradiction. for all Deceit includes Falsity, which being opposed to Truth, it must be carried to that which is no Truth, that is, a non-Entity: So that from hence it will follow, that God cannot without a contradiction be said to deceive us.

IV. Lastly, Tho' perhaps amongst Men, it may be accounted a piece of Cunning to deceive others, yet Falseness or a will to deceive others, proceeds from Fear or Malice: And so much as Fear supposeth Weakness, and Malice the want of Goodness, neither of these can be admitted in God; and consequently neither can a Will to deceive be ascribed to him; yea, he must be supposed to be the Highest Truth, and not thought a Deceiver upon any account whatsoever.

V. You will object that he who concurs to those Actions of the Will, or those Judgments by which a Man is deceived, he is to be looked upon as the Cause of that Man's Error: But God so concurs to those Judgments of Men, by which they are deceived; therefore God is the cause of Men's Errors.

VI. This Objection is easily answered by distinguishing between the Material and Formal, or between an Act and its Privation. For all Acts are true and Good, so much as they depend on God; and as it is a greater Perfection in Man, that he can exert them, than if he could not. But Privation, wherein alone the Formal Reason of Falsity doth consist, doth not stand in need of any Divine Concurrence, because it is Nothing, and with Relation to God, is not to be call'd a Privation, but only a Negation.

VII. I know that some Divines seem of a different Opinion, who think that God can deceive Men, by inspiring them with Ideas that deceive them; and that he does this of his free Will, as being the Supreme Lord of all, and therefore may deal with his Creatures, as he listeth. So as that they are clearly persuaded that they feel something, which indeed they do not, according as it happens to the Devils and Damned Souls, who think they are tormented with Fire in Hell, when indeed there is no Fire there at all; or if there be any, it is Material, and so cannot affect Pure Minds.

VIII. I Answer, That GOD does not deceive, or by false Apparitions delude the Devils or Damned Souls; because the Fire wherewith they are tormented, is not only an Idea of Fire impress'd on them by God, but the true substance of Fire wherewith they are tormented, and sensibly affected. For why may we not suppose, that God can joyn the Soul of Man with some Body, and so unite his Thoughts to the Motions of that Body, that according to the greater or lesser force of the one, a greater or lesser sense of Pain may be excited in the other? For as we see that the Soul of Man is kept link'd to the Body, so it may as well, by the Divine Power, be detained and suffer by Corporeal Fire (as we suppose that in Hell to be) seeing that this is consonant with the Scripture, and establisheth the Truth of GOD.

IX. If any one urge further, That GOD doth sometimes harden the Hearts of Sinners, and so blind their Minds, that they condemn his Commands, and run headlong into the greatest Sins, as appears by PHARAOH, whose Mind the LORD did so incline to Evil, that it was not in his

his Power to obey his *Precepts*. Besides, we read in *Scripture*, That GOD put the *Prophets* upon foretelling Things that did not come to pass; as appears from the History of *Jonah* the *Prophet*, who declar'd from God to the *Ninevites*, that their City should be destroyed within forty days, which never came to pass.

X. Answer. I Answer, That tho' *Pharaoh*, by the Perverseness of his Will did refuse to obey God, and to dismiss the *Children of Israel*; notwithstanding the frequent Warnings he had had from above; yet is not this so to be understood, as if God by any positive Influx had hardened his *Heart*, and forced him to despise his *Commands*; but only that he withheld *Efficacious Grace* from him, and left him to his own wicked Will. And as for *Jonah*, who foretold the ruin of the City *Nineveh*, that is not to be called a Lye, but rather a Threatning or Denunciation, the Execution whereof depended on their Obstinacy or Conversion, as appear'd by the Event: For the *Ninevites* Repenting in *Sackcloth* and *Ashes*, and earnestly deprecating the *Divine Displeasure*, did escape the *Prophet's* Commination.

XI. God may sometimes deceive us for our Good. Tho' it be a most undoubted Truth, that it is repugnant to the *Divine Perfections* to deceive any one; yet this does not hinder, but he may make use sometimes of a Prudent Deception towards us for our profit, in like manner as *Physicians* and *Parents* sometimes deceive their *Patients* and *Children* for their good and advantage. Neither can God properly be said to deceive us, when things appear to us otherwise than they are; because God is not the cause of that Deception, but we ourselves, who judge of *Bodily things* according to their *External appearance* before that we have sufficiently examin'd them; forasmuch as in these and the like Appearances we should suspend our Judgment, before we do determine any thing concerning their Truth.

XII. We cannot be said to be deceived, when we imagine the Sun to move, and the Earth to stand still. Thus GOD cannot be said to deceive us, when by the *Earth's* whirling about its *Axis*, the *Sun* seems to us to rise and set; but we rather deceive our selves, when we attribute *Motion* to the *Sun*, and *Rest* to the *Earth*, before we have fully discuss'd the Point: When indeed we ought to suspend our Judgment until having weigh'd the Reasons on both sides, we did clearly and distinctly perceive, to which of these *Bodies* the motion we perceive were to be ascribed. Neither are the *Common People* look'd upon to be absolutely in an Error, when they suppose the *Sun* to move every day about the *Earth*, tho' it be not true, because herein they follow what seems probable, which is sufficient to free them from the imputation of being deceived.

XIII. From God's Veracity we may conclude, that whatsoever is clearly perceived by us, is true. Hence it follows, that whatsoever is clearly and distinctly known by us, is true: For since the Light of *Nature*, or our Faculty of *Knowing*, hath been given us by God, it can reach no *Object* which is not true, so far as it is reached by it; that is, forasmuch as it is clearly and distinctly perceived. For God might with reason be look'd upon as a Deceiver, in case he had given us a Faculty that embraced Error instead of Truth: Wherefore forasmuch as *Mathematical Truths* are most clear and evident, so as to thrust themselves upon our Understandings, we ought not in the least to suspect them, but receive them as undoubted Truths.

CHAP. XII.

That GOD is most highly Intelligent, or Omniscient.

IT will not be any hard matter to make out, that GOD is Omniscient or All-knowing, and that at one view he comprehends all things, if we remember him to be the Most perfect Being, in whom no defect or limitation can be conceived, which would not be if his Knowledge were finite, and that any thing could escape his Understanding. Therefore the *Ancients* called GOD, the *Mind*, or *Soul of the World*; not only for that he was diffused throughout the Universe, and did animate all Things; but also because he knows them all, and pierceth their most Secret parts. For Ignorance is a mark of Weakness of Soul, and that Being cannot but be Imperfect, whose Understanding is bounded by any Bound or Limit, beyond which it cannot reach.

But because Discourse and Reason serve to illustrate the Truth of Things, I shall make use of this Argument: Either GOD understands all things, or some things only, or nothing at all. If he only understand some things, then his Understanding is supposed imperfect, which no body will say of God, that is persuaded of his absolute Perfection. But if he knows nothing, then certainly he cannot be supposed to be God. Wherefore it follows, that as God contains all Perfections, so he is endowed with knowledge in the highest and most transcendent degree.

I say, in the most transcendent degree, because Human Cogitation is very different from the Divine. For the *Idea's* of Men are bounded by the *Objects* that are without them, and according to the diversity of things which it contemplates, are said to be either clear or obscure. For it does not depend of us, that our *Idea's* do represent this or the other thing to us, they being only *Modes* of Cogitation, and as such are all of them equal, all their difference proceeding from the *Objects* they represent; so that some hold forth to us an Extended Substance, others a Mind; some Simple things, others Compound; all which variety the *Idea's* borrow from the Things themselves. For it cannot be question'd, but that those *Idea's* which represent some particular Substance to us, contain more objective Reality, than those which only exhibit *Modes* to us, which are only the determinations or limitations of Substance. But the Divine Knowledge doth not thus depend on the *Creatures*, neither are his Conceptions bounded by any things without him; but all Created Beings derive their Essence from his Understanding, and according as they are determin'd by the same, do obtain divers degrees of Entity. For the Divine Intellect; whereby God knows the *Creatures*, is the same thing with his Will and Power that does determine them, and are only distinguish'd by us, according to our various ways of considering them.

Wherefore we are not to suppose any *Object* of the Divine Science to be without himself, who is alone the *Object* of his own Knowledge; or to speak more properly, He is himself his own Knowledge. For should we suppose, that Created Beings were before the Divine Intellect, and that as *Objects* they did terminate his *Idea's*, they must be supposed to have a Nature and Essence independent

on God, as being at least by Nature before him. Which to assert would be as foolish, as to say that a *Pourtraiture* drawn by a Skillful *Limner*, is the *Object* of that Art: For a *Limner* stands in need of *Pencils* and *Colours*, to perform his *Work*; whereas GOD did not stand in need of any thing for the *Creation* of the *World*, but all *Created things* did proceed from his *Understanding* and *Free Will*; not only as to their *Existence*, but as to their *Essence* also.

V. Whence it appears, that *Indifferency* which is an Imperfection in Man, and is held to be the lowest degree of his *Liberty*, is the *Highest Perfection* in God, as being a sign of his *Sovereign Empire* and *Power*, who is unbounded by any *Laws* or *Rules*, and the sole *Author* of all *Order*, *Truth*, *Justice* and *Goodness*. For it implies a *Contradiction*, to suppose that the *Divine Will* was not indifferent to all things, that have been or shall be made. Because no *Goodness* or *Truth* can be imagined, the *Idea* whereof was in the *Divine Intellect*, before that his *Will* had determined to make it so.

VI. Some Question whether the *Divine Knowledge* doth extend it self to all things, and whether God besides *Positive things*, that is, real *Substances*, doth also know things *Privative* and *Fictitious*, such as are *Sins*, *entities of Reason*, &c.

For Answer I say, that God knoweth all things whereof he is the *Efficient Cause*, because as was said in the Chapter of Gods *Immensity*, all things are continually procreated by him, as not being able to continue one Moment without his *Concourse*: But *Sins* being no real things, and depending on the *Will* of Man, are not known by him without the *Minds* of Men. And as for *Entities of Reason*, forasmuch as they are nothing else but *Modes of Thinking*, which are used for the easier *Explication* of the things we know, or the better retaining of them; these are no otherwise understood by God, than as he is the *Procreator* and *Conservator* of our *Minds*. For if we enquired what is meant by an *Entity of Reason*, we shall find it to be a *meer Nothing*, without the *Understanding*. But if we have regard to the *Modes* themselves of *Thinking*, they may be said to be real *Entities*. Thus, when I enquire what is *Genus*, I demand nothing else but the *Nature* of that *Mode of Thinking*, which is truly considered as a *Being*, and differs from a *Species*, which is another *Mode of Cogitation*.

VIII. Now God doth not contain any of these *Entities of Reason* or *Notions*, as if he stood in need of these *Modes of Cogitation*, to retain the things that he understands; but only inasmuch as the *Mind* of Man, whose *Modes* they are, is perceived by us to be preserved and maintained in its *Being* by God. We conclude therefore that God is *All knowing*, and that he contemplates all things by one only most *Simple Idea*; for to speak properly, God for no other Reason is called *Omniscient*, but because he has his own *Idea*, which being nothing else but his *Essence*, is therefore inseparable from him, and consequently extends it self to all positive or real *Objects*.

CHAP. XIII.

That God is Good, and doth Good.

I. Seeing that no *Creature* exists by its own *Power*, and that all thing derive their *Essence* from God,

we must conclude that God is Good and Beneficent. is said to be Good. For as by his comprehending all things he is *All-knowing*, and by his Power to do all things, *Omnipotent*: So because he hath *Created* all things, he is said to be Good, and because he preserves the same, *Beneficent*.

II. This will more clearly appear, if we consider what Good and Evil is, and wherein precisely the Nature of both doth consist. A thing considered by it self apart, cannot be said to be Good or Evil, but is denominated such with respect to an other thing, to which it is profitable or hurtful. And accordingly, the same thing may at the same time, be said to be both Good and Evil. So the Punishment inflicted on a Criminal is Good, forasmuch as it conduceth to the Safety of the Commonwealth, and to deter others from committing the like Crimes: And yet it is Evil to the Criminal, because by the same he suffers Death, which deprives him of Life, being the dearest thing he enjoys. So likewise the Sea is of great use for the carrying of Ships, and in that regard is a Good to the Merchants; but Evil when raging by a Storm it Swallows and Shipwracks their Vessels. Yea, there be many Good things, which are not such to all: Thus, to be in Heaven and to enjoy the company of the Blessed, is a Good, yea the greatest Happiness to Man, but yet to Brutes and Plants it is neither Good nor Evil, as having no Relation to them.

III. GOD therefore is said to be supremely Good, because he does Good to all, and is the Conservator of all things, for all things are preserved by his Omnipotence. Moreover, forasmuch as there is no Connexion between the parts of Durations; and it doth not follow, that because the Creatures exist to day, they will continue to morrow: We may say that Gods Conservation of his Creatures, is a continual production of them. Neither doth it oppose this Truth, that the Will of Man is free, and is oft determined by things without it: Because even those very Actions are determined by God, and are not exerted but by his Good-will, as will be said more at large in the following Chapter. For it implies a contradiction, that any thing should determine the Will, and that the Will it self should not be determined by God, to whom all created things are Subject.

IV. Gods Beneficence doth not only appear in the Creation of the World, and the preserving of all Creatures; but he hath also from Eternity testified his Love unto us, by electing us from before the Foundation of World, and by loving us with an everlasting Love. For as Heat cannot but warm, and Light illuminate, so the highest Love cannot but in the highest degree love it self, and all things proceeding from him. And this Eternal Love of God is manifested by a two-fold effect, viz. the Mortal Life we Live here, and the Immortal Life we hope for, hereafter. With reference to the present Life, he hath adorned the Heaven with Stars, that they might assist inferior things with their Light, and promote the innumerable Generations of Natural things; he hath distinguished the Elements, in their proper Place, endowed them with Qualities, and made them by their inborn Virtues, to concur to the Mixtion and Production of all things; he hath appointed the Fire for Action, the Air for Respiration, the Water and Earth for Fruitfulness, and the Production of so many kinds of things for necessity and delight, but the chiefest Pledge of Gods Love

Love towards us; is, that he hath predestinated us to the Adoption of *Children in Christ Jesus*, so as that we have *Redemption by his Blood*, and the *P forgiveness of Sins*, according to the *Riches of his Grace*. For *Grace hath preceded Merit*; neither doth *Grace come from Merit*, but *Merit from Grace*. He gave for *Nothing*, or out of *meer Grace*, who found *Nothing why he should Save*, and *Much why he should Damn*: He prevented us by the *Blessings of his Sweetness*; for that *Grace tastes sweeter*, which helps even those that have *ill-deserved*, and entertains *Thoughts of Peace towards us*, whilst we do the *Works of Death*. *S. Austin, Sermon 15. de verb. Apost.*

VI. But you will say, What shall not GOD be good then, except he do Good to Mankind, and preserve the Universe? What can be imagin'd more absurd, than not to acknowledge GOD Good, as well as Immense, Wise, and Powerful?

Notwithstanding this Objection, we must assert, That the Attribute of Goodness did not belong to God before the Creation of the World; because a Thing considered in it self, and without respect to others, cannot be said to be either Good or Evil: Neither needs this seem strange or absurd to any one, forasmuch as the Goodness we speak of here, denotes a Respect between God and his Creatures, as his Immensity does, which consists, as we have seen, in that Operation whereby he continues them in Being. So that as supposing they were not, tho' he would be present to Himself; yet Ubiquity, or Omnipresence could not be attributable to him; so before the Creation of the World, tho' GOD be Good by his own Essence, yet because there was nothing on which he could exercise his Beneficence, he was only Potentially Good, Merciful, a Judge, a Creator, &c.

VII. But some will say, If GOD be Good, why doth he permit the Corruption of Nature, and the Sins of Men to offend his Divine Majesty?

To which I Answer, First, That it is not repugnant to the Divine Goodness that there are Sins, and that Men swerve from their Duty; yea, it seems more to comport with his Omnipotent Goodness to bring Good out of Evil, than not to suffer Evil. But yet it is not our business to enquire over-curiously, why God permits Sin, lest we should seem to endeavour with the scanty Line of our Reason, to fathom the depth of the Divine Wisdom.

IX. In the Second place I Answer, That it is not contrary to the Divine Goodness, that he hath not made his Creatures so perfect, as to place them out of the reach of Error, or danger of Falling; and that he hath pitch'd upon such an Order, in which Sins take place; forasmuch as Man Sins without any force put upon him; neither can the Guilt of it be imputed to God: For God did not from Eternity decree Sin, neither did he decree, that Sin should be possible; for seeing Sin is no positive thing, but a deficiency of Reality, it cannot be of God, but he only hath established that Order, in which he sees the possibility of Sin before his Decree and Will concerning it. And therefore upon this Hypothesis only it follows, that having established such an Order, and making positive Things possible, he can be said the Author of Sin; forasmuch as by the said Order, Sin is made Possible, which in this sense is not repugnant to the Goodness and Holiness of GOD.

CHAP. XIV.

Of the Omnipotence of GOD.

NO Man that ever own'd a GOD, deny'd him to be Omnipotent: This is a Notion all Men brought into the World with them, who therefore when they are in any affliction or danger, lift up their Hands to Heaven, and send up their Prayers to him for the thing they wish for, and thereby tacitly acknowledge his Omnipotence. Yet there are some Philosophers who seem to destroy this Notion, who assert the Essences of Things to be Eternal, as if without the Power of God they had some Nature of their own, to which God at a certain time did vouchsafe Existence, and made them to be Actual Beings. And therefore they say, that Possible things only, that is, such as are so in their own Nature, can be produc'd by God, and that his Power doth not extend it self any further.

But because this Doctrine seems to derogate from God's Omnipotence, we will endeavour to shew the Falsity of it, by declaring what the true Nature of a Possible, Necessary, and Contingent Being is, and whence they take these Affections. A Necessary Being is said to be such with a twofold respect, either with respect to its Essence, or to the Effective Principle whence it proceeds. After the first manner, we know that God only doth necessarily Exist; and therefore he is said to Exist so, as that he cannot but exist; because Existence is involved in his Conception, so that his Essence cannot be understood without it. But after the Second manner, that is, with respect to the Effective Principle, Corporeal things are said to be Necessary, forasmuch as they can be produced by God; but not with respect to their own Essence, because we can clearly and distinctly understand the same without Existence, and therefore they can never exist by virtue of their Essence. That is call'd a Possible Being, whose Efficient Cause is known to us; but yet we do not know, whether he be determined to produce it or no; and therefore is commonly described, That which hath not been, but might have been; and in this sense all things besides God are said to be Possible. But if we consider only their Nature, and not their Productive Cause, we shall call all things Contingent; because with respect to their Natures, no necessity of Existing is found in them, as in God: Neither is there in them any Repugnancy or Impossibility, but that they may be; and therefore in case they do exist, they exist so, as that they may not exist.

We will now shew, That all things that are now, or are to come, have their Dependence on God; and that there is nothing in Nature, that doth not proceed from his Decree. For seeing no Creature exists by the necessity of its Essence, it follows, that they must all borrow their Being from the Divine Decree. For it is evident by the Light of Reason, that it is impossible a thing should exist, which hath no Internal or External Cause of its Existence: Now no Creatures can exist by the Power of their own Nature, and therefore we must have recourse to one only External Cause, viz. the Divine Decree, for their Existence; in which Divine Decree, if their Existence be not found, they are to be look'd upon as Impossible, forasmuch as they cannot be produc'd by any Cause. From whence

I. It is an inborn Notion with all Men, that God is Omnipotent.

II. What a Possible, Necessary and Contingent Being is.

IV. All things present, and things to come, depend on God.

III. All things present, and things to come, depend on God.

IV. All things present, and things to come, depend on God.

whence it evidently follows, not only that the Existence of all Creatures doth depend of God, but also their Nature and Essence: for seeing there is no perfection which is not in God; there can be no Essence in the Creatures, which should be the cause of Gods knowledge. Wherefore we must conclude that all Creatures before Gods Decree were nothing, and consequently that of themselves they have no necessity to exist.

IV. When I say that all things have their Being from the Divine Good Pleasure, this to be understood not only of Material Substance, but also of Thinking or Spiritual; because not only the properties and Modes of Bodies derive their reality from the Will of God; but also the Modes of Minds. For it is a meer prejudice of our Youth to imagine that the Modes of Cogitation, Knowledge, Judgment, Affections, and other inward Acts of our Mind do less depend on the Divine Power, than the Modes of Material and Bodily things. Because whatsoever is not God, is of it self altogether nothing; neither can it exist but by his will; for since nothing can be the cause of its own Existence, save God alone, it follows that whatsoever exists, must derive all its reality from God as its first Principle.

V. If it be objected that the Essences of things are commonly said to be Immutable and Eternal. I answer, that the Essences of things are only said to be immutable, forasmuch as they are exprest by Definition, and are consider'd Universally, as is commonly done in Sciences, whose certainty requires firm and stable Definitions. So the Definition of a Mind that it is a Thinking substance, is always the same, neither is lyable to any change, tho perhaps there may be a further degree of perfection in the Mind of one Man, than of another. And whereas they are said to be Eternal, or that their Essence was known from Eternity in the Divine Intellect, this does not argue any Eternity in them, but in God; since to be known in the Mind of God, with respect to the Creatures, is only an Extrinsecal Denomination, or an Entity of Reason, which superadds no reality to things.

VI. As for Possible and Contingent Things, there are none such with respect to God; Because there are none that of themselves can Exist, and not Exist, or that have real Contingency. For surely there is no less Power to the creating of a thing, than to the Conserving of it; and since no created thing acts any thing by its own Power, so neither can it give it self Existence by the same. It remains therefore that all things must have their Dependence on God, and that the things that are, be produced by vertue only of the Divine Decree. And forasmuch as there is no Change or Inconstancy in God, we must conclude that the things which he creates, have from Eternity been decreed to be created by him; so that all Creatures from Eternity had a kind of necessity of Existence; And therefore that no Things are Possible, Necessary, or Contingent of their own Nature, but by the Divine Decree, which is the only Cause of all things.

VII. Neither doth it contradict what we have said, that God might have decreed otherwise concerning his Creatures, and that upon that score they may be said to be contingent; For since in Eternity there is no Before or After, first or last, it is a Vanity to search after those Moments in which God existed

before those Decrees, and in which it is supposed that he might have determin'd otherwise. Wherefore since God without any necessity resolved to make Creatures, they are all of them said to exist Contingently, because they include no Necessity of Existing; tho with respect to the will of God they exist Necessarily: Forasmuch as no greater necessity can be conceived in Things than that whereby an Effect follows from an Efficacious Principle and a Determinate Efficient Cause.

There is one difficulty more remains to be discuss'd, and that is since all Creatures are predetermined by God, and that there is a kind of necessity of Existence in them from Eternity, how the Will of Man can be said to depend of God, seeing that it is free, and indetermin'd. But notwithstanding this, we must say that the Will also is conserved by the Divine Concourse, so that it is not in the Power of Man to Will or Act any thing, which is not preordained by God. But how these two things may be reconciled, that God hath decreed all the Acts of our Will from Eternity, and yet our Will remains undetermin'd, is I confess more than I do clearly perceive. I do acknowledg my Mind to be but of a finite capacity; and the Power of God, whereby he hath not only foreknown all present and future things from Eternity, but hath also decreed and determin'd them, to be infinite and unbounded: Yet cannot this consideration make us doubtful of the Freedom of our Will, since in all our actions we experience our selves to be free, and that it is in our Power to give or withhold our Assent; which is so manifest that we have good reason to rank it amongst first and common Notions.

Hence is it that the Famous Philosopher in the Ninth Epistle of his 1. Volume, saith. As to Free will, if we only consider our selves, I must confess we cannot but think it to be Independent: But when we cast an Eye on the Infinite Power of God, we cannot but believe that all things must depend on him, and therefore that our free will is not exempt from his Command. For it implies a contradiction that God should have created Men of such a nature, that the Actions of their will should not depend on his will: Because that is the same as if one should say that his Power is both Finite and Infinite: Finite since there is something that doth not depend on it; and Infinite, in that he was able to create this thing Independent. But as the knowledge of the Divine Existence, must not take away the certainty of our free will: So neither must the knowledge of our free will, make us to doubt of the Divine Existence. For the Independency we experience and find in our selves, and which makes our actions blame or praise worthy, is not opposite to a dependence of another kind, whereby all things are subject to God.

Gods Omnipotence does not only appear in the Production of things, but also in their conservati- on: for God is not only the Principle of created Beings when they are making, but also when they are made. Hence it is that he preserves them by a continual Influence; and should he cease from his Concourse, whatsoever he hath produc'd would fall to nothing; Because before they were created and he afforded them his Concourse, they were nothing. Neither doth it contradict this, that all things that are produced by God are substances, to whom

VIII. How the Will of Man is said to depend on God.

IX. It is a difficult thing to reconcile the Divine Liberty of Mans Will.

X. God is no cause of the Creature when it is made than when it is made making.

I. Some Attributes agree to God from Eternity, others in Time.

II. Whatsoever hath a Being, hath its either from itself, or from another.

III. Forasmuch as the Parts of Time have no necessity of connection, it follows that Creatures are not preserved by themselves.

IV. The Essence of things are clearly known by abstracting them from Existence.

whom it does agree to subsist; for they are not call'd *Substances* as if they could subsist without the *Divine Concourse*, but because they are such things, as do not need the assistance of any *creature* towards their being. In which Preservation of the *creatures*, the infinite *Divine Power* is evidently exemplified, in that he hath produc'd all things so, as that they cannot subsist one moment without him, like as the Image of the *Sun* reflected in the *Water*, or in a *Looking-glass*, doth depend on the *Sun*, not only as to its being, but as to its Preservation or continuance.

CHAP. XV.

That God is the Creator of all things.

I. Some Attributes agree to God from Eternity, others in Time.

THO all the *Divine Attributes* be Eternal, and undistinguish'd from his *Essence*, yet do not all of them in a like manner agree to him. For some of them constitute his *Nature*, and can only by the operation of our *Minds* be separated from it, such as are his *Eternity*, *Omniscience*, &c. Others again presuppose *creatures*, and are only attributable to him since the beginning of the *World*, as to be a *Judge*, a *Creator*, &c. Which from *Eternity* did only Potentially belong to him. But because the *Power* to create the *World* was in *God* from *Eternity*, and that it appertains to his *Nature* to be *Omnipotent*, it is as easy to prove *God* to be the *Creator* of all things, as it is to evince him to be *Immutable*.

II. Whatsoever hath a Being, hath it either from it self, or from another.

For whatsoever is besides *God*, either hath the Principle of its *Existence* from it self, or from another: For natural light evinceth that things can not be made of nothing. If any thing was of it self, it would want nothing; Yea, it would give it self all those Perfections it hath any *Idea* of; but nothing hath the *Power* of bestowing those perfections on it self, for otherwise it would actually be possessor of them; for the *Will* is infallibly carried to the Good it knows; and consequently it hath not the *Power* of giving it self a *Being*. If it hath its *Being* from another, we may then demand whence that other hath his *Being*, whether from it self or from another, till we come to the last *Cause*, who is the *Author* of all things that *Exist*.

III. Forasmuch as the Parts of Time have no necessary connexion, it follows that Creatures are not preserved by themselves.

Besides, the *Parts of time* have no necessary dependence on each other; neither doth it follow that because a *thing* is now, it will be the next Moment: Therefore to the end it may continue to exist, there must be some *Power*, which may each Moment reproduce it: But no such *Power* is in the *Creature*, and therefore there must be some *Being*, whose *Nature* includes *Existence*, and which is the *Cause* why the thing that hath existed hitherto, doth continue so to do. For tho' a thing have begun to *Exist*, yet doth not its *Essence* any more involve necessary *Existence*, than it did before its *Existence*; and therefore it stands in need of the same *Virtue* to continue to exist, as it had to begin to exist.

IV. The Essences of things are clearly known by abstracting them from Existence.

Moreover we clearly understand, that the *Soul of Man* is a *Thinking Substance*; that a *Body* consists of three Dimensions, and that *Man* is a compound of *Mind* and *Body*, without any *Existence*: Wherefore we ought not to ascribe to *Man* any *Power* whereby he can exist, and therefore he must be created by *God*, before he can exist. For every Effect we know is contained in its Cause, either formally or eminently, and seeing neither the *Soul*

nor the *Body*, nor *Man* that consists of both, can be the *Causes* of themselves, they cannot be contain'd in themselves as in their *Cause*; and therefore we must look out for a higher *Cause* that may eminently contain whatsoever is formally found in the *Creatures*; and that is that which we call *God*.

And forasmuch as the *Form*, according to *ARISTOTLE* gives *Being* to a thing, and *Concretes* are more perspicuously understood by their *Abstracts*; for a Confirmation of what we have said, it will be worth our enquiry what *Creation* is, and whether the name of *Creator* could be attributable to *God* from *Eternity*.

As to the first, the received Definition of *Creation* is, that it is the Production of a thing out of Nothing; Which may be admitted without Hesitation, if by *Nothing* we understand a Negation of all Reality, and not any thing Imaginary, which some do suppose to be that out of which all things are produc'd. For some do conceive this *Nothing* to be, as it were, a matter shut up in an Imaginary space, from whence all things do proceed. Wherefore, lest I should seem to favour their Error, I will take away all Ambiguity and define it thus, viz. That it is an operation, whereby things are produc'd by an efficient Cause, no other Cause concurring with it. So that a thing is said to be created, which besides *God* needs no other Cause towards its *Existence*. Where it appears that neither *Modes* nor *Accidents* are created, since they depend on the *Substance*, in which they are, and without which they cannot be conceived: As we have shewed in our *Logick*, in the Chapter of *Substance*.

A thing Created is that whose nature or *Essence* can clearly be understood without *Existence*. As the *Soul of Man*, of which we have a clear and distinct Notion, for as much as it is a *Thinking Substance*, abstracted from its *Existence*. And likewise we have a distinct conception of a *Corporeal Substance*, as including three Dimensions, without considering its *Existence*: And therefore these must be Created by *God* before they can exist, and when they do so, must be preserved by his continual *Influx*.

It remains now to enquire whether *God*, could be call'd a *Creator* from *Eternity*, or whether the things created by him could have their *Original* before all Time. Before we can resolve this clearly, we are to take notice that before the *Creation* of the *World*, no *Time* can be understood by us, seeing that *Time* is nothing else but the measure of *Duration*; or to speak more clearly, is nothing else but a meer Mode of *Thinking*. For as the *Modes* of *Material things* serve for the easier explication of their *Natures*, so we make use of *Time* to express *Duration*, so that it is necessary that before *Time* could be, there must have been, not only *Creatures*, but *Men* also, that might compare the *Duration* of things *Existing*, with the *Duration* of other things, that had a determinate *Motion*. Now *Duration*, seeing it is not distinct from the *Existence* of things, save only by Reason, begins as soon as they began to exist, and ceaseth when they cease to be; because it supposeth them to be Created. Wherefore they who imagine *Duration* or *Time* before the first Production of things, are as deeply prejudic'd as those are who fancy an *Extension*

V. Abstracti- ons do more clearly explain the nature of a thing.

VI. What Creation is.

VII. What we are to understand by the Name Creature.

VIII. Before the Creation of the World, there was no Time.

tion of *Space*, without any Bodily Extension. To enquire therefore, whether a *Created thing* could be from *Eternity*, is as much as to demand whether there can be a *Duration* without any *Beginning*, and which cannot be expressed by any Number whatsoever.

IX.
God cannot
produce E-
ternal Du-
ration.

That such a *Duration* as this cannot be created by *God*, appears from hence, that no *Duration* can be mentioned, but that *God* is still able to produce a greater. For such is the *Nature* of *Duration*, that assign what *Duration* you please, a greater or lesser can still be conceived, seeing that it is, as it were composed of *Parts*, and always may be conceived as *Divisible* into them: For as there are no *parts* in a *Body*, altogether *Indivisible*; so neither are there any *Moments* in *Duration*, but may still be divided into lesser parts to *Infinity*.

X.
No Dura-
tion can be
understood
to be in
God.

Neither can we say, that because *God* hath been from *Eternity*, and is still, therefore we ought to attribute to him the greatest *Duration* that can possibly be conceived; for it is evident from what hath been already said, that no *Duration* consisting of *Parts* can be ascribed to *God*, but *Eternity* only, which is not an affection of *Existence*, but of *Essence*: And therefore that we cannot conceive any *Duration* in *God*, except we have a mind to destroy the *Idea* we have of him; forasmuch as it is essential to the notion of *Duration* that none can be conceived so great, but still greater may, which in no wise can be attributed to *God*, who is *Infinite*, and admits no *Division* of *Parts*.

XI.
Whether
God could
have Cre-
ated the
World from
Eternity.

You will say that *God* is as *Powerful*, whilst he acts freely, as if he did act necessarily, since liberty or necessity of acting, doth not alter the property of *Power*. But if *God* acts by necessity of *Nature*, he must have *Created* the *World* from *Eternity*, forasmuch as his *Power* is *Infinite*, and consequently it is no contradiction, that a *Creature* should be *Eternal*, that is, be produced without a *Beginning* of *Duration*.

XII.
Answer.

I Answer, that this *Argument* is deduced from a false *Hypothesis*, viz. that if *God* should act necessarily, he might for all that be of *Infinite Power*, which is very false; because it is the Property of a most perfect *Being* to act freely, which is so essential to it, that it can never be separated from its *Idea*: since there is but one only *Being*, that by us is conceived to be such.

XIII.
God can
produce still
greater and
greater Du-
ration.

Besides, it is the *Nature* of *Duration* that how great soever any is supposed, it may be still supposed greater; and therefore *God* who is of *Infinite Power* and a free *Agent*, may always produce a greater or lesser *Duration* than the supposed *Duration* is. But if *God* did act according to the necessity of *Nature*, no such *Duration* would be possible, because *God* acting necessarily, would only produce that which did follow from necessary *Action*; and consequently being unable to produce a greater, his *Power* would be *Bounded*, which is destructive of the *Idea* of *God*.

CHAP. XVI.

Concerning Gods Government of the World, and Providence.

I.
Supposing
God to be
All-know-
ing and
All-power-

From what hath been already said of the *Divine Attributes*, we may easily conclude that *God* is *Provident*, and the *Ruler* and *Governour* of all the *World*, and all things that are in it. For

seeing that he hath *Created* all things, and by his *ful*, he must alone *Power*, brought them into a State of *actual* also be *Pro-*
Existence, it seems to be Repugnant to his *Good-*
ness and *Omnipotence*, that he should neglect the care of them, and leave them to the *Government* and disposal of others. For since he is *All-know-*
ing, *All-powerful*, and supremely *Good*, he cannot but keep his *Eye* upon his *Creatures*, and govern and dispose of them for their good. For *Will* and *Power*, with respect to things without them, are not distinguished from the *Divine Understanding*; and since *God* hath decreed that at some certain time, *Creatures* should exist, he also determined them to exist so, as that their *Essence* and *Existence* might depend on his *Will* and *Power*, without being able to attain any *Ends* without his special *Providence*.

By *Providence*, *Divines* understand that *Eternal* *disposal*, by which *God* doth *Efficaciously* direct all his *Creatures* to certain ends foreseen by him, so as that in time they come to attain them. For *Pro-*
vidence doth not only denote the operation of the *Intellect*, by which a thing is foreseen before it be brought to pass; but also that of the *Will*, or the *Decree* and *Counsel*, whereby, before the *work* is done, it is disposed to the end appointed for it. And that such a *Providence* as this appertains to *God*, may be proved by several *Reasons*.

For First, it belongs to the *Nature* of *God* to be most perfect; but how can he be said to be so, without being present to his *Creatures*, and taking care for them? For it is without doubt a greater perfection to provide for the *Universe*, and to govern and dispose all things for the best, than to leave them to themselves, or to be disposed of by others. For by so much the more perfect any one is, by how much the more he excels others in *Command*, *Wisdom*, *Goodness* and *Liberality*: But if the care of the *World* should be supposed taken away from *God*, we shall make him an *Idle* and *Unactive Being*, as *EPICURUS* doth; and by this means shall be able to conceive a more perfect *Being*, who together with the highest *Felicity* has the *Sovereign* command over, and disposeth of all things, and whose *Tranquillity* is not disturbed or interrupted by the *Multiplicity* of the *Affairs* he manageth. Wherefore, since nothing can be admitted to be more perfect than *God*, we must conclude, that he takes the care of, and disposeth all things. For it is not becoming, as *DAMASCENUS* saith, that there should be one *Builder* or *Architect* of this *World*, and another that takes Care of it, forasmuch as this would Argue a disability in them both; in the one of *Making* or *Effecting*, and in the other of taking Care for and *Disposing* of it.

Secondly, Forasmuch as *God* is *Eternal*, having no Bounds of his *Existence*, it is necessary that his *Understanding* should be *Eternal* also, because it belongs to his *Essence* to be conceived by us as *Supremely Intelligent*: Now his *Understanding* is not distinguished from his *Will* or *Decree*, but only by *Reason*, or our meer *Conception*; therefore when we say that *God* understood, or knew all things from *Eternity*, we at the same time assert, that he also from *Eternity* provided for all things, and designed them to their appointed ends; seeing that his *Will* is *Supremely Efficacious*, and never fails of the ends he intends.

VI.
God's Pro-
vidence,
and Go-
vernment
of the
World, may
be proved
from the
things
themselves

VII.
How any
thing can
be said to
be by
Chance, if
all things
be ruled by
Providence

VIII.
Where-
as it is
God, no-
thing hap-
pens by
Chance.

V. The same may be confirmed from the rest of his *Attributes*: For if God be Sovereignly *Intelligent*, he must also be *most Wise*; and will not he be accounted more *Wise* by governing the *World*, and administering all things, thereby not only *Speculatively*, but *Practically* understanding them? If God be *most Powerful*, he must be able to do all things, so as that nothing may be in a condition to resist his *Will*, or escape his *Power*. But how can this be, except he govern the things he hath produced, and concur to their *Actions*? If he be *most Good*, sure it is necessary that all *Creatures* experience his *Goodness*: But how can that be, if he takes no *Care* of them, nor *Provides* for them? Therefore we must own the *Divine Providence*; forasmuch as without it, his chiefest *Attributes* are destroyed, and nothing is left whereby we may demonstrate his *Sovereign Power*, *Wisdom* and *Goodness*.

VI. Another *Argument* may be taken from the *Creatures* themselves. For whosoever considers the frame of this *World*, and the order of its *Parts*; whosoever takes a view of the *Earth*, the variety of its *Seasons*, the different *Shapes* of *Living Creatures*, the manifold *Virtues* of *Plants*; whosoever scans the *Fabrick* of the *Microcosm*, *MAN*, the multiplicity of his *Members*, with their admirable *Connexion* and *Harmony*: Whosoever takes a Prospect of the *Heavenly Bodies*, their *Lustre*, *Beauty*, constant *Motion* and *Proportion*, will be forced by his *Conscience* to acknowledge, that these *Wonders* could not be the product of *Chance* and *Fortune*, but the Effect of the *Great GOD*. And therefore *CICERO*, in his Book *de Natura Deorum*, speaks thus: *Shall we call him a Man, who beholding the certain Motion of the Heavens, the wonderful Order of the Stars, and all so filly link'd and suited together; shall suppose that all this is managed without any reason, and by Chance; when indeed we can never have any Conceptions of the greatness of that Wisdom and Counsel which disposeth all these things?* When we see any thing moved by *Springs* and *Engins*, as a *Sphear* or *Watch*, have we any the least doubt of their being the Effects of *Reason*? and when we see the *Heavens* moving with admirable *Swiftnes*, and constantly to persist in their *Motions*, finishing their *Anniversary Revolutions*, for the *Health* and *Conservation* of all Things; shall we question whether these Things are order'd and directed by a most *Excellent* and *Divine Reason*?

VII. Tho' no body that owns a *God*, can doubt of his *Providence*; yet this *Difficulty* remains to some, How any thing can be said to be by *Chance* in the *World*, if *God* governs all Things, and directs them to their certain *Ends*? And besides, How comes it to pass, that *God* taking *Care* of all things, his *Thunder* often spares the *Wicked*, and strikes the *Innocent*? Or, if every *Motion*, and all other things that keep their certain *Periods*, be called *Divine*, must we not also suppose *Tertian* and *Quartan Agues* to be such, whose *Motion* and *Returns* are so certain and constant?

VIII. There is no question, but that many things happen by *Chance* in the *World*, with regard to *Second Causes*; but nothing at all with respect to the *First Cause*, who disposeth and fore-ordains all things from *Eternity*. For *Chance* and *Fortune* are only in respect of him, who is ignorant of the In-

tention of the *Director*: And forasmuch as the *Divine Intention* is hid from *Man*, till the thing be done; therefore the same, with respect to *Man*, is said to happen by *Chance*, but not with respect to the *First Cause*. How many things seem to happen in a *Commonwealth*, which with reference to us are *fortuitous*; but not so with respect to the *Prince* who governs it, who order'd things so on purpose, and made use of such *Ministers* and *Means*, so as that things could not happen otherwise? And whereas it is further objected, That sometimes *Thunderbolts* pass by the *Wicked*, and light upon the *Innocent*.

IX. We are to consider, that all these things happen by *God's* particular *Direction*, for very good ends, which tho' they be unknown to us, yet are not we so therefore to deny them: For it is too great a piece of *Rashness*, to have so great an esteem for our own *Wit*, as that whenever we cannot find out the *True Cause* of any thing, we should presently suppose the *World* to be without a *Ruler*, and that the *Concerns* of *Men* are committed to the management of *Blind Chance*.

X. But you will say, If there be a *Cause* that presides over *Inferiour things*, why do we perceive such *Confusion* in the *World*? Why are the *Good* neglected and oppress'd by *Poverty*, *Slavery*, and *Dis-eases*; whilst in the mean time the *Wicked* flourish, and abound with *Honour* and *Riches*?

XI. This is the *Complaint* of most *Men*, who being ignorant of the *True Good*, are taken with the outside of Things: For if we attend to the *Nature* of *Good*, we shall find that *Vertue* alone deserves that *Name*, which whosoever wants, is worthily esteem'd *Miserable*. Hence it is that *Wicked Men*, being devoid of *Vertue*, do not make use of those outward good things with that *Moderation* of *Mind* as they ought, but in the midst of their *Riches* suffer *Want*, and in the midst of their *Pleasures*, *Pain* and *Torment*; so that they are not *True* good things to them, but in appearance only. But if on the other hand, *Evil things* happen to those that are *Good*, forasmuch as they are conducive to the exercise of their *Vertue*, they are rather to be accounted *Good things*, because by them their *Minds* are estranged from *Worldly Lusts*, and raised to the love and desire of *Heavenly things*. This therefore is the greatest Instance of *Providence*, when we see *Good things* bestowed upon *Ill Men*, that they may grow the worse; and *Evil things* upon *Good Men*, that thereby they may grow better.

XII. But you will say, That *God* created *Angels* and *Men*, whom he foresaw would fall and continue in *Evil* or *Wickedness*. St. *AUSTIN* answers, That *GOD* would not have created any *Angel* or *Man*, whom he foreknew would fall into *Sin*, if he had not known, at the same time, to what good *Ends* he could make use of them, and so compose the *Harmony* of this *Universe*, as a pleasant Song of *Discords* mix'd with *Concords*: For as these make the *Sweetness* of *Musick*, so the *Beauty* of this *World* is made up of these *Contraries*. And therefore in the *Third Book* of *Free-Will* he plainly teaches, That *GOD* ought not to have abstained from *Creating* of the *Creature*, whom he foresaw that by his own *Fault* (not by any of his *Creator*) should lose that *Beauty* in which he was created: For as a lost and wandering *Horse* is better than a *Stone*, which cannot wander, because it wants *sense* and *motion*;

so that *Creature* is more Excellent, which *sins* by its Free-will, than that *Creature* which doth not *sin*; because it hath no Free-will. And as I would commend *Wine* as good in its kind, tho' I blame the Man that is made *drunk* by it, and yet would prefer this *drunken* and *blamed* Man before the *praised*

Wine that had made him *drunk*. So likewise a *Bodily Creature* is to be commended in its degree and kind, whereas they are *Blame-worthy*, who by the immoderate use thereof, are turned aside from the Perception of *Truth*.

The Third Part OF THE INSTITUTION OF PHILOSOPHY.

VIZ. DÆMONOLOGY;

OR,
Of Intelligences and Created SPIRITS,
GENIUS's and DÆMONS,

Commonly called
ANGELS.

A Prefatory Discourse.

Of the Division of Created Things; the Definition of Pneumatics, or the Doctrin of Spirits, and its Certainty.

I.
The aim of
the Author
in this
Treatise.

Notwithstanding that to Treat of ANGELS does seem chiefly to belongs to *Divines*, and the consideration of their *Nature* and *Faculties* may be thought to exceed the Bounds of *Metaphysicks*; yet I think it may not be useless to try what *Natural Light* can do in this case, and how far by the Guidance thereof, we may discover their *Essence*, *Existence*, and *Operations*.

II.
Division,
a great
Help to the
Knowledge
of Things.

They who endeavour to search into the *Nature* of *Things*, take care to divide them, as fitly as may be, into those Parts which may be helpful to the obtaining a more distinct Conception of them. For *Division* takes away the doubtfulness of *Terms*, and makes that which before was confusedly perceived under one Name or Word, to be more clearly

understood by more Words, expressing the Parts of it.

It is notorious to all *Philosophers*, that *Created Things* are divided into *Spiritual* and *Corporeal*, or into *Thinking* and *Extended*. By the Name *BODY*, all *Material* or *Extended Substances* are understood, of what *Nature* soever they be, whether they be more *Gross* or *Subtil*; whose *Essence* consists of three *Dimensions*, or in *Extension* in *Length*, *Breadth*, and *Depth*. And we call that an *Incorporeal Substance*, or *Immaterial*, which is without *Extension*, and all those *Modes* and *Accidents* which accompany a *Bodily Substance*. Whence it appears, how very improperly the Name of *SPIRIT* is attributed to the *Air*, *Wind*, *Fire*, *Vapor*, &c. because these *Things* be more *Thin* and *Subtil* than others, yet don't they for all that cease to be *material*, *impenetrable*, and *indefinitely divisible*.

We

IV.
Quantity
cannot be
attributed
to Angels

We may also perceive with how little Reason some do attribute Quantity to Angels and Human Souls, and conceive one part of them to be without another, as if they were Material. Whereas if a Man consider a Corporeal and Intellectual Substance, he will find them to be distinguished by Properties and Attributes, and to have no affinity at all with each other. For what Similitude can there be supposed between a thing extended, and a Being devoid of all Extension? Or what agreement is there, between a Substance that understands, wills, and imagines, and that which is divisible into parts, and is diversified by Figures, and which is commensurate to a certain space and Place?

V.
Substance
is wrongly
divided by
some into
immaterial
and Bodily.

Others divide created Substance into Immaterial and Corporeal; but this Division doth not seem to be exact, or made according to the Rules of a right Division: because Immaterial and Incorporeal being Negative Terms, can represent no positive Idea to our Mind, such as is desired by all, where it may be had. For Negative Words represent no Properties or Attributes to our perception, and rather tell us what the thing is not, than what it is. True it is, that this Division is set down by many Philosophers of great note: but so far as a Privative or Contradictory opposition (which those words do import) cannot have place in a lawful Division, this is not to be admitted. Moreover this Division seems to be grounded on this childish mistake, that the Substance of Material things is more real, than that of Spiritual; and that therefore the former, as more perfect, are expressed by Positive words, but the latter, as more imperfect, by Negative.

VI.
It better
divided in
to Thinking
and Ex-
tended.

Wherefore Created Substance is more fitly divided into Thinking and extended, or into Intellectual and Corporeal; because then the Dividing parts, are apprehended by Positive conceptions, and expressed by Positive Terms. For without doubt, we shall have a more clear notion of an Angel by conceiving him Intelligent, Willing and Powerful, than by apprehending him Immaterial, Incorporeal and Invisible. Forasmuch as these Negative Attributes, as I said, rather declare what an Angel is not, than what he is. Besides, he that perceives the Positive Properties of a thing, does by consequence understand the Negative; but not on the contrary: For he that knows an Angel to be Intelligent, doth at the same time know him to be Incorporeal and Invisible; but tho' he understand him to be Incorporeal and Invisible, he does not therefore understand him to be Intelligent; for the Air is Invisible, and yet is neither Intelligent nor Incorporeal. Wherefore created Beings are very properly divided into Intellectual and Corporeal or Material, for no substance can be conceived by us, which is not either Thinking or Extended, or in other words, which is not Active or Passive. Hence St. AUGUSTIN saith, Amongst things, some thing is acted, and not Acting, as a Body; another is Acting, and not Acted, as is God; and a third Acting and Acted, as are all Spiritual Substances.

VII.
The Distri-
bution of
Science
Universally
of Bodies, and
PNEUMATICA,
or the Sci-
ence of Spirits:
Which may again
be subdivided
into other Species,
according to the various no-

As all created substance is divided into Material and Intellectual, so the knowledge of that Substance is distinguished into SOMATICA, or the Science of Bodies, and PNEUMATICA, or the Science of Spirits: Which may again be subdivided into other Species, according to the various no-

tions under which a Body or Spirit may be considered. For as a Body is conceived by us, either as Natural, or as Artificial, or as having Quantity, and being Figur'd, or as subject to Sickness and recoverable; so accordingly divers Species of Sciences are constituted. Natural Philosophy considers a Body as Natural, and explains its Essence and Properties. Mechanical Science Minds the outward frame and structure of the Body, and the figures it obtains by workmanship and Art. Mathematicks take to task the various Modes of a Body, as the figures which bound it; the situation of one part with reference to others; the Motion or change of situation; and Rest or continuance in one place. Lastly, Physick or Medicine considers the Body as subject to Diseases and recovery, and endeavours to maintain the health, or to restore it when lost.

In like manner as Intellectual Substances are divided into God, Angels, and the Souls of Men; so Pneumatica is divided according to the Diversity of the objects it contemplates into Natural Theology, Geniography or the science of Angels, and Psychology, or the Doctrine of the Soul. Natural Theology considers the Essence of God and his Attributes; Geniography the nature of Angels and Intelligences; and Psychology examines the constitution of the Mind of Man, its Faculties and Passions. So that Pneumatica is nothing else but the science of Spirits, which admits of divers names, as it Considers God, the Angels, or the Soul of Man.

The certainty of this science is very clear from its Definition, because it treats of Incorporeal things, and such as are not subject to change: For if Natural Philosophy which treats of a Natural Body, and Mathematicks which handles the Modes that follow it, deserve the name of Science, because they are founded on Axioms of Eternal Truth, much more doth the Doctrine of Spirits, deserve the name of True Science, forasmuch as it is not only grounded on General Propositions, but likewise borrows its certainty from the Object it considers, and deduceth clearer Conclusions thence, than Natural Philosophy doth from a Body or extended Substance. For tho' the vulgar sort of Mankind is apt to be mistaken, and doubtful about Immaterial Substances, whether they do really exist, and think that the name of Thing ought only to be attributed to Bodies; yet the Lovers of Wisdom do own Thinking Substances, to be much truer, and much more real than any Bodily or Material Beings.

CHAP. I. Of the Nature of Angels.

THE Division of created Substance into Thinking and Extended being supposed, it will not be difficult to conceive what a Spirit is, and how it is to be distinguished from other things. For the Word Spirit is here to be taken in its most proper sense, for such a substance as is endued with the Faculty of perceiving and willing. Because, as the formal Reason of a Body consists in Extension, which is always attended with Divisibility and Impenetrability; so the essence of a Spirit consists in this that it is a Thinking Substance, the concomitants whereof are Indivisibility, Perception and Volition. And as a Body cannot be conceived without

VIII.

of Spirits.

I.
What we
are to un-
derstand by
the Name
of Spirit.

Extension, so neither can a *Spiritual Substance* without *Cogitation*: And therefore it is necessary that *Cogitation* do constitute a *Spirit* in its *spiritual* Nature, as *Extension* constitutes a *Body* in its sensible and divisible Nature. Forasmuch as according to *ARISTOTLE*, that is suppos'd to belong to the *Essence* of any thing, without which it cannot be understood.

II. And whereas some suppose they cannot conceive an *Angel* without *Extension*, and so confound the Notion of *Substance* with that of *Extension*; this proceeds only from a false prejudice they have entertained, viz. that there is nothing *Intelligible*, but what is likewise *Imaginable*, which certainly is a very great mistake; for *Angels* and all other *Spiritual Substances*, cannot be reached by our *Imagination*, but only by our *Intellect*. For all Men generally take an *Extended Being*, to be somewhat *Imaginable*, in which there are various parts of a determinate *Magnitude* and *Figure*, and whereof the one is not the other; which Notion in no wise can agree with *Spirits*.

III. By the Name *Spirit*, therefore we are here to understand a *Finite Thinking Substance*, altogether independent on, and free from *Matter*: Under, which *Angels*, *Demons* and *Intelligences* are comprehended; neither is there any Distinction between them, save only that the *Angels* are Good, and the *Devils* Evil; that these aim at the *Destruction* of *Mankind*, the other assist their *Salvation*; these abide in *Sin*, the others continue in *Grace*; these are bound in *Hell*, the other enjoy the *Vision* of *God* in *Heaven*: All other things, as *Essence*, *Existence*, *Knowledge*, *Power*, the taking up of *Bodies*, *Talking together*, &c. being common to them both.

IV. From the Definition of a *Spirit* or *Immaterial Substance*, we may with great Evidence conclude, that *Angels* are *Pure Spirits*, or as *DIONYSIUS* in his fourth Book concerning *Divine Names*, saith, *Free from Matter*, and *Incorporeal*. Because a *Thinking* and an *Extended Substance*, are altogether distinct from each other, so that the one of them can be clearly perceived without the other. For we most clearly perceive a *Spirit* or *Thinking Substance* without a *Body*; and on the contrary, a *Body* without a *Spirit*. Now things that are thus distinguished, cannot agree to one and the same Subject: Because these *Attributes* are altogether different; and there can be no greater opposition between *Attributes* of *Substance*, than *Diversity*. And therefore to say, that *Extension* and *Cogitation* agree to one and the same Subject, is in effect to affirm, that one and the same Subject can have two *Natures* or *Essences*, which cannot be said of a Simple thing without a Contradiction. Because *Cogitation* and *Extension* are not only two *Essential Attributes*, but also constitute the nature of the thing to which they are attributed, and are more inconsistent, than *Blackness* and *Whiteness*, *Heat* and *Cold*, in the same Subject. For *Heat* and *Cold* may succeed one another in the same Subject, and the same thing which is *Cold* now, may afterward become *Hot*: But it is altogether Contradictory that *Cogitation* and *Extension* should be in the same simple Subject, and constitute two *Natures* at once, or Successively.

V. Moreover, if *Angels* were *Material*, they might be divided; for *Divisibility* is a Concomitant of

Extension; but *Angels* are not *Divisible*, therefore they are not *Corporeal* or *Extended*. The *Minor* is thus proved: The *Essence* of an *Angel* consists in *Cogitation*, which admits of no *Division*; or no body can conceive the half of a *Thinking Being*; wherefore *Angels* are exempt from *matter*, and from any *Corporeity*, how subtil soever the same may be conceived.

VI. The *Immateriality* of *Angels* may be made out from some *Effects* that exceed all *Human Power*, and the utmost activity of *Bodily force*: Such as are the *Antient Idol Oracles*; the *Speech* of *PEOPLE* *POSSEST*, which are often in those *Languages*, which the possessed party does not understand; the *Penetration* of *Bodies*, and such like, which are an incontestable proof of *Intelligent Natures*, and which exert their *Activity* without the help of any *Body*. Besides we Read in *Scripture* that a vast multitude of *Devils* entred one *Body*, *Mark* 5. yea, a whole *Legion*, which according to the most common Account contains 6666, which is absolutely impossible, if the *Devils* have *Bodies* and take up a determinate place.

VII. They who assert *Angels* to be *Compound Beings*, and to have *Bodies*, tho' much purer, and of a more subtil matter than ours, endeavour to confirm their Opinion from *Gen. 6.* where it is said, that the *Sons of God* came in unto the *Daughters of Men*, and they bare *Children* to them, and the same were *Mighty Men* or *Giants*. Which could not be, except we suppose the *Angels* to have *Bodies*; *Spirits*, as purely such, being incapable of *Generation*.

VIII. But this place is wrongly interpreted; for by the *Sons of God* in that place we are not to understand *Angels*, but the *Posterity* of *Seth*, who imitating the Pious conduct of *Enos*, did worship *God*, and call upon his Name; but their *Posterity* degenerating from the Piety of their *Fore-fathers*, and plunging themselves into *Carnal Concupiscence*, joyned themselves with the *Daughters of Men*, that is, with *Cain's* *Posterity*; from which *Conjunction* *Giants* were born, that is, monstrous and deformed *Bodies*, as a Punishment of their *Lust*. For it is contrary to Reason to suppose, that *Angels* can Generate. Wherefore, the *Fathers* of these *Giants* were not *Angels*, but *Men*, as the *Scripture* sufficiently declares, *Gen. 6. 3.* My *Spirit* shall not always strive with *Man*, for that he is *Flesh*.

IX. But will some say, if the *Angels* be altogether exempt from *Composition*, and any *Matter* whatsoever, they will be as Simple as *God* himself, as being the one as well as the other *Pure Spirits*, having only an *Essence*, and some *Modes*, which do not hinder *Simplicity*.

X. To which I Answer, that tho' neither in *God*, nor the *Angels* there be any *Composition* of *Matter* and a *Substantial Form*, yet are not the *Angels* exempt from all other *Composition*, as consisting of *Potentiality* and *Act*, of *Essence* and *Existence*. Which *Composition* is not to be found in *God*, forasmuch as the *Divine Modes* are only distinguished by Reason (that is, our way of Understanding) from the *Essence* of *God*. Wherefore the *School-men* call *Angels* and *Souls* *Impure*, and *Imperfect Acts*, but *God* the most *Pure* and perfect *Act*. Hence it is that *DESCARTES* in the 23 Article of the first Book of his *Principles*, Teacheth, that our *Mind* (and the same is to be understood of *Angels*) doth

Some think there is no Substance but what is Material.

Spirit is a general name to Angels and Demons.

The Angels are Immaterial Substances.

Forasmuch as Angels

are indivisible, they are likewise incorporeal.

VI. The effects of Angels proves their Incorporeity.

VII. Whether Angels be capable of Generation.

VIII. What we are to understand by the Sons of God in Scripture.

IX. Objection that the Angels will be equal to God in the Simplicity of their Nature.

X. The Simplicity of God is very different from the Simplicity which is in Angels.

doth understand, and will, by Operations that are in a manner distinct; whereas, God by one and the same most Simple Operation, doth Understand, Will and Act,

XI.
Angels do not understand all things actually.

Besides, Angels have not actually all the Cogitations they can have, seeing that many things can be Revealed to them by God, and we understand them to have many Thoughts potentially only; so that at the same moment of time, they are conceived as Thinking in part Actually, and in part Potentially. Which is sufficient to denominate them Compounded, and excludes them from the Simplicity which is in God.

CHAP. II.

Whether the Existence of Angels be demonstrable by the Light of Nature, and how the same may be Evinc'd.

I.
The Ancient Philosophers believed Angels.

IT was the constant Opinion of the Ancient Philosophers, that there were Demons and Genii or Intellectual Substances, which did preside over the things of this World, and were the managers of Heavenly things also, as so many Divine Ministers. For they thought it not becoming the Majesty of God, to Administer the World by himself, but that he made use of Ministers and Servants, in the discharging of so many different Offices. For should God be thought inferiour to the King of Persia, who residing at Susa or Hispahan, Govern'd his large extended Empire, and by the Hands and Heads of others, was every where present with his Subjects, provided for them, and defended them? Seeing therefore that God hath his Ministers, they must needs be Spirits, that is, most active and ready to expedite his Commands: But how can they be such, if they be clog'd with the weight and cumber of a Body? Whence they conclude, that there are Angels, which are call'd Genii, forasmuch as they assist Men; and Demons as they are the Administrators of this lower World; this is confirmed by a Verse quoted by CLEMENS ALEXANDRINUS, and ascribed to ORPHEUS.

Standing about thy Throne the Angels are,
Who of Mankind do take the Active Care.

By this way of Arguing it appears, that the Ancient Philosophers did believe Angels, tho' it does not prove that they really Exist; forasmuch as all those things, which they commit to the care and management of Genii and Demons, may be done by God alone. Neither indeed is it unbecoming the Divine Majesty, by his own Power to provide for his Creatures, without the assistance of any Ministers, to share in the Burthen of the Government: For God being Omniscient and Omnipotent, always chuseth that which is best, and therefore does not stand in need of any Angelical Assistance, in the Execution of his designs. And if there be any Intelligences in the World, that perform his Commands, that is because God thinks it best, and most conducing to that State of the World, which in his Wisdom he hath allotted it, that so the Universe should be a kind of Commonwealth, wherein He as Lord paramount, should Govern and Administer all things, especially the concerns of his Rational Creatures by the Mediation of Angels, as subordinate Magistrates under him.

Neither indeed is it so easie a matter, to prove the Existence of Angels by the Light of Nature

only; because tho' we have a clear and distinct perception of Spiritual things, as they are Thinking Beings, and distinguished from things extended; yet forasmuch as their Existence is only Possible and Contingent, all that we can infer from thence is only thus much, That Angels may Exist, but not that they do really so. For if the Existence of Angels could be demonstrated, it must be by an Argument a Priori, when we demonstrate any thing by its nearest Efficient Cause; but so we cannot prove, that God the Maker of all things hath Actually Created Angels, since Creation depends on the meer Good Pleasure of God, which cannot be known to any without a Special Revelation.

Wherefore we can have no certainty of the Existence of Angels, save only from their Effects, or other signs that argue their presence. Thus we may prove, that there are Angels, from Persons Possessed, who tho' they be altogether Ignorant and Illiterate, do notwithstanding Speak strange Languages, and Discourse of several things beyond their Capacity; declare what is done by Persons far absent, and are carried through the Air, notwithstanding the weight of their Bodies. Who can deny, but that all these things must be performed by Spirits, since they Transcend the Activity of Bodies, and the Power of Nature?

The Existence of Angels is confirm'd by the Answers of Idols, and the Predictions of Soothsayers, and those unwonted Motions, the Cause whereof cannot be assigned, unless we should say, that they are produced by such Invisible Agents. For we must not say, as some do, that these Effects may be produced by the First Cause; because God never Thwarts himself, nor does any thing Derogatory to his Glory, as are the Idol Oracles, and things done by Persons that are Possessed.

It is a received Axiom amongst the Ancient Philosophers, That a Body cannot move it self, or that whatsoever is moved, is moved by another: Wherefore there must be allowed some Active Principle, that may move Matter. For evident Motions must have a Cause, which cannot be Coporeal; for so the Question would return, By what Principle that was moved, and so to Infinity, till we come to some Immaterial Cause. Hence it is, that ARISTOTLE and other Philosophers hold, That Intelligences move the Heavenly Bodies: And consequently, that the Superior Bodies communicate no other Motion to Inferiors, but what they have first received from the Angels.

Neither do we want very probable Conjectures of the Existence of Angels, if we consider the Harmony and Order of the World, and how its extreme Parts are linked together, by Intervening Middle Parts. For since we see some things in the World, that are Compounded of a Thinking and Extended Substance, as Man, who consists of Soul and Body; it seems very Rational, that as there are things that are altogether Bodily, or that include nothing but Extension; so on the other hand there should be Spiritual Substances, whose Idea involves nothing but Cogitation.

This may be confirmed from divers Apparitions of Angels mentioned in Holy Scripture, which happened in divers Places and Times: Thus, they appeared to Jacob as he was on his Journey, Gen. 32. To Zachary in the Temple, Luke 1. To Guideon in his Fathers Ground, Judg. 6. To our Saviour in the Garden,

Angels cannot be demonstrated a Priori.

IV.
The Existence of Angels proved from their effects.

V.
Soothsayers and Oracles prove the Existence of Demons.

VI.
From the inactivity of Matter, we may infer, there must be Spirits to move it.

VII.
Reason convinceth us of the Existence of Spiritual Substances.

VIII.
Apparitions of Angels.

Garden, Luke 22. To the Childeren in the Fiery Furnace, Dan. 3. In the Prison to Peter, Acts 12. At our Lords Sepulcher, Mat. 28. In the Wilderness to Hagar, Gen. 21.

CHAP. III.

Of the Faculties of Angels, and first of their Understanding, and its Object.

I. *A thinking Nature hath two Faculties.* Intellectual Nature hath two Faculties, Understanding and Will, which are as it were its Properties, and inseparable from it. The first of these perceives Objects by contemplating the Notions, it finds in it self; the other determines an Intelligent Being, to the embracing or avoided of a thing, or to suspend its Judgment, where the thing is not sufficiently understood. And forasmuch as these Faculties are distinguished at least by Reason, and are variously conversant about their Objects, we will also separately handle them, speaking first of the Understanding, and afterwards of the Will. Because it will conduce much to the discovery of the nature of Angels to know how far their Knowledge and Wills do extend.

II. *The Various objects of Angelical knowledg.* As to the Object of Angelical Understanding, the Schoolmen dispute, First, whether Angels and Devils do understand the mysteries of grace by their natural ability. Secondly, whether they know the Thoughts of men, and can penetrate the secrets of their Hearts. Thirdly, whether they know Future things. The First Question I leave for Divines to determine, contenting my self to speak a few words to the two latter, which do not exceed the Bounds of Philosophy.

III. *The Common opinion of Schoolmen concerning the knowledge of Angels.* As to the second Question, viz. whether Angels know Mens thoughts? the common Opinion is that Angels and Devils cannot naturally know the Thoughts of Men without their consent. The Cause of this hiddenness of Mens Thoughts, some ascribe to the Free Will of Man; others to the Abyss of Mans Heart; others to the Will of God, who denies his Concourse to the knowing of them; others to the nature of Mens thoughts, which cannot objectively occur to others without the Will of him that thinks them.

IV. *The common opinion refused.* But indeed all these Reasons are very weak, and do not at all prove that the Thoughts of Men are inscrutable by Angels; because the Perceptions and Determinations of Mans Mind, are in themselves no less Natural, than the very nature of Angels. And therefore as an Angel beholds his own thoughts, there seems no Reason, why they should not as well perceive those of other Angels and Men, seeing they agree in Substance. Besides, it cannot be doubted but the Angels understand their own thoughts, and those of others too, with their consent: But the Identity or Sameness of subject, or anothers consent, doth not encrease the Faculty, or communicate any perfection to it, or render the understanding Faculty more proportionate to its Object; wherefore if Angels by the consent of another can penetrate his thoughts, they may as well without it. Neither is it any objection against this, that humane Actions are free, and depend on their Wills, because all the forementioned difficulties recur also upon this: And this only seems deducible from it, that Angels know such Acts as these to be free, and like to those they themselves produce. But who will say that Elicit Acts

have such a dependence on the will that they cannot be known by another, without the consent of him that Elicits them, seeing there is no difference between Acts that are free, and such as are not free; and that the same Act may successively change its nature, and of Free become Necessary? Wherefore I think we may conclude, that as Angels can know Acts that are not free, so likewise may they those that are free.

Wherefore let this stand fast, that Angels can perceive the Thoughts of Men: For seeing that Angels are Intellectual Substances, and that the Perception of the Understanding and Determination of the will, are the operations of Intellectual Faculties, there must needs be a Proportion between them. Besides, there are but few determinations of our will, which are not discovered by some signs, as by the motion of Spirits about the Heart, or by some outward tokens, which may give an occasion to Angels and Devils to discover the Thoughts and Affections of the Heart. But if all those signs were taken away, yet there is such an Agreement or Correspondence betwixt the Operations of the Mind, that they cannot but naturally perceive the Conceptions of our Understandings, and Decrees of our Wills. I my self some few years since heard a Devil speaking out of a possessed Woman at Brussels, who revealed the inward thoughts of many that came to her, tho' they were not discoverable by any sign. And when one of the standers by asked the Spirit, What it was he thought of at that instant? He told him that he resolv'd to take a Journey the next day, which he could not deny, but it was for. Neither needs this seem strange to us, seeing that we our selves would know as much if we were not shut up in these Bodies; and therefore are our thoughts hidden from others, because the Eyes of Men cannot pierce into our Breasts, which by reason of their materiality, are impenetrable. And it is probable that when some of the Holy Fathers deny'd the knowledge of Mens thoughts to Angels, it was for no other reason, but because they held them to be material.

VI. If you say that this Opinion seems contrary to Scripture, I Kings 8. 29. ver. For thou only knowest the Hearts of all the Children of Men. And Jerem 17. ver. 9. The Heart is deceitful above all things, and desperately wicked, who can know it? I the Lord search the Heart and try the Reins. In which places by the Heart are meant the secret thoughts, and whatsoever immediately depends on the Mind.

VII. This Objection is easily answer'd by saying, that the Scripture in these places doth distinguish God from Men, with respect to the knowledge of thoughts, but not from Angels and Devils. And whereas Holy Writ seems to attribute this Priviledge to God only, not to Angels; this is, because it considers the Angels as Gods Ministers, and therefore ascribes to God whatsoever is done, or perceiv'd by them.

VIII. As to the Third Question, whether Angels know things to come? We are to suppose that this is not to be understood of a knowledge of Futurities that are not to be gather'd by conjecture from probable Causes; as a Master of a Ship foresees a Tempest, or a Physician the probable Event or Issue of a Disease; or a General the Event of a Battle, but of the Knowledge

V. That Angels do penetrate the secrets of Mans Heart.

VI. An objection on from Scripture.

VII. Answer.

VIII. By the knowledge of Future things, we are not to understand that which is gather'd by conjecture.

Knowledge of things that are merely Fortuitous and Contingent, which have no causes, or which are the effects of *Mans free will*; as that *John* will be kill'd by a Tile falling from a House; or that *Peter* is to take a Journey to morrow.

IX.
Angels naturally cannot foreknow future things.

I say therefore that neither *Angels* nor *Devils* do foreknow future Contingencies, which either have no certain Causes, or depend on Free will. The Reason is because an Effect must be known either in it self, or in its cause; but these Futurities cannot be known either way, and therefore cannot be known by *Angels*. That they cannot be known in themselves is evident, because they are not determin'd, neither have any necessity of existing; nor in their Cause, for that is free, either to produce or not to produce an effect. This may be further confirm'd thus; *Angels* are ignorant what themselves shall act, before they have resolv'd it with themselves, and therefore much less do they know what others will do. And therefore some *Schoolmen* are of Opinion, that the *Devils* did not foreknow their Fall, nor the Miseries consequent upon their Sin.

X.
Yet they may probably Conjecture of things.

Yet it cannot be deny'd but that *Angels* and *Devils* may know many things by conjecture; since they can have a great insight into the Temper and Propensity of men, by knowing their Manners, and discerning the resolutions and thoughts of their mind by external signs and tokens.

CHAP. IV.

Of the Will of Angels.

I.
What the Will is, and whether it be found in Angels.

THE Will is here taken for that Power or Faculty whereby an Intellectual Nature produceth all its actions and thoughts that are of choice and determination, from himself without any force or compulsion. For it is the nature of a Thinking Being, that consider'd in it self, it can do something, and determine it self to Act or not to Act. Now this determination proceeds either from the things themselves, without the Intellectual nature, or from the Intellectual nature it self. The Actions which have no other Principle, besides the Thing that Thinks, are called *Volitions*; and the Intellectual nature as it is to be consider'd to be an Elective Faculty, and a sufficient Principle to produce such Actions, is called *Will*. Now, that such a will is to be found in *Angels* cannot be question'd, forasmuch as they are Thinking Substances, or Beings that of their own nature have a Power of Willing and Nilling.

II.
Two Doubts about the Will of Angels.

Concerning the will of *Angels* it may be enquired, First, whether this Active Power in them be free, and without force, from any thing that is External: Secondly, whether the *Angels* have such a power over their Thoughts, that they can cease from all Perception and Judgment.

III.
The Will of Angels is free.

As to the First it seems certain, that the Will of *Angels* is free, and cannot be forc'd by any Agent to do any thing, or leave it undone; because the Nature of the Will consists in its being free, so that it implies a contradiction for it to be forced by any External Agent, since no Agent can destroy the Nature of another, which would then be, if the Will should will any thing with reluctance. Besides, the original of this Freedom comes from hence, that it is the very *Angel* himself, that determines himself, and wills this thing or the other; so that it depends on his own meer

Will, that he freely Wills or Nills. Moreover, The Will, and Free Will, if well look'd into, are one and the same thing, and differ only in this, that the Will is understood to be the Chusing or Elective Power, by which a Cogitative Being doth determine it self, and perform all his Motions and Actions that proceed from the said Will: And by Free Will, we understand the same Faculty, forasmuch as it hath the Power of Chusing. Now since both these are found in the *Angels*, they must by consequence also have Free Will.

IV.
An Objection against the Liberty of Angels.

If you Object, That the *Angels* do infallibly follow and embrace the Good they know; and that therefore *Divines* say, That they Love GOD so, as not to be able to turn their Love from him: Because by Grace they are so united to God, that they cannot be separated from him, and are so satiated with the Divine Glory, that they cannot be drawn from the Enjoyment of so great a Good.

V.
The Objection Answer'd.

I Answer, That notwithstanding all this, the *Angels* still continue Free, and Love God freely; because the Essence of Liberty doth not consist in Indifferency, but in the free determination of the Will, by which an *Angel*, or the Mind of Man, is so carried towards that which is propounded to it by the Understanding, either in Affirming or Denying, Embracing or Avoiding, as not to be determin'd thereto by any outward force. For the Indifferency of the Will only then takes place, when there are no Reasons to sway the Mind one way more than the other; which State is the lowest Degree of Liberty, and argues no Perfection in it, but only a Defect in its Knowledge. For who can deny, That Man doth nothing more voluntarily, than those things in which he finds not the least cause of Doubting? Wherefore *Des Cartes* concludes in his 4th Meditation, That Divine Grace, or Natural Inclination, do never diminish Man's Liberty, but rather increase and strengthen it; and that a Man ought to be accounted so much the more Free, by how much the more he is byass'd one way; either because of his clear discerning of the Goodness and Truth that is in it, or because God so disposeth his Thoughts. Wherefore, when the *Angels* do inseparably adhere to God, and are link'd to him by stable Eternity, as *Divines* express it, they do not by this means lose their Liberty, but by Grace are inclined to one part; and tho' indeed their Indifferency be diminished, yet their Liberty is rather increased, since to act Freely, and to act Voluntarily, are one and the same thing.

VI.
Liberty may be considered two ways.

The Matter will be more evident, if we consider the Liberty of Voluntary Actions, either before, or in the same moment they are exerted: If the Actions of the Will be considered before they be exerted, there is no question, but that the *Angels* have power to determine themselves to one or the other Contrary, that is, to prosecute or avoid one and the same thing. Yea, according to some *Divines*, the *Angels*, whether Good or Evil, daily change their Wills. The latter, when they surcease their Temptations, finding that they are of advantage, rather than any hurt or hindrance to good Men. The former, when they forsake the Wicked, whom they find they cannot reclaim from their Impiety. But if we consider Liberty in Voluntary Actions the same Moment they are exerted,

to it contains no Indifferency, in what sense soever it be taken; whether for that State wherein the Will is not prompted to embrace one thing rather than the other, by any knowledge of the Truth, or Goodness of them; or whether it be taken for that Positive Faculty of Intellectual Nature, whereby it can chuse, which it pleaseth of two Contraries. Because that which is a doing, cannot but be a doing at the same time it is a doing. And the Liberty which Angels have is such, as according to the increase of their Faculty of Acting, as was said before, is increased and strengthened.

VII. The Angel's Will is not determin'd to one Action.
As to the Second Doubt, Whether the Will of Angels be determin'd to elicit any Action; or whether it can at its pleasure omit the same, and be void of all Thoughts? I Answer, That the Will of Angels is not ty'd to any certain Action, as being Indifferent of its own Nature, and not bound to any certain Knowledge, since they neither love themselves, nor God necessarily, as their Natural End. Yet they cannot at their pleasure rid themselves of all manner of Thoughts, as some think they may, because it is the Nature of a Spiritual Substance to Think always; and therefore it implies a Contradiction, for an Intellectual Creature to be without all Thoughts, seeing we understand nothing else by the Name of Spirit, but a Thinking Being.

VIII. An Angel Thinks, whilst he commands himself to cease from Thinking.
If any one urge, That an Angel may abstain from all Thoughts, by commanding his Understanding to leave Thinking. I Answer, That this very Command or Will not to Think, cannot be exerted by an Angel without his being conscious to it, and consequently without his Thinking. For to Will is as much a Thought as to VVill; wherefore Angels cannot cease from all Thoughts.

CHAP. V.

Concerning the Power of Angels, as to the moving and producing of Bodies.

I. There is a Faculty in Angels, to move Bodies.
BESIDES the Operations of the Will, mention'd in the foregoing Chapter, there is another whereby a Spirit doth move a Body, and acts upon another Spirit like it self. For this Faculty is so intimate to a Spirit, that it cannot be conceived without it. We may indeed understand a Spiritual Substance, without the Power of Moving a Body, or of acting on another Spirit, in the same manner as we may understand a Spirit without the Faculty of Perceiving or Willing, which are two Modes of Thinking: But we cannot understand a Faculty of Moving it self, or from its own strength, without a Thinking Substance. And therefore we rightly conclude, That the Faculty of Moving a Body, and Acting upon a Spirit, do belong to Intellectual Nature, and is one Mode of Thinking.

II. The Point confirmed by Examples fetch'd from Scripture.
That this Power is in Angels, seems unquestionable; forasmuch as Holy Scripture doth witness, that several Bodies have been translated from one place to another by the Help of Devils or Angels. Thus we find the Prophet was Transported from one place to another by an Angel; the Body of Christ by the Devil, to the Pinnacle of the Temple; the Stone remov'd from our Saviour's Sepulcher; and other like Examples, which prove Angels to have the Power of Moving Bodies.

III. How Angels move Bodies.
There remains only one Difficulty to be explained; How Angels, that are Immaterial, can move Bodies, seeing they impress no Quality upon them, neither do communicate ought to the Thing moved, as Bodies do.

IV. Answer.
I Answer, That Angels move Bodies by their Wills, neither is there any thing else required to it. For tho' God (as shall be explained in our General Physiology) be the Universal Principle of all Motion whatsoever; yet this doth not exclude Particular Causes, that have a Power of Moving Bodies, according to that degree which God hath been pleas'd to impart with their Wills. And tho' it be difficult to comprehend how a Spirit doth act on a Body, and move it; yet are we not therefore to make a Doubt of it, only because we are ignorant how it is done.

V. We meet with the same Difficulty in our selves.
Indeed, if we duly weigh the Thing, we experience the same thing in our Selves: We find that our Soul moves our Animal Spirits, and directs them into the Nerves and Muscles, meerly by the Inclination of the Will it hath to excite this or the other Motion in the Body. And we experience also, That the Motion of our Spirits, Muscles, and Nerves, is consequent upon this Propension of the Will; and yet all this while our Soul doth not understand, how and after what manner our Soul, being an Immaterial thing, moves a Body; and therefore neither is it any wonder, if we do not know the manner how Angels moves Bodies: In like manner neither do we understand, how from a certain Motion of the Spirits and Blood, the Affections of Hunger and Thirst are stirred up in us, tho' we plainly feel them of our selves. Wherefore we are certain that Angels, being Spirits, move Bodies by their VVill, tho' the manner how, be hid from us, as being one of those things our Understandings cannot reach.

VI. Angels may Generate Bodies.
Neither do Angels seem to be destitute of the Power to produce and generate some Bodies. For since Generation is performed by Motion, and that nothing else is required to Generation, but a fit and suitable adaption of Parts, according to the Constitution of every thing; there is no sufficient Reason, why we should deny Angels such a Production. For in the Generation of a Plant or Animal, no new Substance is procreated, but only the Particles, whether Sensible or Insensible, acquire a new Connexion, and are otherwise disposed with relation to their Magnitude, Motion, Rest, Figure, and Situation; after the same manner as a House or Watch, which are framed without the production of any New Substance, by the fit joyning of Parts before existing. And seeing Angels have the Power of moving, agitating, and reducing Bodies into order, neither can we deny them the Power of Generating them. Besides, Angels having great knowledge of Natural Things, by the study of their Virtues and Dispositions so many Thousand years, they cannot be ignorant at what times, in what places, with what Measure the Qualities of things are to be temper'd, and what will be the product of the Mixture of such and such Particles. Besides, we see Men, who are much inferiour to the Angels, produce divers things, which before were not extant, and which would never have been so without their Industry. Wherefore we must conclude, that Angels will be much more able to do so.

VII. This is prov'd, because *Magicians*, by the assistance of *Devils*, have produced some *Animals*, as *Frogs*, *Serpents*, *Dragons*, &c. So the *Scriptures* tell us that the *Magicians* of *Egypt* turn'd their *Rods* into *Serpents*, *Exod. Chap. 7*. Now that these were true *Serpents* appears hence, because the *Scripture* tells us, That the *Serpent* into which *Aaron's Rod* was turned, devoured the *Serpents* of the *Magicians*: For otherwise we must acknowledge, that *Moses* his *Miracles* were meer *Impostures*, and false *Appearances*.

VIII. If you say, That we cannot rightly argue from the *Natural Perfection* of *Angels*, that they have *Power* of producing *Animals*; since we see that *Men*, who by many degrees excel *Mice*, *Gnats*, &c. yet cannot produce or generate them.

I Answer, That this *Impotence* in *Man*, does not proceed from his *Inability*, but from the defect of *Matter*, proper for the procreating of such *Animals*. For every *Body* cannot be framed of every *Matter*, but of such only as *Nature* hath appointed for that purpose. For as a *Stone-Cutter* can do nothing without *Sand* and *Stone*, tho' he hath the *Power* of *Squaring* and *Polishing* them; so seeing that *Man* is destitute of fit *Matter* for the *Generating* of *Animals*, it is no wonder that he cannot produce them. Neither doth it oppose this, that divers *Plants*, *Fruits*, and *Flowers*, do arise from the *Seeds* that *Man* casts into the *Earth*: For if a *Man* had the *Seeds* of *Living Creatures*, and committed them to places suitable to their *Nature*, he would produce proportionate *Animals* from those *Seeds*. We may conclude therefore, that *Angels* understanding the *Virtues* of *Herbs*, *Juices*, *Metals*, *Animals*, and *Men*, may take whatsoever is required to the *Composition* of *Bodies*, or *Animals*, and disposing the same in a fit place, produce or procreate them.

IX. But tho' *Angels* may produce *Material Substances*, yet can they not create them, nor *Spiritual things*. For it implies a *Contradiction*, that a *Creature* should produce any thing out of nothing; *Creation* being an *Operation* to which nothing concurs, save only the *Efficient Cause*; but if an *Angel* could create another, this *Definition* would not hold good; because the produced *Angel* would either totally depend on the Producing *Angel*, or would own *God* also for his *First Cause*. If the first; we must be forc'd to admit something Independent in the *World*, besides *God*, and so *God* would not be the *First Cause*. If the second; since this *Productive Power* in the *Angel* would be subordinate to *God*, the *Effect* would not be attributable to him, but to the *Primary Cause*.

X. You will say, That a *Perfect Efficient* can produce its own like; as *Fire* can produce *Fire*, a *Lion* generate a *Lion*; and that therefore an *Angel* being more perfect than any *Material Thing*, can produce another *Angel*; not indeed by *Generation*, because an *Angel* is a *Simple Being*, not consisting of *Parts*, but by *Creation*.

XI. I Answer, That this *Maxim* of *ARISTOTLE* has no place in *Thinking things*, but only in *Material*, which are subject to *Corruption*, whose *Property* it is to preserve their *Species*, by the multiplication of *Individuals*: Whereas *Angels*, being exempt from *Corruption* and *Materiality*, have no need to preserve their *Species* by *Propagation*.

CHAP. VI.

Of the Number, Distinction, and Subordination of Angels.

It is certain from *Holy Writ*, that there are vast multitudes of *Angels*, which tho' they be sometimes express'd by a certain number, *Dan. 7. 10. Thousands of Thousands ministr'd unto him, and ten Thousand hundred Thousands assisted him. Revel. 5. 11. And the Number of them was, Thousands of Thousands*; yet they cannot be reduc'd to any determinate Number. For since *Great* or *Little* are only *Comparative Terms*, and no Number can be called the greatest, but in comparison with a lesser; the Multitudes of the *Angels* must be compared with some other Multitude; that by the Excess of either we may find out which is the greater.

Hence some are of Opinion, That the number of *Angels* is very great, if compar'd with the number of *Men*, that are, have been; or shall be; since it is not probable that *God* hath left such vast and magnificent Spaces without *Inhabitants*, except only the *Empyrean Heaven*: And because it seems probable to them, that the more *Perfect Beings* should exceed the less *Perfect* and *Ignoble*, in bulk or quantity, if they be *Extended*; and in Number, if *Spiritual*.

This *Argument* would indeed conclude something, in case the *Angels* were *Extended Beings*, and took up place; but being *Intellectual* and devoid of *Matter*, they cannot fill any Space. Nor is the *Reason* that supports this *Argument* of any strength: For if it were generally true, that things more *Perfect* must exceed the less *Perfect* in Number, I know no reason, but that upon the same account it might be concluded, that there must be more *Gods* than one; more *Sans* than *Planets*; more *Pearls* and *Precious Stones*, than *Common Stones*; the first of which is contrary to *Faith*, the second to *Reason*, and the third to *Experience*.

The *TALMUDISTS* reduce the *Angels* to certain Numbers, distributing them into several Companies or Bodies, and assigning to every one of them a set number (as it were) of *Inferiours*; as *Subjects* or *Soldiers*. For according to *R. F. Georgi the Venetian*, of the Order of *St. Francis*, the *Talmudists* distribute the Armies of the *Angels* into *Mazaloth*, *El*, *Legion*, *Ribaton*, *Chirton*, and *Gistera*. *Mazaloth* they say are Twelve, according to the XII Signs of the *Zodiack*. *El* are thirty Bands or Regiments, for every one of those Twelve; and accordingly there are 360 Bands of *Angels*. *Legion* multiplies this Number of 360 by 30; whence doth arise the Number 10800. And this Number they multiply again by Thirty; which makes up *Ribaton*, consisting of Three Hundred and Twenty five Thousand; which multiplyed by Thirty, makes *Chirton*, consisting of Nine Millions, Seven Hundred and twenty Thousand. Which they multiply again by Thirty; the Product whereof is *Gistera*, consisting of Two Hundred and Ninety one Million, and Six Hundred Thousand. The Sum Total of them all being, Three Hundred and One Million, Six Hundred Fifty five Thousand, One Hundred Seventy two, as appears in the subjoyned Table.

12	12 Mazaloth.
30	360 El.
360	10800 Legion.
30	324000 Ribaton.
10800	9720000 Chirton.
30	291600000 Gistera.
324000	301655172 Banns or
30	Regiments of Angels in all,
97200000	
30	
2916000000.	

Whether the *Talmudists* have truly assign'd this number of the *Angels*, cannot be decided by any evident reason: Wherefore we may conclude with *St. Gregory* on the 26. of *Job*, *Humane Reason cannot assign the Number of the Superiour Spirits: because it doth not know the Multitudes of those Invisible Beings.* And a little after, *The Number of the Spirits or Citizens above can only be counted by God, but are Innumerable, as to Men.*

V. As to the Difference of *Intelligences*, the *THO-MISTS* are of Opinion that all of them differ *Specifically*, and that *Intellectual nature* is their *Genus*. Their Reason is, because they make Matter the Principle of *Numerical Distinction*, and therefore suppose that all *Immaterial Things* must differ *Specifically*. But this is a mistake, forasmuch as *Numerical Distinction* doth not arise from matter, but from the *Essence* it self of every thing whereby it is Distinguished from others. According to this Axiom, *Form gives the Being to a thing*, or *Essence* is that whereby a thing is principally known and differenc'd from others. *SCOTUS* therefore calls singular *Essence Hæcceity*. For who will say that two *Modes* in the same *Body*, or two *Perceptions* in the *Soul*, differ *Specifically* only because they are without Matter? Besides, two *Humane Souls* are immaterial, their notion involving nothing besides *Cogitation*; and yet no *Body* ever asserted their *Specific Distinction*: And why may not *Angels* as well differ only *Numerically* under the same *Species*, forasmuch as no Diversity is found in their *Nature*, which consists in *Cogitation*, nor any so great Distinction with Relation to their several *Offices*? For most of them have like *Offices*, and a common Operation. And therefore it is not to be question'd but that many of the *Angels* are of one *Species* and differ only *Numerically*.

VI. Yet for all this, there may be many *Species*, for ought we know amongst the vast number of *Angels*, especially amongst those who are of a Different Order and *Hierarchy*. And this we shall be easily persuaded of by considering the several *Quires* of *Angels*, which seem to differ, as in their *Dignity* and *Offices*, so in their *Essence* also. For these *Functions* being proportioned to their several *Natures*, prove their different condition. Moreover, as the *Beauty* of this visible *World*, consists much in the Different *Species* of *Bodily Things*; so likewise we may with more reason conclude that the *Invisible World* is adorned and Beautified with the Diversity of *Spiritual Natures*. Tho' indeed this is a matter

we cannot absolutely determine, whether the *Angels* differ *Specifically*, or only *Numerically*, and therefore must say with *Damasceus*, *That he only knows this who hath Created them.*

There is without Question an Order and Subordination amongst the *Angels*, which some call a *HIERARCHY*: This is a Greek Word and signifies a *Sacred Rule or Principality*; or a company of *Sacred Princes*, who with some Subordination constitute one *Body*. This *Hierarchy* is commonly said to be twofold, *Ecclesiastical*, or *Heavenly*; the *Ecclesiastical* consists of *Prelats*, *Priests* and *Ministers* of the *Church*; but the *Heavenly Hierarchy*, is the whole Multitude of *Angels*, which is divided into three *Hierarchies*, viz. the superior, which by *FLUD* in his *Philosophy*, is called *EPHONIA*, to which belong the *Seraphims*, *Cherubims* and *Thrones*; the middle-most, or as he will have it, *EPIPHONOMIA*, which contains *Dominations*, *Virtues* and *Powers*; and the Lowest or *EPHONIA*, which consists of *Principalities*, *Archangels* and *Angels*; to all which he assigns several *Offices*. The First of these, because of their most pure *Essence*, he places before *God*, as his *Assisting Ministers*: The second he makes to preside over the *Celestial Spheres*, and to have the Dispensing of their Influences to the inferior *World*: The Third he makes the Superintendents over *Sublunary things*, as being *Spiritual Creatures* diffus'd through *Bodies*, and Destinated to the Quickening and Moving of them, and are therefore call'd *Ministring Spirits*.

But because our forementioned *Doctor* writes very Enigmatically, so as to stand in need of an *Interpreter* rather than a *Reader*, I shall endeavour to give a short Explication of every one of these *Hierarchies*. The First, *Hierarchy* therefore is so called from the Relation they have to *God*, as being, as it were, his *Grandees* and Honourable *Prime Ministers* and *Officers*, who being nearer to *God*, receive his Commands from his Mouth and impart them to *Inferiors*. They who are the highest in this *Hierarchy* are called *Seraphims*, that is, *Burning* or *Flaming*, from the fervour of *Divine Love* Burning in them; being most pure themselves, and greatly purifying others, and wholly aspiring to things that are on high. The Middle Order is that of *Cherubims*, so called from that Transcendent knowledge of all *Divine Mysteries*. The Lowest is that of *Thrones*, who as so many immovable Seats receive the *Rayes* of *Divine Glory*, and without any motion of their own, abandon themselves wholly to *God*.

Dominions, who are the first Order of the second *Hierarchy*, preside over those things that are to be done by *Inferiour Natures*, and by disposing and ordering of them, bear sway in the Government of *Humane Affairs*. *Virtues* execute with a masculine and unshaken Fortitude whatsoever they are charg'd with, as *Dionysius* expresseth it, *Hierarch. cap. 18.* Being always ready and prepared to perform the *Divine will*, Those that are call'd *Powers*, resist *Devils*, and restrain their power, from setting upon *Men*, and from Tempting them beyond their strength.

The Third *Hierarchy* also hath its particular Properties. *Principalities* are destinated to have the superintendence over *Princes* and *Prelats*: *Archangels* over *Kingdoms*, *People* and *Provinces*; and Lastly, *Angels* have the care of particular *Persons*,

VII. The Immense multitude of Angels is distributed into three Hierarchies.

sons, and are as it were Ministers and Messengers between God and Men. Whence it appears that there are Nine Quires or Orders of Angels; Seraphim, Cherubim, Thrones, Dominions, Vertues, Powers, Principalities, Archangels and Angels. The Talmudists also agree in the same Number, tho they call the several Orders by other names.

CHAP. VII.

Whether Angels be in a Place.

I. What Place is, and how many fold.

BEFORE we resolve this Question it will be necessary to Enquire what Place is, and how a thing is said to be somewhere. Place is commonly taken for that space in which things are; and it is twofold, either Internal, which is nothing but the space it self that every Body occupies, and which does not differ from its Extension, but by our manner of conceiving it, in that Extension in a space or place is consider'd in general, and as common to the Air, a Stone, a Book, &c. whereas in Bodies, that are said to be in Space, Extension is only consider'd Individually, and as Inseparable from them. Therefore as a Body consider'd in General consists of three Dimensions; so place is a Space Extended, according to the foresaid Dimensions; so that wheresoever there is a Body there must also of necessity be a Space or Place. External Place is the same with Internal Place, save only in that it denotes over and above the Situation and Order it keeps amongst other Bodies; and is properly nothing else but the surface of a Body, that surrounds another Body, and which with respect to the Body it surrounds, is no more than a Mode, since it cannot be understood without the Conception of a Body.

II. Angels are not in a Place.

THESE things being premis'd, I answer to the Question, that Angels and all Spiritual Substances have no place, neither Internal nor External. Because to be in a Place is the Affection of a Body, and therefore Angels being Incorporeal, and without any Extension, they cannot take up any place; and if they fill no Space, what Situation or Order can they have as to other Bodies? Wherefore Spiritual things can no more be said to be in a place, than they can be said to be of such a Colour, Taste or Smell, which denote Bodily Modes. So that to say that a Thinking Substance can become mensurate to a Space, is the same as if one should assert it to be material.

III. How we are to understand that common saying, that Every thing that is, is somewhere.

YOU will say, if Angels be not contained in any place, then they must be nowhere, which is contrary to that Axiom of Philosophy, that Whatsoever is, is somewhere; and that whatsoever is nowhere doth not exist at all: But Angels do exist, therefore they must be in some place.

IV. Answer.

I answer, if by Nowhere you understand no Space Measurable by Longitude, Latitude, and Profundity, it may be admitted that Intelligences in this sense are nowhere, as being devoid of all Dimensions. But if by nowhere you mean, that Immaterial Beings do not exist at all, this cannot be admitted, forasmuch as in this sense, they are somewhere, that is, they do exist. For it is not necessary that every thing that exists should be comprehended in some Space, this being only proper to Extended Beings or Bodies. Yea, even the whole Universe, containing the Infinite Expansion

of all things, is not comprehended in any Place, but is every where, that is, we can imagin nothing that doth enclose and surround it. And therefore the Category Ubi is only Attributable to the particular Bodies of which the Universe doth consist, not to the Universe it self.

Forasmuch therefore, as the Angels are destitute of all Extension, and do not concur as Parts to the Construction of the Visible World, as particular Bodies do, therefore neither can they be said to be somewhere, that is, to take up some Place. For we are to avoid the perverse Custom of Common Philosophers, who apprehend all things after a Bodily manner; by Attributing some kind of Extension unto them. And yet nothing appears more clearly to our Mind, than that Cogitation, which Constitutes the Nature of an Intellectual Being, is devoid of all Extension, and hath no commerce at all with Matter. Forasmuch therefore as Space in its Conception Involves Extension, it is evident that it cannot be Attributed to Spirits.

If you urge further, that Angels are limited Beings, which cannot be present to all places; and that which is not every where, is comprehended in some Space, and answers to the Determinate part of the Divine Immensity; and that therefore the Angels are in some certain place.

I answer, that this Argument is true in one Sense, and false in another. It is true as to the First Part, that Angels are Finite Beings, as to their Essence and Operation, seeing that they are Creatures, that depend on their Creator both as to their Conservation and Production. Yet can they not be said to be finite as to Quantity, because they are devoid of all Extension, and in that regard are neither Finite nor Infinite, and neither take up all places, nor are shut up in one certain place, forasmuch as to be Extended, and to be in a place, are one and the same thing.

It is true also, as to the Second Part, that the Angels, as all other Creatures, are contained in Gods Immensity; because his Immensity is nothing else, but his Omnipotence, by which he is present to all his Creatures, Producing and Preserving them, as has been explain'd at large in the foregoing part. So that this Omnipresence in God is nothing else but an Extrinsic Denomination springing from Gods Operation, which he works in all Created Things. But it is false that the Angels answer to any part of the Divine Immensity, if the Divine Immensity be conceived under the notion of Infinite Extension, including an Infinite Quantity of real or Virtual Parts: for seeing God is most Simple and free from all manner of Extension, he cannot be Co-extended to the many Parts of the World, nor fill any real or Imaginary Spaces.

Forasmuch therefore as Angels do take up no places, and cannot be said with respect to their Substance to be Here, There, or Every Where; it remains that their presence is only determinable by their Operations. And this seems to follow from the Nature of an Intellectual Creature. For seeing that the Angels are Active Beings, and that the life of Active Existency consists in Operation, we can only say that they are there, where they Operate, viz. in a Body, or about a Body. For since things are said to be somewhere according to their own Proper Nature, Matter being an Unactive Lumpish thing, is Passively Constituted in a Place according

V. Angels being without Extension, cannot be said to be in a Place.

VI. How Angels can be said not to be somewhere, seeing they are Finite.

VII. Answer.

VIII. How the Angels are contained in the Divine Immensity.

IX. The Angels are said to be somewhere by their Operation only.

according to its *Length, Breadth, and Depth*: whereas a *Spirit* is said to be *somewhat Actively*, viz. by that force and Efficacy, whereby it governs and moves the *Body*, and carries it from one *Place* to another; and so is said to be present to that *Body* in which, and about which it immediately works.

X.
The Soul
by its Ope-
ration is
present to
the Body.

Accordingly in the *Fifth Part* of this Institution it will be declar'd that the *Soul* of *Man* is peculiarly present to the *Conarion* or *Glandula Pinealis*, Situate in the midst of the *Brain*; forasmuch as it Operates, and immediately exerts its *Powers* in the same. In like manner the *Divine Immensity* is deduced from his Operation about this *World*, so that before this Operation he could not be stiled *Immense*, no more than he could be called *Creator*, before ever he had Created any thing: Forasmuch as, according to what hath been said before, *Immensity* denotes only a respect between *Created Things*, and *Gods Operation* about them. And upon this account it is that when we pray to *God*, we assign his proper place in *Heaven*, because he there exerts his most wonderful *Operations*, and more Efficaciously manifests his *Power*.

CHAP. VIII.

How Speech is attributable to Angels?

I.
Speech is
twofold.

Notwithstanding that *Angels* are simple Beings, and do not consist of *Soul* and *Body*; yet most *Metaphysicians* Attribute *Speech* to them, whereby they are capable of conversing with one another. For that is not only call'd *Speech*, which is performed by the outward *Organs* of the *Body*, but also that inward speaking of the *Mind*, whereby it thinks or perceives; according to that Expression of the *XIV. Psalm*. *The Fool hath said in his Heart, &c.* and suitable to that way of speaking we so frequently use, when we say to others *What saith your Heart to this or that?* And of this manner of *Speech* *Divines* are to be understood, when they enquire whether *Angels* *Speak*, and make known their *Conceptions* to one another.

II.
It is not ne-
cessary that
Angels
should
speak to one
another.

This *Question* may be resolv'd from the *Third Chapter*; for seeing that *Angels* penetrate each others *Thoughts*, and Voluntary Determinations, they do not seem to need *Speech*, because this is only requisite for *Communication*, and mutual *Society*. For there are four things required to *Speech*. First, that it be free, according to the will of the *Speaker*. Secondly, That it be discovered only according to his intent and liking; so as to reveal secrets to those to whom it is directed, and conceal them from others tho' present. Thirdly, that the *Speaker* be able to excite him whom he is about to speak to, tho' he may be busied about other thoughts. Fourthly, That he that hears may know from whom the *Speech* proceeds.

III.
Angels
cannot
speak ac-
cording to
these Con-
ditions of
Speech.

But how shall the *Speech* of *Angels* be Free, when their *thoughts* are always open to others? and seeing it is not in their *Power* to conceal their *thoughts* from others? How will they be able to chuse their *Auditors*, so as not to open their *Secrets*, but to whom they please, since it is not in their *Power* to hide them, and that their *Perceptions* are as Natural as their *Substance*? Moreover how will they be able to excite their *Auditors* to the understanding of what they have to say, since they have nothing new to manifest to them? Lastly, how

shall the *Auditor* know him that speaks to him, and Distinguish him from others, if he be not call'd upon, and if from his knowledge nothing accrue to him? Wherefore we must conclude that *Angels* do not discourse together after the manner of *Men*; but that they so understand each others *Conceptions*, as that nothing is hid from them. Whence *Divines* tell us that the *Language* of *Angels* is their *Understanding*.

Neither is it any contradiction to this, what the *Scripture* mentions of the *Discourse* and *Speech* of *Angels*, as that of the 7th of the *Revelation*, where an *Angel* is said to call with a loud Voice to the four *Angels*; and in the 6th of *Isaiah* tis said that the *Seraphims* cried one to the other and said, &c. And the *Apostle* saith in the 13 Chapter of the first Epistle to the *Corinthians*, *If I speak with the Tongues of Men and Angels, &c.* because the *Speeches* here spoken of are *Visionary* and only seem'd to be utter'd by the *Angels*. For *Spirits* do not discourse together by an outward Voice formed in the *Air*; neither do they discover their *thoughts* as we do by any outward *Organs*. Therefore these *Speeches* were seemingly heard by the *Prophets*, for their *Illumination*, and that *Posterity* Reading their *Writings*, might be acquainted with those *Mysteries*, and be assur'd of them by their *Testimony*. As to that Expression of the *Apostle*, who Attributes *Tongues* to *Angels*, this must not be understood of those *Internal Speeches* which *Angels* use amongst themselves; but of those which *Angels* in former times used amongst *Men*, to manifest their *Conceptions* unto them, which tho' they were known and understood by *Believers*, yet served only to strike *Unbelievers* with *Wonder*, and *Astonishment*. And that this is the *Genuine Sense* of the *Apostle* in this place, appears from the *Words* immediately following, *and have not Charity, I am become as sounding Brass, or a tinkling Cymbal*; which is only applicable to outward *Speeches*, that is, to *Sounds* and *Voices* utter'd by *Bodily Organs*, which we know cannot be fram'd by *Angels*.

Neither indeed can it be shew'd, how *Angels* *Speak* or *Discourse*, since it may be question'd whether the *signs* wherewith they express their *Thoughts* be *Spiritual* or *Corporeal*. And again, whether those *Signs* be *Natural*, or *Voluntary*. Whether all *Angels* make use of the same *Signs*, or every one of them have *Signs* peculiar to themselves. How it comes to pass, that when one *Angel* speaks, all the rest (without any difference) do not hear his *Speech*? By what Artifice their *Communication* may be hindred? Whether against their Will they perceive the *Speeches* of others; or whether their *Consent* be required to the perception of them? Whether *Angels* can reveal their *Thoughts* to some, and hide them from and impose them upon others? Which things, and many other such like, cannot be attributed to these *Heavenly Spirits*, and therefore prove their *Conversation* to be different from ours.

It remains therefore, if *Speech* be attributable to *Angels*, that the same only belongs to *Superiour Angels*, with respect to such as are *Inferiour*: For seeing that *Speech* is the manifestation of something unknown, if any New thing be discovered to them, it must proceed from the *Superiour Angels*. Wherefore *Divines* admit *Illumination*, which is a kind of *Speech*, to be amongst *Angels*, whereby they

IV.

The Man-
ner how the
Angels
speak is in-
explicable.

VI.
Superior
Angels in-
form the
Inferiour
of things
unknown
to them.

they reveal unknown *Truths*, received from God to one another. And accordingly DAMASCENUS tells us in his *Second Book of Faith*, Chap. 3. *It is evident that all the superiour and higher Angels, do impart their Light and Knowledge to the Inferiour.* So that a more excellent Angel is as a Light to those that are under him, to illuminate them, and communicate new Knowledge to them.

VII.
Sometimes
this Order
is changed.

But tho' this manner of *Illumination* be the most ordinary and best agreeing with the *Angelical Orders*; yet it is not necessary that it should always be after the same way: For without doubt God may manifest a *Mystery* to some *Inferiour Angel*, which by him may afterwards be communicated to the *Superiour*; and accordingly some think it probable, that God communicated his purpose of being *Incaruate*, only to the *Archangel GABRIEL*, who was to carry the *Message* of it to the *Blessed Virgin*; notwithstanding that he belonged to the *Inferiour Hierarchy*. But according to the ordinary course, the *Superiour Angels* Speak, and the *Inferiour* Hear and Listen; the former, as DIONYSIUS tells us, being the *Guides and Teachers* of the latter.

CHAP. IX.

How Angels assume Bodies, and what Actions they exert in them.

I.
Apparitions
of An-
gels have
been very
frequent.

IT cannot be question'd, but that *Angels* and *Devils* do really appear, and take up *Bodies* to make themselves *Visible*; this being a thing abundantly confirm'd by *Profane and Sacred History*. Thus the *Devil*, in the appearance of a *Serpent*, Tempted *Eve*, Gen. 3. *Three Angels* appeared to *Abraham*, Gen. 18. *Two Angels* came to *Sodom*, Gen. 19. The *Angel Gabriel* appeared to the *Blessed Virgin*, and brought her the *Message* of the *Divine Incarnation*. Neither can these *Apparitions* be ascribed to the *Power of Imagination*, or some *Melancholy Humour*, forasmuch as these *Bodies* can be felt, and manifest themselves by *Corporeal qualities*. Seeing therefore we cannot doubt of the *Truth* of these *Bodies*, it remains only to enquire, what kind of *Bodies* are fit for this use, and what *Actions* *Angels* exert in them.

II.
What kind
of Bodies
Angels do
assume.

As to the first of these Enquiries, it seems probable that the *Angels* chiefly assume *Aery Bodies*, which they form by their own *Power*, and adapt them to their *Intention*; so as that from the Different Disposition of the *Parts*, Variety of Colours do arise, and the *Figure* of a *Man* or *Beast* be represented to the *Bebolder*. For these *Bodies* having real *Extension*, and being variously terminated, may according to the various *Reflexion* or *Refraction* of *Light* appear of another *Figure*, *Situation* and *Bulk*, than indeed they are. In this manner, the *Devil*, according to the Relation of *William of Paris* in his last part of the *Universe*, deluded a *Soldier*, by assuming the *Dead Carcase* of a *Beast*, who supposing himself to have enjoyed a *Beautiful Young Woman*, found himself, in the embraces of a loathsome rotten *Carion*: Which sort of *Delusions* are peculiar to *Devils*, who Understanding the *Nature* of *Bodies*, and being skill'd in *Perspectives*, can so order the matter, as to make things appear quite otherwise than they are.

Tho' this be the receiv'd Opinion amongst *Divines*, that *Angels* and *Devils* can assume true *Bodies* in order to their appearing to *Men*; yet I do not see but that they may visibly shew themselves without the taking up of *Bodies*. For seeing *Bodily things*, as MAGNANUS tells us in his *Philosophy of Nature* Cap. 33. have no other *Power of Acting*, than that of moving or resisting *Local Motion*, it will follow, that they appear to our *Senses* either by the *Motions* they impress upon them, or by their resisting of other *Motions*. Wherefore since we understand that a *Spirit* can exert all those *Motions* on our *Senses* which any *Bodily Substance* can, and likewise resist other *Motion* as well as any *Body* whatsoever; we may likewise conceive how a *Spirit* may be perceived by our *Senses* under the *Corporeal Form* of that *Body*, whose *Manner* and *Measure* of *Motion*, or *Resistance* of *Motion*, he shall purpose to imitate. Wherefore an *Angel* in Order to his appearing will not need to make himself a *Body* of such a *Colour*, *Figure* and other *Qualities*, as he intends to appear with; but it will be sufficient, if he only *Refract* and *Reflect* the *Light* in such a *Manner* and *Measure*, as that *Body* would, in whose shape he desires to appear.

III.
Angels can
appear
without
Bodies.

In like Manner when an *Angel* has a mind to make himself *heard*, it will be sufficient, if he only so beat and agitate the *Air*, as that *Sounding Body* would do whose *Sound* or *Voice* he designs to imitate. For by this means the *Agitated Air*, will communicate the *Motion* it hath receiv'd from the *Spirit* to the *Drum* of the *Ear*; and consequently will perceive a *Sound* like to that which the *Body* would have caused. And by this means an *Angel* or *Soul* may at pleasure appear to one *Person*, and hide himself from another, which would be impossible for them to do, after having assum'd an *Aerial Body*; because such a *Body* would indifferently appear to all.

IV.
How an
Angel can
make, a
sound to be
heard.

But forasmuch as both *Angels* and *Devils* do sometimes assume true *Bodies*, as hath been shewn from *Holy Scripture*, we are next to enquire how they are present to these *Bodies*, and what they *Work* in them.

V.
Supposing
Angels to
assume
Bodies,
what they
do with
them, and
work in
them.

Angels are not in *Bodies* after the same Manner as *Souls* are, so as that the *Motions* of the assumed *Body* and *Spirits* should follow the *Voluntary Determinations* of the *Angels*, and that the *Angels* also should be affected by the *Bodies* assumed. For herein doth the Union of *Spiritual* and *Bodily Things* consist, as shall be shewed in the ninth part of this *Institution*. Because it is one thing for a *Spirit* to be present to a *Material thing*, and another to be united to the same: Whenever a *Spirit* is joyned to a *thing*, he is also present with it; but not on the contrary; for a *Spirit* may be present with a *thing* and yet not be united to it. Now that conjunction which is between an *Angel* and his assumed *Body*, is not much unlike that, whereby the *Master* of a *Ship* is present to his *Vessel*, a *Coach-man* to his *Coach*, and a *Rider* to his *Horse*. For as the *Master* of a *Ship* may leave it, and return to it again at his pleasure; so the *Angels* may when they please quit their assumed *Bodies*, and remove into others; which they could not do, in case they were substantially united to them, as *Souls* are to the *Bodies* they animate. And as many *Pilots* may be in the same *Ship*, so more *Angels* or *Devils* than one may be in the same *Body*, as appears from the *Gospel*.

VI.
Angels are
not so inti-
mately
joyn'd to the
Bodies they
assume, as
Souls are
to their
Bodies.

Gospel; but many Souls cannot be joyned to the same Body. The Soul is frequently against its Will united to a Body, and cannot at pleasure be separated from it, whereas an Angel is never unwillingly join'd with the Body it assumes. We conclude therefore that Angels are only accidentally, and as assisting Forms join'd to the Bodies they assume.

VII.
Angels
exert no Vi-
tal Actions
in Bodies.

From what hath been said, it is evident what Angels can perform in the Bodies they take up, and what Actions they exert in them; for it is manifest that they can produce no Vital Operations in them; for tho' they be willing to Eat or Drink, yet are they never troubled with Hunger or Thirst; and tho' they really Eat and Drink, yet have they no Sense of it; and the like may be said of other Corporeal pleasures, which no more affect the Minds of Angels, than that of Eating or Drinking. For all these suppose the union of a Spirit with a Body; and do not so much belong to the Mind as to the Body. For he who resolves for the Love of God to abstain from Eating, hath no will to Eat, because he is otherwise determin'd; and yet frequently feels the gnawing of his Stomach, and dryness of his Throat, and a natural desire to Eat and Drink. And in like Manner Venereal pleasure belongs to the Animal and sensitive life we have here, but not to the life we shall enjoy hereafter: for in the Resurrection, as the Scripture saith, Mankind shall be like the Angels, in Heaven and neither Marry, nor be given in Marriage. Matth. 22. 30.

VIII.
Devils can-
not ge-
nerate.

Whence it appears, that it is altogether irrational what some assert, that MERLIN was begot by a Spirit; that the People called HUNNI were begotten by Satyres on the Bodies of Gothick Witches; or that CORCOTON a Daemon in Hispaniola, was us'd to beget on the Bodies of Women, Births in the shape of Men with Horns on their Heads. These and such like Stories I take to be meer Fables: For seeing that Devils are immaterial, they can neither yield any Matter fit for that purpose of themselves, nor take it from any other Body, forasmuch as it is a part of the Living Body, and the remainder of the best concocted Aliment.

CHAP. X.

Whether there be any Order amongst the Devils; and what kind of Order that is.

I.
Angels have
different
Offices, there
must be
some order
amongst
them.

FORasmuch as the Devils are deputed to different Works, and according to TRITHEMIUS his Opinion, are sent abroad into divers parts of the World, they must of necessity observe some Order, and somewhat imitate the Government that is amongst the Angels of Light. For seeing they perform various Offices, and inhabit the Fire, Air, and Earth, as also the Waters and Bowels of the Earth, and that in perpetual Darkness; it does not appear how they could be kept to their several Tasks and Duties, if there were not some dependence between them, and if they did not derive their Power from one Head. Wherefore, LUCIFER in Holy Writ is called the Devil, because he is the Prince of all the Devils: And accordingly when the Pharisees told our Saviour that he cast out Devils by Beelzebub the Prince of Devils; he replies: If Satan be divided against himself how shall his Kingdom stand? By which Words Christ

himself supposeth that there is a Primacy, and consequently a Government amongst Devils.

The only difficulty here is to explain wherein the mutual subjection of the Devils is founded. Some fix it in the different Perfection of Devils, as supposing them to be endued with Power, according to the Proportion of their Dignity. But this seems to be said without sufficient ground; for there seems to be no Connexion between Natural Perfection, and Command or Moral Præminence, except that the one should necessarily follow from the other; or that one should be the Rule of Manners; neither of which can have place in the Devils; for otherwise an Inferiour Angel would have as many Commanders and Rulers, as there are Angels more perfect than himself, which would be a most miserable State of Slavery, and Incomparably worse than any other.

It seems more Rational to conclude that the Form of their Commonwealth, hath proceeded from themselves, and been established by their mutual consent. For tho' the Devils be exceeding Proud, and each of them hath Ambition enough to aspire to be Governour in chief; yet because they are full of hatred against God and the Envy they bear to Mankind, they suppose they can take no better way to Rob God of his Honour and to destroy the Souls of Men, than by mutually agreeing to submit themselves to a Government settled by Laws. Wherefore the Devils chose Lucifer the first Author of the Rebellion, to be their Prince, as Robbers us'd to do, who having join'd themselves together, choose one from amongst themselves to be their Captain.

But what kind of Government the Devils have amongst themselves, is not easily Determinable, except we assent to them who divide the Devils into three Hierarchies and nine Quires, like the Angels. For so CORNELIUS AGRIPPA in his third Book of Occult Philosophy tells us, that there are Divines, who distribute the Devils into Nine Ranks, as standing in Opposition to the Nine Angelical Orders. Whose Opinion he follows and ranks them so himself.

The First Order of Devils according to Agrippa, are the PSEUDOTHEI, or False Gods, who Usurping the name of God, presume to be worshipt like God, and to have Sacrifices, and Adorations made to them; like that Devil, who said to Christ, All these things will I give thee, if thou wilt fall down and Worship me, shewing him all the Kingdoms of the Earth. And the Prince of these is he who said, I will ascend above the height of the Clouds, and will be like the most High; and who is therefore called Beelzebub, that is, the old God.

The Second Order are the Lying Spirits, such as he was that entred the Prophets of Abab, and was a Lying Spirit in their Mouths. And the Prince of these is the Serpant PYTHON, from whence Apollo is called Pythius, and that Woman Pythionissa, 1 Sam. 28. as also that Other in the Acts of the Apostles, Chap. 16. This sort of Devils make it their business to delude Men by Ambiguous or false Oracles, Divinations, and Predictions.

The Third Order of them are Vessels of Iniquity which are also called Vessels of Wrath. These are the Inventors of all Wicked Arts; such as was the Devil

Devil *THEATUS* mention'd by *Plato*, who taught Men to Game and Play at Dice; for from these all Crimes and Wickedness do proceed, according to that of *Jacob*, Gen. 49. 5. where detelling the cruel Massacre committed by his Sons, *Simeon* and *Levi* upon the *Sichemites*, he saith, *Vessels of Iniquity are in their Habitation*. O my Soul come not thou into their Secrets, &c. The Psalmist calls them *The Vessels of Death*; *Isaiah*, the *Vessels of Fury*; *Jeremy*, the *Vessels of Wrath*, and *Ezekiel* the *Vessels of Murder and Destruction*. Their Prince is *BELIAL*, which signifies without a Yoke or Disobedient and is mentioned by *St. Paul* 1 Cor. 5. 15. where he saith, *What Concord hath Christ with Belial?*

Those of the Fourth Order are called *Avengers of Wickedness*, whose Prince is *ASMODEUS*, the Executioner of Justice.

The Devils next to these are *Juglers*, so called, because they imitate *Miracles*, and assist *Magicians* and *Witches*, seducing the People by their seeming *Miracles*, as the *Serpent* seduced *Eve*. And their Prince is *SATAN*, of whom it is written in the *Revelation*, that he deceives the whole world, working great *Miracles*, and causing Fire to come down from Heaven in the sight of Men, and deceiving the Inhabitants of the Earth by the wonders he doeth.

The Sixth Order are those that are called the Powers of the Air; these are very busy in Thunder and Lightning; they corrupt the Air, and cause the Plague; and of this Number were those, of whom the *Revelation* mentions, that it was given to them to hurt the Earth and the Sea. And their Prince is *MERIZIM*. This is the Noon-Devil, the Burning Spirit, and the Devil that rageth at Noon; whom *St. Paul* in his Epistle to the *Ephesians* calls The Prince of the Powers of the Air, the Spirit that Works in the Children of Disobedience.

The Seventh Rank or Order is that of Furies, the fowers of mischief and Dissension, of Wars and Devastation; whose Prince in the *Revelation* is called *APOLLYON*, and in Hebrew *Abaddon*, that is, the Destroyer.

In the eighth Order are Accusers, whose Prince is called *ASTAROTH*, that is, a Spie; and in Greek *Diabolus*, that is to say a Slanderer; who in the *Revelation* is called the Accuser of the Brethren, who accuseth them before the Face of God, day and night.

The last Order of Devils are those that are called Tempters, or Lysers in wait, who do accompany Men continually to tempt them to Evil, and are therefore called *Bad Angels*. Their Prince is *MAMMON*, that is, Lust or Concupiscense.

And tho' this Ordination of the Devils be no where else to be found but in *Agrippa*, yet is it not therefore to be the less esteemed, seeing that it imitates the Orders of the Good Angels, and is derived and descends from *Lucifer* the Prince of the Apostate Spirits: So that as God hath his Angels, so *Lucifer* hath his Devils.

them; the one General, whereby they are concerned for the whole World; the other particular, whereby they watch over particular Men. Wherefore *NAZIANZEN* in his 6th Poem writeth thus concerning them.

Some with most Awful looks surround the Throne, Ready and Girt to obey the Holy one: Others support the World, and lend their Aid To all the Several Creatures God hath made. Their Care is diverse, as are Gods Commands, These govern Men, and Those Cities and Lands.

Accordingly the Ancients tell us of Universal Angels; every one of which did preside over a whole Nation, and were called the Angels or Genii of such or such a Nation. And of Particular Angels that are singly appointed to take care of this or the other particular Person, and are more particularly called *Genii*, because they superintend the Generation of particular Persons, and as soon as they are born do inseparably assist them. Such an Angel as this is called by *Epictetus* a Keeper, Particular Overseer, a Domestick Spirit, a Proper Custodian, an intimate Cognitor, a Confidential Observer, an individual Abuser, an Inseparable Witness, a Reprover of Misdemeanors, and an Approver of Virtues. *Origen* (saith he in *Arrian*) take it for granted, that every man of us is committed to the care of a certain intelligent and worthy Keeper. Whensoever therefore you shall have shut your Doors upon you, and shut out the Light from you, take heed you do not condemn your selves to be alone; for most certain it is, you are not so, for God is with you, and so likewise is your good Angel.

What the Ancients called *Genii*, the same the Christians call Angels, and do own both their General and special Guardianship. For all Christians hold it for an undoubted Truth, that they have Angels deputed by God to be their Keepers and Companions, to inspect their Actions, to divert Mischief from them, and to take care for their Future Bliss and Happiness. For thus much may be deduced from the Offices of Angels, who, as the Apostle tells us, are *Ministring Spirits*, whose duty chiefly it is to put by the Devils Snares, to exercise Mens Minds to Virtue, to raise up such as are fallen, to suggest good advice, and to present their Prayers and Wishes to Almighty God. Indeed for this very cause they are called Angels, as being a kind of Messengers betwixt God and Men, whom they are to direct as School-masters and Pastors.

In this Angelical superintendency, the Providence of God most clearly appears, forasmuch as he governs and rules these things here below, by Superiour Powers, and Administers changeable things, by such as are Spiritual and unchangeable. For as by the Prudence and Forecast of a Good Emperor (saith *Chrysostom*) all Cities, Towns and Castles, are furnished with sufficient Garrisons against any Hostile Invasion, and all places so provided with Arms, that they may not stand in fear to be laid waste by a Barbarous Incurison: In like manner God, because the Devils with Barbarous and cruel minds are always hovering about us to overthrow our peace and happiness, appoints for our Safeguard the Hosts of his Angels, that by their presence, the stout boldness of the Devils may be repress'd, and the Grace of Peace vouchsafed to us. For Angels are, as it were, the Protectors

IL
The Opinion of the Ancients concerning the Guardianship of Angels.

III.
The same confirm'd by Christians.

IV.
The Angelical care is deducible from the Providence of God.

CHAP. XI.

Of the Care of Angels about Mankind, and the things here below.

I. There is a twofold care of Angels. IT is manifest that God makes use of the Ministry of Angels, in the Ordering of things below; and there seems to be a twofold care in

of Men, specially deputed by God for their Safety: Not as if God were unable to save them; but as a King, who orders his faithful Officers to crush the Delign of his barbarous Enemies, and to Chastize the Insolence of his Subjects.

V.
The same
confirmed
by Scrip-
ture.

Scripture also confirms the same to us: Do not despise one of these Little ones (saith our Saviour,) for their Angels continually behold the Face of my Father which is in Heaven. Wherefore it nearly concerns us always to continue in the Fear of God, as being certain that we have God's Angels about us, who observe all our Thoughts and Actions: And whenever we do that which is good, we cause great Joy to our Angels; whereas, if we do Wickedly, we drive them with grief away from us, and make way for the Devils to come to deceive and ensnare us.

VI.
The Effect
of the
Guardian-
ship of
Angels.

We see therefore that the Assistance of Angels is of great advantage to Men, by procuring them much Good, and by diverting many Evils both from their Souls and Bodies. They greatly assist our Minds, by enlightning our Understanding to perceive Truth, and by exciting our Will to the exercise of Vertue, and to embrace the Good that is offered to us: They also put by many Evils which threaten our Bodies, whether from Natural Causes, or from Free Agents, as from Men that are our Enemies, and from Devils; and prevent them from hurting those, whose Safety they take to heart. Sometimes also they send Sickness and Adversity, to correct Mens Vices, and thereby to reduce them to a sober and sound Mind. Yea, and sometimes may inflict Death also, and that in great Kindness; forasmuch as it may be very pro-

fitable and necessary for some to be taken out of the World, lest being overcome by the Vanities and Lusts of this World, they should run themselves into Perdition.

As there are Special Angels consigned to the Guardianship of Men, so there are others who have care of Cities and Countries committed to them, who, as so many Presidents, or Lords Lieutenants, do watch over them for their Good: And as a whole Nation doth in Dignity far exceed every particular Member of it; so do the Angels, that preside over a whole People, excel those who have the Care only of some particular Person. Now that Nations have their Guardian-Angels allotted them, is most evident from Scripture, Deut. 32. 8. When the Most High divided to the Nations their Inheritance, when he separated the Sons of Adam, he set the Bounds of the People according to the number of his Angels, as the Septuagint expresseth it. Wherefore the Ancient Fathers believed, that the Archangels had the Care committed to them of the Government of the Universal Church. Thus we read that MICHAEL fought with the Dragon, stood up for the defence of the People of Israel, is the Provost of the Church, and assists particular Angels. What is more clear in Scripture, than that GABRIEL was sent with a Message to the Blessed Virgin, about the Salvation of Mankind? and that RAPHAEL was sent to Succour Israel, and to exhort them to the Fear of God? All which are evident Testimonies of the Publick Ministry and Administration of Angels.

VII.
The Super-
intendence
of Angels,
extends it
self also to
Countries
and Cities.

The

The Fourth Part OF THE INSTITUTION OF PHILOSOPHY. VIZ. GENERAL Natural Philosophy.

CHAP. I.

Of the Essence and Certainty of Natural Philosophy.

i.
What Na-
tural Phi-
losophy con-
siders.

HAVING considered the Nature of GOD, and enquired into his Attributes, as far as Human Weakness would permit, and afterwards examin'd the Essence of Angels and Devils, and discovered their Faculties and Operations; PHYSIOLOGY comes next to be considered by us, which contemplates Natural Things, and deduceth their Causes from their first Original. For the Order of Nature seems to require, that having laid down a Supreme and Universal Principle, we should next proceed to the examining of its Effects, that Affections belonging to them may be discovered to us.

ii.
What Na-
tural Phi-
losophy is.

Natural Philosophy therefore, or Physiology, is the Science of Natural Bodies, and their various Affections. And therefore is called Natural Philosophy, because it enquires into the Essence of Material things, and treats of their Properties, Accidents, or Modes: And those are called Natural Things, or Bodies, which are endued with Nature, or that are compounded of Matter and Form, which are the inward Principles of their Activity, Passibility, and Cessation.

iii.
The Word
NATURE
taken in a
threefold
Sense.

The Word NATURE is of various Signification: First, and more strictly, it is taken for the peculiar Disposition of Parts in some particular Body: For when we say, that it is the Nature of Fishes to live in the Water; it is the same as if we said, that the Disposition of their Organs is such, as makes the Element of Water most suitable to them. Secondly, It is taken more largely for the Universal Disposition of all Bodies: And in this

Sense it is nothing else, but the Divine Providence, forasmuch as it governs and directs all things by certain Rules and Laws, accommodated to the Natures of things. Wherefore God is said, to cloath the Lillies of the Field; to send Rain upon the Good and the Bad; and to give Food to all living Creatures; because, that by the Rules by him prescribed, all things conspire to the producing and maintaining such Effects as these. Thirdly, It is taken for the Essence of any thing, with the Attributes belonging to it: Thus we say, that it is the Nature of GOD to be Good, and the Nature of the Soul to Think.

Neither do Natural things differ from those that are made by Art, save only in this, that in the former, how mean soever they be, there appears a far more excellent Artifice, and more exact, con-texture of Parts, than in the latter. Yet this is common to them both, that they are moved from an inward Principle, and perform their Functions by their own Virtue. For a Watch, or Clock is no less moved of it self, by the Figure of its Wheels and Weights, than a Ball of Lead is, whilst it falls down through the Air, towards the Center of the Earth. For every Natural thing is moved by a Motion deriv'd from another, and doth always retain the same, till it be put by by a stronger.

iv.
Natural
things do
not differ
from Arti-
ficial.

Now that Physiology is a Species of Science, and is conversant about things that are True and Necessary; appears from the Demonstrations that are made of Natural things; the Certainty whereof depends on the Stability of the Things that are defined, and supposeth their determinate Essence. For Example, this way of Arguing, Every Extended thing is Divisible; A Body is Extended: Therefore a Body is Divisible, could never be esteem'd a Demonstration, if it were not most certain

v.
Physiology
is a true
Science.

certain that *Extension* enters the Nature of a *Body*, and that *Divisibility*, as a Property, ariseth from it. Now it is notorious, that all certain and necessary Knowledge, is *Science*; since no such can be had, but where the *Effects* are demonstrated by their true *Causes*: And that many such may be had in *Natural Philosophy*, is not to be question'd. For we know that *Matter* is moveable, because it is a *Substance* extended in *Length, Breadth, and Depth*. We know that every *Body* may be carried on from one place to another; because it implies a Contradiction, for one and the same *Body* to be in two places at one and the same time. And innumerable such like, which a *Natural Philosopher* considers as so many unshaken *Truths*, that cannot be gain-said by any Person in his Wits.

VI. If you say, That the Certainty which is required to *Science*, cannot be had in *Natural things*, seeing that *Bodies* and all their *Attributes* are only perceived by the *Senses*; which being liable to Mistake, may represent False things to the *Understanding*: Whence it is that not only *Children*, but also *Men* of Age labour under so many Prejudices, which they being unable to correct, persevere in their *Errors* to their *Lives* end.

VII. I Answer, It is False that *Material things* are known by the *Senses*, as I have shewed by the Example of *Gold*, in the *Second Chapter* of the *First Part* of my *LOGICK*; forasmuch as it continues always the same, tho' it puts on divers *Forms*, and appears variously to the *Senses*. For if we mind well how far our *Senses* reach, and what that precisely is, which they represent to our *Minds*; we shall find, that they give us no such Notions of *Material things*, as we in our *Minds* have of them: And indeed, to speak properly, nothing is convey'd from things without us, by the *Organs* of *Sense*, to our *Minds*, save only some *Bodily motions*, by which the *Idea's* of *Objects* are offer'd to them. For what doth our *Sight* exhibit to us, besides outward *Images*, or our *Hearing*, besides *Voices* and *Words*? So that if we do apprehend any other thing besides those *Pictures* and *Voices*, that is, their Signification; we may be sure the same is offer'd to us, not by our *Senses*, but by those *Idea's* or *Notions* that proceed from our *Thinking Faculty*.

VIII. Wherefore, *Bodily things* are not known by the *Senses*, but by the *Understanding* alone: So that to be sensible of a *Material Substance*, is nothing else, but to have an *Idea* of it, which is not the work of the outward *Senses*, but of *Cogitation*. Neither must this seem strange unto us, seeing that *Certainty* is required to perfect *Knowledge*, which since it cannot be had from the *Senses*, as being subject to *Error*, we must have recourse to the Certainty of the *Understanding* that may correct our *Errors*, and represent the true *Image* of the thing to us.

IX. If you urge further, that there are many Things that cannot be corrected by our *Understanding*, except our *Senses* be first well-disposed, and that our *Mind* borrows its Certainty from them; as appears by a *Stick* standing in *Water*, which be-
cause of the *Refraction* seems to be broken or bent, when indeed it is *strait* or *whole*; because this *Error* is not to be corrected by the *Understanding*, but by the *Touch*: And the same may be said of the other *Senses*.

X. I answer, tho' by our *Touch* we know the *Stick* to be *strait*, yet is not that sufficient to correct the mistake of our *Sight*, but there is need of a *Reason* to persuade us, that in this case we are rather to give credit to the report of our *Touch*, than to that of our *Eye-sight*; which Reason cannot be ascribed to our *Sense*, but to our *Understanding* alone. It remains therefore that the knowledge of *Natural things* depends on our *Cogitation* and that they cannot be perceived by our *Senses* such as indeed they are.

XI. You will object, that *Material Things*, of which *Natural Philosophy* treateth, do not continue in the same *State*, but are subject to various changes, quitting and assuming several *Forms*, which seems to be inconsistent with the Notion of *Science*, which is the knowledge of things certain and *Perpetual*. For what is more common than the *Rise* and *Destruction* of *Bodies*? For all things that consist of *Matter* and *Form* are subject to *Generation* and *Corruption*, and never continue long in the same state and condition.

XII. Nevertheless we must say, that *Natural Philosophy* is indeed a *Science*, because the Nature of a *Science* is not consider'd with respect to the things it treats of, but according to its *Axioms* of an undoubted *Eternal Truth*. For tho' the things which *Physiology* handles, be changeable; yet the *Judgments* we make of them are stable and firm; and consequently the Truth we have of them is *Eternal* and unchangeable. As for example, these are indubitable and constant *Truths*, that all that is *Bodily* is changeable; that every *Mixt Body* is dissoluble, tho' they be of mutable and changeable things. For as the knowledge we have of *Matter* is *Immaterial*; so we may have an immutable *Science* of changeable and corruptible things.

XIII. Forasmuch as every *Science* hath a *Subject*, about which it is conversant, and to which, whatsoever is handled in the same may be attributed either as *Principles, Parts* or *Affections*; we say that the *Material Subjects* of *Physiology*, are natural things; and that *Magnitudes, Figures, Situation, Motion* and *Rest* are the *Formal Subject* of it; as under which, *Bodily things* are consider'd, and from whence they derive their force and *Virtue*, as shall be said in the 10th Chapter. Wherefore if a *Natural Philosopher* consider nothing in *Matter* besides these *Divisions, Figures* and *Motions*, and admit nothing for *Truth* concerning them, which is not evidently deducible from common Notions, whose *Truth* is unquestionable, it is altogether manifest, that no other *Principles* are to be lookt for in *Natural Philosophy*, than in *Geometry* or *abstract Mathematicks*: and consequently that we may have as well Demonstrations of *Natural Things*, as of *Mathematical*.

XIV. But before I proceed any further, I must acquaint the Reader, that I undertake nothing here but the explication of *Natural Things*; and that my only design is to explain them by their *Effects*, and *Causes*, that so I may contain my self within the Bounds of the *Science* I treat of. Wherefore I openly profess, that I consider *Natural Things*, in their *Natural State*, and that my purpose is not in the least to treat of them, as they pass the Bounds of *Nature*, and are put in a *Supernatural condition*. For it would be great Rashness in me to set Bounds to the *Divine Omnipotence*, by pointing out how far

far it can go. But rather as I acknowledge God to be the Author of the World and of all things, so likewise I own that Infinite Things may be produced by him, which the mind of Man cannot reach in the least.

XV.
Natural
Philosophy
is either
General or
Special.

Natural Things are considered two manner of ways in Physiology, viz. either Generally or Specially; and accordingly Natural Philosophy is Distinguished into that which is General, and that which is Special or Particular. General Physiology is, that which considers a Body or Matter in General, that is, its Nature, Principles, General Affections and Differences. Special or Particular Physiology is that, which considers Matter as distinguished into Species; and doth more particularly explain the Properties, Differences and Changes of those several Species. Wherefore we are to begin with the most simple Principles of Natural Things, and from them proceed to the Bodies themselves, that are made up of them.

CHAP. II.

The Existence of Material Things Proved.

I.
We may
question the
Existence of
Bodily
things.

FORasmuch as it is lawful to doubt of every thing, whether or no it do Exist, as long as its nature is not clearly known to us; we may also question whether Material Substances be, beside our Cogitation, and if they be, by what Argument this may be proved: As to which thing every one will be able with great ease to satisfy himself in this matter, only by giving heed to the Conception we have of Bodily Things.

II.
The Notion
of a Mate-
rial thing
frequently
occurs to
us.

No Philosopher ever deny'd that we have the Notion of Material Things; yea, if we thoroughly examine their Nature, we shall find many Properties in them, which would not agree to them, if they had not some Nature. For we can Demonstrate of an Extended Being, that it is Moveable, Divisible, Impenetrable, &c. For since to be extended is nothing else but to have distinct Parts, it cannot happen by the Power of Nature, that the parts of Matter should take up the same place.

III.
God can do
whatsoever
can be
clearly
known, or
apprehend-
ed by us.

Moreover, we know God to be Omnipotent, and that he can do whatsoever can be clearly and distinctly known by us. Yea, if we will reason aright, we must say, that nothing is impossible, but because it is inconsistent with our clear and distinct perception: But we do clearly and distinctly know Matter to be something extended in Length, Breadth and Depth: Therefore Matter must at least be producible by God.

IV.
The Actual
Existence of
Bodily
things
proved.

Nor will it be difficult to prove that this Material Substance doth exist actually. For tho' our Senses be apt to deceive us; yet we cannot doubt of all the things they represent to us. Because we daily experience and find in our selves many Ideas or Species of Natural things, which must proceed from some things or other without us, that are the Causes of such Ideas. For it doth not depend on our Wills, that we perceive by our Senses one Substance more than another; but that difference proceeds from the Objects, which produce such a Sensation in us. For oftentimes these Species occur to us without our heeding it; and before that we think of them by any reflex Cogitation. Wherefore we must conclude that these Ideas proceed from things, which consequently must exist in Nature.

Lastly, there is no Man who doth not perceive himself to be endued with an Imaginative Faculty, in that he doth almost every moment conceive so various and different things; now the Imaginative Faculty considers Bodies as present, and is altogether conversant about Bodies; wherefore it is necessary in order to its perfection that Material Things should exist.

If you object, that nothing of certainty can be gather'd from the Senses, forasmuch as they do frequently deceive us. For we find by experience that things are represented by them otherwise than they are, as when a Square Steeple appears round to us at a distance; or when a great Brass Ball at the top of a high Steeple, shews like a little Apple to our Sight.

I answer, that these Errors do not destroy the Truth of Material Things, tho' our Senses deceive us in their representing of them. For it may happen that that which I see with my Eyes, is quite another thing than I imagin it to be; yet for all that it cannot be, but that which does appear to me must be something Material, which is sufficient to prove the Existence of Matter; because the variety of Figures does not take away the Subject, but rather doth manifest it, and forceth us to confess, that those things that appear to us under divers Figures are something that is Material or Corporeal.

Neither do those things that are within us, less evidence this Truth than those that are without us: For if we give heed to the Ideas of things in our Mind, we shall find that besides the notions of Intimate Consciousness, Perception, Judgment, and Affections, we meet with others that consist of Extended Parts, diversified by Length, Breadth and Depth. Moreover, besides these, we experience many Motions in our selves, as Hunger, Thirst, Pain, which do not belong to our Soul, forasmuch as it is a Thinking Being; for the Soul of Man being Immaterial is incapable of any of these, and only perceives them as she is united to a Material Substance. For Pain doth not touch our Mind, save only so far, as it is joyn'd to the Body; neither can it be vexed with Hunger, or Thirst, save only so far as it is link'd to the Stomach and Throat, the one whereof is pinch'd with a Vellication, and the other with Drought. So that it cannot be doubted but that there are many Ideas of Natural Things in us which are not fram'd by our selves, but come to us from abroad, and present themselves to our Imagination.

For as the Philosopher discourseth in the last Part of his Principles, Sect. 1. We may enquire concerning the thing which is represented to us, whether it be God, or something distinct from him: But because we feel, or rather by Motions impress'd upon our Senses, do clearly and distinctly perceive a certain matter extended in Length, Breadth and Depth, whose various parts have diverse Figures, and are rost with several Motions; and are the cause of Diversel Sensations in us, as of Colours, Smells, Pains, &c. If God did immediately by himself represent the Idea of Matter to our Minds; or if he should cause the Idea thereof to be represented to us, by any thing wherein there was nothing of Extension, Figure or Motion, this would be to impose upon us. For we clearly understand Extended Matter, as a thing altogether distinct both from God and from our selves, that is, our Minds; and

V.
Tho' the
Senses de-
ceive us in
the manner
of their re-
presenting
things to
us; yet
not with
respect to
the sub-
stance of
things.
VI.
Answer.

VII.
The Moti-
ons we find
in our
selves prove
us to be
Corporeal.

VIII.
If there
were no ma-
terial
things
without us,
God might
be thought
to impose
upon us.

we clearly seem to perceive that the said *Idea* proceeds from things plac'd without us: Now it is utterly repugnant to the *Nature* of *God* to impose upon us. And therefore we must peremptorily conclude that there is really *Existing* such a thing as is extended in *Length*, *Breadth* and *Depth*, and hath all those *Properties*, which we do clearly perceive do agree to such a *Being*. And this is that thing which we call *Body* or *Matter*.

IX. But forasmuch as every thing is best known by its *Essence*, *Properties* and *Affections* or *Accidences*, to the end we may have a more perfect knowledge of *Matter*, whose *Existence* we have just now demonstrated, it must be our business to prove, wherein its *Nature* doth consist, what are its *Properties* and what *Accidences* it is capable of. Accordingly we will first enquire what it is that doth constitute *Matter*, and next what those things are that do inseparably accompany it, and lastly the *Accidences* that happen to it.

CHAP. III.

Of the Nature and Constitution of Matter.

I. **M**atter is a *Body*, inasmuch as it is a *Body* or a *Substance* extended in *Length*, *Breadth* and *Depth*: Wherefore a *Material* and a *Bodily* thing are *Synonymous Terms*, and do not differ, save by our *Mode* of considering them. That which consider'd absolutely is call'd a *Body*; the same with regard to that which is made of it, is call'd *Matter*: As for example, this extended *Mass*, consider'd as something undivided, and indistinguish'd, is a *Body*; but if referr'd to those distinct *Bodies* that are made out of it, it is called their *Matter*.

II. This is that *First Matter* about which there are so many Squabblings in the *Peripatetick School*; and is nothing else, but an inadequate Conception of a *Body*, as it may be conceiv'd by us without any *Figure*, *Hardness*, *Softness*, *Colour*, or any other Modifications, and only as Extended, and consisting of three *Dimensions*. For the further Explication of this *Notion*, and that the agreement of the *Cartesians* and *Peripateticks* in this matter may appear, I shall add these following Propositions.

III. The *First Proposition*: The *First matter* is without form: For in this, the *Notion* of *Extension* is abstracted from all Modifications, that belong to the *Essence* of a *Body*.

IV. The *Second*: The *Matter* of all things is the same; for all *Bodies* agree in this first or Primary *Attribute* of a *Body*, viz. *Extension*, neither is there any Distinction between them with relation to the *Matter*.

V. The *Third*: Every thing may be made of every thing; or, according to the *Peripateticks*, *Matter* is capable of all *Forms*: For since all *Bodies* agree in *Extension*, all their difference must be from their various Modifications; if therefore there be an *Efficient Cause* sufficient to alter these *Modes*, it may make every thing of Every thing. On this Proposition are grounded all those varieties which are observed in *Bodies*.

VI. The *Fourth*: A *Body* as such, or the *First Matter*, is *Ingenerable* and *Incorruptible*: that is to say, there is no new *Substance* created; neither is the

least part of *Matter* annihilated; for only the *Modes* are changed, in all Alterations.

Physical Matter therefore, or a *Natural Body*, is a *Substance* Extended in *Length*, *Breadth* and *Depth*; neither can any thing else be represented to the *Imagination* by the name of *Matter*: For *Extension*, as hath been said, is that Primary, *Immediate*, and *Radical Attribute*, which is conceiv'd or apprehended in every *Body*, and which in all alterations continues the same, nor can it be destroyed, but by Annihilation of the *Body*. So that we must stand to it as an undoubted Truth, that *Extension* is identified, that is, is one and the same thing with *Matter*, so that how much soever is taken from *Quantity*, so much is taken away from the *Body*; and on the other hand, whatsoever is taken from *Body*, the same is taken from the *Quantity* of it.

Most men I know are of *Opinion*, that herein we differ from *Aristotle*, who in his *Metaphysics* tells us, that *Matter* of it self is neither *Quid* (something) nor *Quantum* (of any Bulk or Quantity) nor any other thing of all those, whereby a *Being* is determin'd. From which words they argue that *Aristotle* supposed *Matter* to be devoid of all *Extension*, yea that it did not exist in the nature of things.

To which I answer, that *Aristotle* indeed makes a distinction between *Extension* and *Quantity*, which we also freely admit, because *Matter* may be conceived without *Quantity*. For he that Measures a piece of *Land*, immediately conceives the *Extension* of it, but doth not know the *Quantity* of it, till after he hath measur'd it. Indeed *Quantity* is nothing else but a certain mode of *Extension*, or some Measure of it, by which we answer him, who demands what the *Quantity* or *Bigness* of a *Body* is. And so *Quantity* is an *Attribute* modally distinct from *Extension*. And in this *Sense* it is not repugnant to say, that *Matter* is an extended *Substance*, and yet that it is nothing of all those things which *Aristotle* in the foresaid place removes from it; forasmuch as they cannot be understood but of *Matter* determin'd by some particular *Form*. Thus we cannot say that *Matter* Universally taken, and as consider'd at first view, is either *Hot* or *Cold*; that it is of such a determinate Measure, or that it is some particular thing, as *Wood*, *Marble*, *Gold*, &c. much after the same manner as when we consider a living *Sensitive Creature* in General, we cannot say that it is a *Horse* more than a *Lion* or any other particular *Species*.

Neither do those argue at any better rate, who distinguish *Extension* from *Matter*, and consider it only as a *Mode* of it: As for example, whilst they mind the *Extension* of a *Table*, they will have the *Extension* to be the *Mode*, and the *Table*, the *Substance* whose *Mode* it is: For these talk as absurdly, as if one hearing another discoursing of the *City* of *Rome*, should imagine these to be two different things, whereof the one should be the *Mode* and the other the *Substance*; or as if one should go about to distinguish *Humanity* from *Man*. For as *Humanity*, or the *Nature* of *Man*, doth not differ from *Man* generally consider'd, but only as an Abstract and Concrete, so neither doth *Extension* differ from a *Body* in a general acception.

Those therefore who deny that *Extension* constitutes the *Nature* or *Essence* of *Matter*, will never be able distinctly to explain what they mean by the

VII. What we are to understand by the word Matter.

VIII. Aristotle doth not oppose this Doctrine in his Metaphysics.

IX. Extension is not the Mode of a Body.

X. Why the Natural Philosophy of the Schools is so barren.

Word *Matter*, nor wherein its *Essence* doth consist: Yea, they lay that down for a *Principle*, from which it is impossible for them to deduce any *Consequence*, which may illustrate the *Mind* of Man, or be of use towards the discovery of any *Truth*; and therefore they must not wonder to find their *Physiology* so barren as it is, and that they have not been able hitherto to explain the least product of *Nature* by means of it.

XI. *Whether there be no more Matter in a Vessel fill'd with Gold, than in one fill'd with Air.*

But they who estimate the *Properties* of *Matter* by their *Senses*, and by them measure the *Essences* of things, argue thus against this Opinion. If a *Bodily Substance* were something indistinct from *Extension*, it would follow, that wherever there was found some *Proportion* of *Matter*, there would also be the same of *Quantity*: But this is found to be false in two *Vessels* of the same bigness, forasmuch as more *Matter* is found to be in that which is fill'd with *Gold*, than in the other which is only fill'd with *Air* or *Water*. Therefore *Quantity* is not always proportionate to the *Body*, and consequently differs from it.

XII. *Answer.* I answer, that there is no more *Matter* in the *Vessel* that is fill'd with *Gold*, than in the other that contains *Water* or *Air*, tho' indeed there be more *Hardness* and *Weight* in the one than the other: For the *Essence* of *Matter* doth not consist in *Hardness* or *Weight*, or any other *Qualities*; for *Fire* that is subtil, and melted *Wax* that hath lost its *hardness*, is never a whit less a *Body*, than the heaviest *Metal*; and therefore *Matter* precisely consists in this, that it is extended in *Length*, *Breadth* and *Depth*, which is found to be equal in both *Vessels*.

XIII. *The Nature of a Body doth not consist in Hardness.* Conclude we therefore, that the *Nature* of *Material* things doth not consist in *Weight*, *Hardness*, *Colour*, or the like, but in this only that they are *Extended Beings*. For as to *Hardness* we can apprehend nothing else of it by our *Sense*, than that the *Parts* of hard *Bodies* resist the *Motion* of our *Hands*, when they run against them; for if as oft as our *Hands* are mov'd towards any place, all the *Bodies* that are there should give way, and remove thence with the same *swiftness*, as our *Hands* advance, we should never feel any *Hardness*. Neither can it be conceived, that the *Bodies* which thus remove or give way, should therefore lose the *Nature* of *Bodies*: wherefore the *Essence* of *Material Things* doth not consist in *Hardness*.

XIV. *Nor in Figure, Weight, Colour, &c.* And in like manner it may be made out, that *Weight*, *Colour*, and other such *Qualities*, which by the *Senses* are perceiv'd in *Matter*, may be taken away from it self, remaining whole as before: For suppose the *Hardness* of *Ice* melted into *Water*, to be vanished; its *Figure* also to be quite changed; suppose also that *Water* to be rarified into *Vapors*, and having quit its *Bulk* and *Heaviness* to disappear from our *Eyes*, by its extreme *Tenuity* and *Thinness*; yet it is evident that the *Bodily Quantity* or *Extension*, which is the *Seat* and *Subject* of all these mutations, does remain entire and untoucht, and altogether inseparable from the *Ice*, the *Water* and *Vapors*.

XV. *An Object on that Matter ought to be Defined by some Relation to the Senses.* It may be you will say, that tho' a *Body* be not bound to one *Figure*, and may be deprived of a *Cubical*, *Triangular* or *Spherical Figure*, yet must it still have some *Figure* or other. In like manner tho' a *Body* be not necessarily either *Soft* or *Hard*, *Hot* or *Cold*, yet it is necessary that a *Body* should be sensible, or as *Lucretius* expresseth it, *Tangible*.

Besides a Body, as we see, Nothing can Touch, or Touched be.

To which I answer, *First*, that *Sensibility* is only one of the *Properties* of a *Body*, and not the whole nature of it; since a *Body* may really exist, tho' there should be no Men to whose *Senses* it might offer it self to be perceived; as we know that *Matter* was created before there were any *Senses* made. Wherefore there seems to be no absolute *Necessity* that every *Body* should be sensible. On the contrary, we find that there is no *Body*, which may not become insensible, by being divided into so minute parts, as not to be able to move our *Nerves*, especially if those parts be also swiftly moved.

I answer *Secondly*, that a *Power* to affect the *Senses*, presupposeth something that is extended, and is no more than a *Respect*, and *Extrinsic Denomination*, which must be grounded in some *Internal* or absolute *Attribute*.

Extension therefore is that alone which constitutes the *Nature* of a *Body*, as agreeing to all, only, and always, to them, so that nothing can be perceived in a *Body* before it. For it agrees to every *Body*, to *Earthly* as well as to *Heavenly*, to the *Sun*, *Fire*, *Air*, as well as to *Wood*, *Stone*, &c. It belongs only to a *Body*, because no *Intellectual Substance* is *Extended* and *Divisible*. And it agrees always to a *Body*; because tho' all other *Attributes* be taken from it, and be changed, yet the *Extension* continues as long as the *Body* doth. Besides, nothing can be conceived in *Matter* before *Extension*; for tho' *Matter* be *Divisible* into *Parts*, yet that is not the first affection we perceive therein; for therefore only a thing is *Divisible* because it is extended.

Some are of opinion that *Quantity* may be increased, without any increase of the *Matter*: Thus in *Rarefaction* the *Quantity* seems to be augmented, tho' the *Substance* continue the same it was; and this they endeavour to prove by a *Pot of Water* on the *Fire* that boils over; at which time they suppose the *Water* to take up more place than it did before; now it cannot take up a larger place, without a greater degree of *Extension*.

I answer, that *Rarefaction* is not performed by an addition of *Quantity*, but by the entrance of other little *Bodies* from abroad; so that those *Bodies* are said to be rarefied, whose *Pores* being opened are filled with the *Air*, or some other *Subtil Matter* entering into them; and they become close or compact again, when by the expulsion of those *Adventitious Particles*, those *Spaces* are narrowed again, and the parts come closer together. For certain it is, that nothing can be increased in *Quantity*, but that at the same time its *Extension* must be increased also. Of which I shall treat more at large when I shall have occasion to speak of *Rarefaction*.

But you will object, that *Space* is conceiv'd to be something extended in *Length*, *Breadth* and *Depth*: Yet *Space* is not a *Body*; therefore the *Essence* of a *Body* doth not consist in *Extension*. The *Minor* is proved, for that if *Space* were a *Body*, then one *Body* would be in another.

I answer, It is false to say that *Space* is not a *Body*; because the same *Extension* which constitutes the nature of a *Body*, doth also constitute that

XVI. *The First Answer.*

XVII. *The Second Answer.*

XVIII. *Extension only belongs to the Essence of a Body.*

XIX. *That Quantity seems to be increased in Rarefaction.*

XX. *Rarefaction is performed, by the introduction of another Matter.*

XXI. *An Object on from the Nature of Space.*

XXII. *Answer.*

that of *Space*. And therefore to say that a *Body* takes up such a *Space*, is no more than to say, that it is so great a part of the *World*; because *Bodies* bring their *Spaces* along with them, and when they remove, carry them away with them. And when *Bodies* are said to leave their *Spaces*, it is the same as to say that they quit the *Magnitude*, *Figure* and *Situation* they had amongst other *Bodies*. Wherefore the *Extension* of *Space* doth not differ really, from the *Extension* of a *Body*, and therefore we must conclude every *Space* to be corporeal.

XXIII. And whereas some say that *God* occupies or takes up all places of the *World*, as being *Infinite*, *Immen-*
Tho' God be
immense or
infinite, yet
he hath no
quantity.
XXIII.
Tho' God be
immense or
infinite, yet
he hath no
quantity.
 mense and *Omnipresent*, &c. which cannot be conceived without some *Extension*; this is an objection of no moment. For tho' *God* be *Omnipresent*, yet this doth not prove him to be extended; because by an *Extended Being* all *Men* understand something that is *Imaginable*, of a certain *Figure* and *Magnitude*; whose parts are separate from each other, so that one of them cannot be in the place of the other; which cannot agree to *God*, or any *Spiritual Substance*, as being imperceptible to the *Imagination*, and apprehended by the *Intellect* only. When we say that *God* is extended through all the *World*, this is not to be understood of the *Extension* of *Substance*, but of the *Extension* of *Power*, so that the meaning only is, that *God* can exercise his *Power*, sometimes on a greater, and other times on a less part of *Matter*. For if there were no *Bodies*, we could not conceive a *Space*, to which *God* should be co-extended.

XXIV. Wherefore with our *Philosopher* I profess my
A Natural
Body is the
same with
a Mathe-
matical
Body.
 self to own no other *Matter* of *Bodily things*, than that which is altogether *Divisible*, *Figurable* and *Moveable*, which *Geometricians* call *Quantity*, and which they make the object of their *Demonstrations*; and that I consider nothing in it, besides those *Divisions*, *Figures* and *Motions* which are the properties of it. And tho' such a *Body* as I have here described, be by others called *Mathematical*, yet I take it here in this *General Physiology* for a true and *Real Body*. Indeed *Natural Philosophy* is one of the parts of the *Mathematicks*, and has the same relation thereto, as *Metaphysics* have to the other *Disciplines*; the only Difference between them is, that the *Mathematicks* consider *Magnitudes* and *Figures* abstractedly, without being solicitous whether they be such indeed, or only can or may be so. But *Physiology* considers the same as inherent in *Matter*, and as she finds them in the several *Bodies* that are in the *Universe*. Now this *Abstraction* doth not at all hinder, but that *Physical* or *Natural Matter* may be the same with the *Geometrical*, because the *Species* is not really distinct from its *Genus*.

CHAP. IV.

Of the Proprieties of Extended Substance,
 viz. Mensurability, Divisibility and Im-
 penetrability.

I. Here are three Properties which accompany
 an Extended Substance or Quantity, viz.
 Mensurability, Divisibility and Impenetrability.
 Mensurability is an aptitude in a Body, whereby

it may be apply'd or conform'd to a certain measure. the Proper-
 Divisibility is that disposition of a Body where- ties of an
 by it is conceiv'd to have Parts into which Extended
 it may actually, or by thought, be divided. Substance.
 Lastly, Impenetrability is the distinction of one
 Extended Being from another, by which the
 Extension of one thing is different from that of
 another; so that two things Extended cannot be in
 the same place, but must of Necessity exclude each
 other.

That a Bodily Substance is Mensurable and Di-
 visible, may be easily gathered from what goes be-
 fore; for since it hath a threefold Dimension, Length,
 Breadth and Depth, it must also admit a threefold
 Measure, by which its Magnitude may be deter-
 min'd. Its Divisibility also may be gather'd with
 the same evidence from its Extension, forasmuch
 as it hath Parts placed besides one another, so that
 we may easily conceive them to be separable, in
 which the very Essence of Division consists. But
 because many, who follow DEMOCRITUS, are
 of opinion, that there may be Indivisible Bodies
 out of which all other things are made, it will be
 worth our enquiry, whether the parts that consti-
 tute Matter, be Indivisible, or such as admit of
 further Division.

To which I answer, that Matter is not com-
 pounded of Indivisibles, that is, of parts that can-
 not be divided into others. This is the opinion of
 most Philosophers, and the reason is this, because
 the Essence of Matter is to have parts that are ex-
 tended; and whatsoever is extended, is Divisible.
 For it cannot be conceived that a thing should be
 Extended, and yet not be Divisible; because Ex-
 tension is nothing else, but an answerableness to
 divers points of Place, and such a disposition
 wherein one part is distant from another, not by
 actual separation, but by an aptitude to be sepa-
 rated, which is sufficient to make one thing not
 to be another.

Moreover, Beings are not to be multiplied with-
 out necessity; now there is none that forceth us to
 have recourse to Indivisibles: For Points are not
 the Parts of a Line, but smaller Lines; neither
 are the Parts of a Surface Indivisible Lines, but
 smaller Surfaces; neither are the Parts of a Body
 Atoms, or Indivisibles, but Particles indefinitely
 lesser, or Divisible without end. For in things
 extended we can never come to the very least Part,
 because as long as it is extended, it cannot but be
 conceiv'd Divisible. Whence proceeds that Axiom,
 that no Quantity or Magnitude can be made of that
 which is not Quantitative. If you say that the
 Terms or extremes of Magnitude cannot be ex-
 plain'd without them; I answer, that every Ex-
 tended Being is sufficiently terminated by the nega-
 tion of any further Extension: Nor do I see, what
 can be more requir'd to the Termination of a thing,
 than that it is no further extended. If it be said
 that they are necessary to joyn the Parts of Matter.
 I answer that neither are they necessary upon that
 account, because the Parts of Matter sufficiently
 hang together without standing in need of a third
 to link them together.

You will Object, that there are some Particles in
 Bodies so small, that they cannot be divided; and
 without question there may be such, as Atoms,
 and the like, which can by no human artifice be
 made less than they are; and yet no Body can
 deny

II.
 From the
 Extension of
 Matter we
 may easily
 infer its
 Divisibi-
 lity.

III.
 Every Bo-
 dy is Divi-
 sible.

IV.
 There are
 no Indivi-
 sible Bodies.

V.
 An Argu-
 ment to
 prove
 Atoms.

deny these to be *Corporeal Substances*; therefore it cannot be said that a *Body* is divisible into parts that are always further Divisible.

VI. I say it is Impossible that any *Body* should have any parts so small as to be Indivisible, because the least part or *Atome* of a *Body* is extended, and therefore cannot be Indivisible. For *Bodies* as such are Extended, without which they cannot be conceived. For suppose an *Atome* lying on a *Plain*, or three *Atomes* join'd together on a *Plain*, they must be suppos'd to have *Sides*, whereby they touch both themselves and the *Plain*, which is their Extension.

VII. *Matter* therefore is Indefinitely Divisible; that is, the *Mind* of *Man* in the Division of *Matter* can never come to a *Term* where it is stop't from proceeding further; for the least *Particle* will always be extended, and whatsoever is extended must therefore be conceiv'd to have distinct *Parts*, and what is conceiv'd to have such *Parts*, must be conceiv'd Divisible; especially if we consider that *God* can do whatsoever we do clearly and distinctly conceive. And tho' *God*, it may be, will have it so, that some *Atomes* should not be actually divided by us, yet we must not say that he hath deprived them of the Power to be divided; for we clearly understand that they can be divided by *God*, as long as we suppose them to be Extended. Therefore Indivisibles cannot enter the Composition of a *Body*; forasmuch as nothing is found in a *Body*, that doth not consist of *Length*, *Breadth* and *Depth*.

VIII. But tho' the *Parts* of *Matter* be always Divisible, so as that we can never come to the very least of them; yet doth it not follow therefore that the *Parts* of *Matter* are Infinite, but only Indefinite. For it is one thing to say a thing is Infinitely Extended; and another, to say it is only Indefinitely so. That is Infinite in which there are no Bounds at all, and so *God* alone is Infinite: Whereas those things which in some respect only have no End, are better called Indefinite, than Infinite; such as *Matter* is, which divide it never so much, will still be further divisible. And herein *Magnitude* differs from *Multitude*, because in the latter we come by division to a *Unity* or Indivisible; whereas in the Division of the former, we may still go on, and divide for ever. Because a *Body* cannot be divided into so many *Parts*, but that every one of them will still be capable of a further Division; and therefore these parts are said to be Indefinitely extended. This will appear more clearly by an *Argument* taken from *Geometry*, because in that *Science* it can be demonstrated, that there are some *Magnitudes* which have no common Measure, and therefore are called Incommensurable, as are the *Diagonal line*, and the sides of a *Quadrangle* or *Square Figure*.

IX. Two Quantities are said to be Commensurable, when we can find a Third, which is a Part of both the one and the other, that is to say, which measures them both. Thus a *Pace* and a *Rod* are two Commensurable Quantities, because we can name a third Quantity, viz. half a Foot, which will measure both a *Pace* and a *Rod*; for the half Foot taken five times, will be equal to a *Pace*, and the same Measure taken twelve times will be equal to a *Rod*.

But if no such third Quantity can be found to measure them both, then those Quantities are called Incommensurable. Supposing therefore the Figure A B C D to be a *Quadrangle*, it is manifest by Geometrical Demonstration that the side of A B is in Commensurable with the Diameter or Diagonal A B.

Divide we then in our *Mind* the Line A B into a thousand equal Parts, and every one of those again into a thousand more, and these last again into a thousand other equal Parts. This Division may be continued for a hundred years, and yet shall we never be able to come to Parts so small, that we can say that the Line A C contains a certain and determinate number of them. Which could never happen so, if Extension could not be Indefinitely prolonged. For after the Division, by Example of the Line A B into the least Parts into which Extension could be divided, it would necessarily follow that the Line A C contains a certain and determinate number of them. Wherefore we must conclude that every Extension, or determinate Portion of *Matter* is Indefinitely Divisible.

It may be oppos'd to this Demonstration, that in case all *Bodies* were Indefinitely Extended, it would follow that two *Bodies* of unequal Magnitude, would have an equal number of Parts. Yea, moreover if it be granted that one Part of a *Body* be Indefinitely Divisible, there will be as great a Divisibility in one part as in the whole; For Example, in a grain of Barley as in the whole Field wherein it grew. But this seems very absurd, that there should be as much divisibility in the least part of *Matter* as in the vastest quantity; wherefore Indefinite Partition cannot agree to Extension.

To which I answer in the first place, that they are very much mistaken who attribute Equality or Inequality to a thing Indefinite, these being the Properties of Finite things only. For how can these things be call'd Equal or Unequal, which are Indefinitely divisible, and to the least part of which we can never come? Those things only can be call'd Equal or Unequal, which we can comprehend, and compare together; but not those which are Indefinitely Divisible, and which our *Mind* can neither apprehend, nor compare together.

Secondly, supposing two unequal Bodies, should be divided into an equal number of Parts, yet would it not follow thence that those two Bodies were Equal; because the Parts of one Body, would proportionably be greater than the Parts of the other Body, and therefore the Divisibility of one Grain would not be so great, as that of the whole Field wherein it grew, tho' it be Divisible into as many parts.

Neither is a sufficient argument against this, that some say they cannot comprehend how the least Body should be Indefinitely Divisible; for who knows not that there is a vast number of things which cannot be comprehended by the Imagination? The famous ROHAULT proves this by two Examples, very pat to the purpose, viz. by the Division of Gold which is made by the Gold-beaters, and the partition of the same Gold made by the Wire-drawers.

For the Gold-beaters of one ounce of Gold, make 2790 Square Leaves of Gold, each side of which contains two inches and ten Lines; and if we deduct hence the Waste Pieces that are cut off,

X. What Quantities are Incommensurable. Fig. 1.

XI. The Divisibility of Matter Demonstrated.

XII. An Objection on against the Divisibility of a Body.

XIII. The First Answer.

XIV. The Second Answer.

XV. The Incomprehensibility of the Divisibility of Matter is no Argument against the Truth of it.

XVI. The Divisibility of Gold by Gold-beaters.

which almost reach to one half of it, the surface of every Leaf of Gold will be found to contain 1156 square Lines; so that all of them joyned together side by side, will make out a superficies of 3155880 square Lines. And if we add to this the Third part thereof for the Loss in the making, it will follow that the Gold-beaters out of one Ounce of Gold, beat 4270840 square Lines. Seeing therefore this Number includes 159092, the quantity of the Basis of the Cube of one Ounce weight, it is without doubt that that Cube, which contains only five Lines with a Seventh part in height, is at least divided into 159812 square Segments.

XVII.
The Division of Gold by Wire-drawers.

And tho' this Division of Gold into Leaves be very surprizing, yet is it much Inferiour to that which is performed by the Wire-drawers. These have commonly lying by them many pieces of Gold of a Cylindrical figure, being every one of them of 16 Marks weight; one of the most regular of which pieces was shewed to the foresaid Philosopher, the length whereof was of two Inches and nine Lines, so that the Cylindrical superficies of it was of about 12672 square Lines: This Superficies being cover'd with many Leaves of Gold, which put together weighed an Ounce and an half, was through the holes of a perforated Plate, drawn into Wire of the thinness of an Hair. Of this Thred he took 150 Foot, which he found upon exact weighing to weigh 36 grains, wanting a part of a Grain: So that the foresaid Cylindrical Mass, at this rate, must make a Thred of 307200 Foot long; whence follows, that it was drawn out 115200 longer than it was at first, and consequently that its superficies did exceed its first length above 340 times. If we add to this, That this thin Thred may be beaten into a Leaf, and thereby obtain a superficies twice as big as it was before, and so will exceed its first Magnitude 680 times, and consequently make 80616960 square Lines: And that after the whole Thred is thus beaten into a Leaf, the superficies of it is all cover'd with Gold: It follows thence, that one half Ounce of that Metal, whose Leaf is cover'd with Gold, is to that degree attenuated, that the superficies of it consists of 80616960 square Lines. Wherefore seeing that quantity contains 325795 times 26 Lines, and $\frac{2}{3}$, which is the value of the Basis of the Cube of Gold of one Ounce, it necessarily also follows, that the Thickness of Gold, which covers the gilt Leaf, is at last reduced to the $\frac{325795 \frac{2}{3}}{2}$ part of the half of the height of one Ounce; so that the quantity of five Lines, with a seventh part, hath at this rate been divided into 651590 equal parts.

XVIII.
Every thing that we cannot comprehend, is not therefore impossible.

And lastly, If we consider that this Division of Gold might still be carried further, if the Metal so extended were not design'd to certain uses, which cannot permit any further attenuation of it; as likewise that there are many Agents in Nature, who carry their work to a greater degree of Subtlety and Tenuity, it will still appear more clearly, that that is not impossible which our Imagination cannot perceive or comprehend.

XIX.
Matter is impenetrable.

Another property of Matter is, Impenetrability, which, tho' Negative, agrees to a Body, as well as Divisibility. For since to be Extended, is nothing else but to have Parts distinct from each other, it implies a Contradiction, that one Part should take

up the place of another, or that one Part should be contained in the other, or (which is the same) that one Part should be another. For it cannot be conceived, for Example, that the Part A of an Extended thing, should penetrate the Part B equal to it, without conceiving the middle Part of the Extension of A to be taken away or annihilated; now that which is annihilated cannot penetrate another thing. Besides, since any determinate Body, Ex.gr. of a Foot long, hath all things necessary to the constitution of such a Quantity, there can no other Body of a Foot long be added to it, without making an Extension of two Foot: And to reduce them by Penetration to one Foot, is not so much to joyn one Body to another, as to destroy it; and therefore we must conclude, that Matter is impenetrable, and that Penetration and Extension can never agree together.

Whence it is evidently deducible, that Mensurability, Divisibility, and Impenetrability, are the Properties of Matter, because they always accompany it, and can never be separated from it. For that I call the Essential Property of any Subject, which we conceive to agree with any Subject, and which necessarily follows it: As, it is the Essential Property of a Triangle, that two of its sides taken together are greater than the third; Or, that three Angles are equal to two right ones, because these so agree to a Triangle, as necessarily to accompany and inhere in the same.

XX.
Mensurability, Divisibility, and Impenetrability are the Properties of Matter.

CHAP. V.

Of the Division of Matter into Sensible and Insensible Parts.

THo' Motion be only the Mode of a Body, and cannot be conceiv'd to be without it; yet is it so much conducing to the Beauty and Harmony of the World, that all the Matter in it would be without Form, if it were not divided by Motion, and cloath'd with those Affections we find in the several parts of it. Hence it is the Philosophers tell us, That Nature is the Principle of Motion and Quiet, because by means thereof Material Substances acquire that variety we observe in them. By Motion Bodies get Heat, and by Rest they become Cold. But when Philosophers define Nature to be the Principle of Motion and Rest, they are not so to be understood by us, as if all the variety we find in Matter were the effect of Motion and Rest, forasmuch as that depends also on the Magnitude, Figure and Situation; but only that they are the Principal Attributes of Natural Bodies. For there is no question, but that from the Beginning, Motion made the distinction of Bodies, and gave them those Qualities and Affections, which we find in them. And hence it is, that Sensible and Insensible Parts do arise.

Sensible Parts are those, which being made up of many Insensible ones, do affect the Senses. Insensible are those, which because of their smallness do not fall under Sense, and are only known by their Effects, or the Discourse of Reason. Neither can we doubt of the Existence of such Parts in the World, if we thröly examin the Nature of a Body, and consider the Inseparable Properties that belong to it. For every Body is Divisible, so as that we can never come to the last Particle of it; though it be certain, that by continual Division, we

II.
Some are Sensible, others Insensible.
III.
There are Insensible Parts in the World.

we shall at last come to a part, which because of its littleness, will not be perceived by our *Senses*, and yet will not therefore lose the *Nature* of a *Body*; because as *Division* doth not constitute the *Nature* of a *Body*, so neither can it destroy it. Wherefore, there are *Insensible parts* in *Matter*, which none of the *Organs* of our *Senses* can give us any notice of.

IV.
Fluid Bodies consist of many Insensible Parts.

This appears most of all in *Fluid Bodies*, which consist of such small parts that no *sense* can perceive them. Thus we see that *Flesh*, *Bread* and other things are spoil'd by the *Air* and *Water*; but how this is done our Reason only can inform us: for we gather from the effects that some *Insensible Particles* of the *Air* and *Water*, insinuating themselves into the *Pores* of the *Flesh* and *Bread*, do there settle themselves in a manner contrary to their constitution as to *Figure*, *Motion*, *Situation* and *Rest*; wherein the *Nature* of *Corruption* doth precisely consist. For we cannot conceive any *Body* to be corrupted, but by the accession of some foreign parts, which are contrary to those of its first constitution: And forasmuch as these small particles are not discoverable by any of the *Senses*, they may well be call'd *Insensible Parts*.

V.
All Bodies cannot affect our Senses.

Neither is it any matter of *Wonder*, that these *Least particles* do not affect our *Senses*; because our *Nerves*, by which we perceive external things, are like to so many small *Cords*, that are Compounded of many *particles*, less than themselves, and therefore cannot be shaken by the least of *Bodies*; and consequently cannot carry external *Bodies* to the *Brain*, where the chief *Seat* of the *Senses* is. And I suppose every *Rational Man* will own, that it is much better to judge of what happens in little *Bodies*, not subject to *Sense*, suitable to what our *Senses* perceive to happen in great *Bodies*, than to invent I know not what strange things, which have no likeness at all with the things we do perceive by our *Senses*.

VI.
From our Clothes, Iron, &c. Particles proceed, which no Sense can give us any notice of.

Besides, we do daily experience, that a *Knife* loseth certain of its small *Particles* by being *Whetted*, and that many such like wear away from our *Clothes*, neither of which are perceived by our *Senses*. For the *Polishing* of hard *Bodies*, and the wearing away of *Woollen-cloth* or *Silks*, is done by the loss of such *Parts*, as our *Senses*, by Reason of their smallness, cannot discern. Wherefore it is most certain, that there are parts of *Matter* which cannot be discern'd by themselves, tho' being joyn'd with others they can make up a sensible *Body*: This being a thing easily demonstrable by the growth of *Bodies*; and is acknowledged by Divine *PLATO* in his *Timæus* in these Words: Concerning these little *Bodies*, we are to conceive thus, that if they be taken singly by themselves, none of them, because of their *Parvity*, can be seen by us, whereas when many of them are joyned, their *Bulk* presently appears.

VII.
We are to Philosophize of Insensible parts after one and the same manner.

Wherefore we are to *Philosophize* alike of *Insensible* as of *Sensible Parts*. For as we own some *Bodies* to be compounded of *Parts*, actually distinct from each other, (as we see small *Dust* in *Stones*, and *filaments* in *Flesh*;) so likewise it is consonant to *Reason*, to admit other parts of the same kind, which because of their *Smallness* cannot be perceived; and their *Analogy* persuades us to Judge and Discourse of them both after the same manner: Seeing that without them, the *Qualities* and *Opera-*

tions of *Bodies* cannot be explained. For how can I apprehend the cause why *Oil* is more easily congeal'd than *Water*, without conceiving the *Particles* of *Oil* to be hooked and *Branchy*, which makes them more easily to cleave together, than those of *Water*? And that *Water* is more hard to congeal, because its *Parts* are slippery, and united together, as *Eels* are, as shall be said hereafter. And yet no *Body* ever discern'd either the *Parts* of *Oil* to be *Branchy*, or those of *Water* to be figured like *Eels*. And therefore it is evident that in *Natural things*, there must be *Parts* allowed, that are only discernible by the *Understanding* or *Imagination*.

Neither are we from hence to infer, that such *Particles* as these, are *Atoms*, that is, altogether *Indivisible*: For being *Parts* of *Matter*, they must need include *Extension*; and it implies a *Contradiction*, that what is *Extended* should be *Indivisible*; for every *Extended Being*, hath *Parts* distinct from each other, and consists of *Divers Dimensions*, which cannot be said of *Atoms* or *Indivisibles*: Neither can we conceive any *Insensible Parts* to be so solid, as not to be *Naturally Divisible*: Nor is any *Body* so compact, but that by a strong *Motion* it may be dissolved; or if we should suppose this impossible to the *Powers* of *Nature*, yet we cannot deny *God* the Power to do it; seeing there is nothing else required to the *Divisibility* of a *Body*, but its *Extension*, and that it be Subject to those *Affections* which constitute a *Body*, as hath been said before.

Moreover these *Atoms* are of several *Figures*; now whatsoever is *Figured*, must have *Parts*, which *Parts* as they cleave together, whilst they are at *Rest*, so are they disjoyn'd again, whenever there is made an impulse upon them, strong enough to overcome their *Rest*. And this cannot but happen in that hurry, wherein the *Particles* of *Bodies* are continually tost to and fro.

Wherefore we conclude that there are no *Atoms*, or *Indivisible Parts* of *Matter*, but only *Bodies* of an *Indefinite Littleness*, which are continuous, and by the interposition whereof other *Bodies* touch one another. For the *Sensible Particles* do not properly touch one another, but are rather like *Baskets* made of *Twigs*, which cannot be immediately united together, but borrow all their continuity from the *Insensible Parts*, by the various *Inflexion* and *Disposition* whereof they become *Contiguous*, as shall be hereafter shewn at large.

CHAP. VI.

Of the Three-fold kind of Matter, and that there are no more than Three Elements of the World.

THE exactest Method of handling *Sciences*, as to my Judgment, is to deduce the thing under Examination from its first Original, and diligently to search from what *Principles* it doth proceed. This is the common way of *Philosophers*, who do not begin their *Treatises* with *Compounds*, but *Premising* things that are simple, proceed from them, to those that are compounded, and the manner how they are made up of them. This is the way used by *METAPHYSICIANS*, who beginning with

VIII.
Insensible Parts are not therefore to be accounted Atoms or Indivisible

IX.
They are Figured.

X.
And are Indefinitely Divisible.

VI

In Sciences we are to proceed from Simple things to compound.

with *Entity* in common, from thence come down to a *Body*, which is its *Species*, and afterwards divide it, into a *Terrestrial* and *Celestial Body*. And the same is observed by *GEOMETRICIANS*, who do not presently consider a *Body* as it consists of three *Dimensions*, but first of all imagin an *Indivisible Point*, which by its course or the diffusing of it self makes a *Line*, which is a *Length* without *Breadth*. Afterwards they suppose this *Line* to move crosswise, whence ariseth an *Extension* bounded by *Lines*; and to this they give the name of *Surface*, which is *Length*, and *Breadth*, without *Profundity*. And lastly from these multiplied ariseth a *Body*, extended in *Length*, *Breadth* and *Profundity*.

II.
God did not proceed thus in the Creation of the World.

Which way of Teaching tho' it be very suitable for the Demonstration of *Natural* and *Metaphysical Objects*; yet did not God make use of it in the Creation of the World. For he did not first produce an *Entity* in General, then a *Body*, and last of all *Heaven*, *Earth*, *Plants*, &c. Neither did he first constitute a *Point*, from the *Motion* whereof a *Line* might arise, from *Lines* a *Surface*, and from multiplied *Surfaces*, a *Body*. But tho' I own that the *World* in the first moment of its creation was perfect, and that it was not increased by vicissitude of times, yet it will not be absurd for me to establish some *Principles*, whence we may suppose that *Natural Things* have been produc'd, tho' they were not in that precise manner created by God. Because those things are more clearly known by us, which are deduced from a *Principle*, and by a continual vicissitude are brought forth and encrease, than such as are consider'd in an absolute state of Perfection.

III.
Physicians do the same in their treating of Plants and Animals.

Thus *Physicians* in order to their explaining of the Generation and growth of a *Chicken*, begin with the *Egg*, and shew what parts are daily fram'd therein, by the Incubation or brooding of the *Hen*. And so they who examine the nature of *Plants*, begin with their first Original and Propagation, and then proceed to the considering of them in their Sprouting, Growing, Blooming and bringing forth *Fruit*. For as *ARISTOTLE* saith in his *First Book of a Commonwealth*, he that takes a view of things in their First Rise, will best of all perceive the Truth of them.

IV.
The first thing suppos'd is, that at the Beginning the Parts of Matter were divided by Motion.

Let us suppose therefore the Matter of the Universe to be put into *Motion*, and that it was divided by God into *Parts*, much of an Equal *Bigness*, not round, because many round *Bodies* put together, touch one another only in a point, and consequently leave many Empty Spaces) but into *Parts* of another *Figure*, and of a mean bigness between those that constitute the *Heaven* and the *Stars*, which we suppose to be whir'd round about their own *Centers*.

V.
The Original of the First and Second Element.

This being suppos'd, it will be easily made out, how the *Elements* came to be; for of whatsoever *Figure* we imagine the *Parts* of the *World* to have been, so they have but several *Angles* and *Sides*, it must follow that by running against one another, their *Angles* must by degrees have been worn away, and their *Figure* thereby chang'd to Roundness. For by an *Angle* we understand nothing else, but that Prominency which hinders a *Body* from being round; which *Angles* being worn off, a *Spherical Body* must thence arise. For *Bodies*, whir'd by various motions for a long time together,

do at last become round, as appears in those things that are turned. And the parts of this Matter are called the *Second Element*.

And forasmuch as a *Vacuum* implies a Contradiction, and that all spaces are fill'd with *Bodies*, there must be some more subtil Matter to fill the intervals that are found between those small round *Bodies*, which is performed by those *Particles*, which like *Shavings*, are rub'd off by Motion from *Bodies*; for they being very slender and flexible, easily accommodate themselves to the *Figures* of the *Bodies* they are contiguous to. Moreover by this *Attrition* or Rubbing against one another, they have obtained a very great degree of *Swiftness*; so as that by the meer force of their *Motion*, they are further divided into innumerable *Particles*, and are sufficient to fill up all the little spaces left between the *Globuli*.

Now tho' this Matter be very subtil, yet we must not think that all the parts thereof, are of the same smallness, as appears in *Sawdust*, or in *Filings*. Wherefore the lesser of those particles will be more easily moveable than the thicker and bigger; and the *Particles* of the *First Element* will move more swiftly than those of the *Second Element*: For tho' they receive their *Motion* from these latter, yet because of the ways they must run through, their *Motion* must needs be accelerated: For whilst the *Globuli* of the *Second Element* pass through streight or right-on, and open ways, they thrust those through narrow and cross ways. And indeed we find by Experience that the narrowness of Passage conduceth much to swift Motion, as we find in a *Bellows*, whence the *Air* proceeds with great swiftness, by reason of the narrowness of its *Nuzzle*.

But tho' most parts of the Matter be *Round*, and that the *Particles* that are worn off from them, be such as I have now described, yet we must suppose that many parts of the Matter, having been bigger, and of more irregular *Figures* than the rest, it was more easy for them to join themselves with many others, than to become round; and these are they that constitute the *Third Element*, which we may call the *Element* of the *Earth*, because the parts of it have little or no Motion, whereby they might change their situation with regard to one another; in like manner as we may call the *First*, the *Element* of *Fire*, because of its subtilty, and the swift agitation of its Parts; and the *Second Element*, that of *Air*, because its Parts are bigger, and less agitated than those of the *First Element*.

But from this supposition, that the Matter of the *First Element*, did at first arise from the hitting together of the *Globuli*, one difficulty does arise, viz. that it seems to follow from hence, that this Matter ought to encrease continually, because the *Globuli* of the *Second* hitting one against another incessantly, must needs strike off some *Particles* from each other, and that consequently the *Sun* and fixt *Stars*, which consist of this *Element*, must be encreased continually by reason of a never ceasing affluence of new Matter.

This Difficulty may be easily answer'd, by considering the mutual *Conversion* of the *Elements* into each other. For from the Matter of the *First Element* sometimes a thick *Body* is made, as may be seen in the *Spots* that grow about the *Sun*, and obscure

VI.
The Matter of the First Element, fills the Spaces that are left between the foresaid small Round Bodies.

VII.
The Parts of the First Element are not of the same Bigness.

VIII.
The Rise of the Third Element.

IX.
How it comes to pass that the Matter of the First Element, doth not encrease continually.

Answer.

obscure some part of its light. For if we examine their first Original, we shall find that at the Beginning, they are very thin Bodies, which repel the impulse of the Particles of the First Element, which by running against them, cleave to them, and being condensed by the Motion of the Sun's Substance, become big and Opake Bodies. And by this means the First Element, is turned into the Third, which being afterwards dissolved, becomes again the First Element by acquitting its former swift agitation, and by being divided into Particles of Indefinite Parvity.

XI. Wherefore being resolv'd to deviate from the Sentiments of the Antients, since we want other Latin Words whereby to express them, we will distinguish the Names of these Elements only by Numerals, and call them the First, Second and Third Element.

XII. By the First Element, we understand with Des Cartes, a most subtil Matter very swiftly agitated, fluid, and keeping to no certain figure, but which suits it self to the Figure of those bodies that are about it. By the Second Element, we mean very small Globules, that is, Bodies exactly round and very solid, continually whirled about, and which do not only like the First Element, fill up the Pores of Bodies, but also constitute the Purest Substance of the Ether and Heaven. By the Third Element we understand a Matter consisting of thicker and Branchy Parts, full of Angles and unfit for Motion, of which the Earth, Water, Air, and all mixt Bodies do consist.

XIII. An Element therefore Generally taken, is a Formed Primordial Matter, whence the variety or difference of Bodies takes its rise. Or it is a simple Body, of which mixt Bodies are compounded, and into which they are resolv'd again at last. First, an Element is said to be a Matter Formed, because Elements were at first made out of Matter, by the Introduction of certain Modes into it. It is called Primordial, forasmuch as Elements are the Principles of mixt Bodies, not made of any other Bodies, as mixt Bodies are, but immediately produc'd from the Matter from which all variety of Bodies takes its rise, as proceeding only from the various Modification and conjunction of the Elements.

XIV. It remains next to shew that these three Elements of the World, are sufficient to explain all natural effects whatsoever, and that therefore there is no need of feigning any other. This will appear if we consider the several kinds of things in the World, for according to their Diversity we are to settle the Distinction of Elements. And seeing all Bodies may be reduc'd to three General Heads, just so many Elements, and no more are we to look for in the World. Now Bodies are either lucid or shining, as are the Sun and fixt Stars: and these are made of the First Element; or Transparent as are the Heavens, which transmit the Rays of the Sun and Stars; and these do consist of the second Element: Or lastly, Dark and Opake, which reflect the Rays they receive from Lucid Bodies, such as are the Comets and Planets, and these consist of gross and corner'd parts, which as we have said, do constitute the third Element.

XV. For it cannot be doubted but that the Sun and the fixt Stars are Lucid Bodies, as coming near the Nature of Flame, and exactly resembling all

the Properties of Fire; and therefore they cannot consist of any other Matter save that of the first Element: And the Heavens are said to be Transparent, and compacted of the Globuli of the Second Element, forasmuch as by means of them they transmit the Light to us. Now we must not imagine that these Globuli or Pellets of the second Element, are immediately joyn'd together, since that implies a Contradiction; but the subtil Matter runs between them, and takes up the places they themselves cannot fill because of their roundness. The same thing being also to be observed in other Bodies which reflect the Light, for a great quantity of the Matter of the first Element doth always pierce and permeate the Earth and the Planets.

Wherefore three sorts of Bodies are chiefly to be consider'd in the World; the Sun and the Stars which consist of one only kind of Matter; the Heaven which includes both the first and second Element; and the last or lowest, which contains all the three kinds of Matter, as the Planets and Comets.

You will say, it may be, that it is an Argument of Rashness and Profaneness to set down another order of conceiving of things, than God himself hath observed in the making of them; and that we cannot look upon things to be the effect of certain feigned Principles of our own which we know were created by the sole Command and will of God.

I answer, that it is no Argument at all of either Rashness or Profaneness, for a Man to distribute those things into many parts, which he cannot conceive all together, and to follow such an order of conceiving of things, as is consentaneous to the Laws of Nature establish'd by God, tho' he knows that God did not make use of this Order in the Creation of things. For otherwise not only all Philosophers, but Divines also would be found blameworthy. For do not Divines divide Gods Decrees into many, which notwithstanding in God are only one most simple act? They link divers Decrees in a certain order together, and suppose some of them to have been before, and others after, tho' indeed there never was any such Series or Connexion of Decrees in God. But who has ever undertakn to blame them for this? Except it be some of those, who that they may seem to be wise, will not stick to find fault with Heaven it self. Now if this may be done without blame in the Decrees of God, which are God himself; much more will it be lawful for us to conceive the Universe of Bodily things (which is different and diverse from God, and made by him in the space of six days) as successively springing from certain Elements by the wise and Powerful disposing of God. And the rather, because if God had will'd to produce this World successively from Elements, doubtless he might have done it, without any prejudice to his Power or Wisdom.

The Chymists, accounted by some the only Philosophers, and Natures Secretaries, hold five Principles, Mercury, Sulphur, Salt, Caput Mortuum or Dead Earth, and Phlegm; there being scarcely any Body out of which they cannot produce these several Natures, as they tell us. For that by the means of Fire, or some other Analogous Agent, they can so resolve things, that by separating the parts, whereof they were compounded, they can discern their several Forms and Quan-

ted Lucid, and the Heaven Pellucid or Transpa- rent.

XVI. Things compounded of the Elements.

XVII. Objection.

XVIII. Solution.

XIX. The Elements of the Chymists.

lities. Wherefore the more subtil part which they draw off by Fire, they call *Mercury, Spirit* or *Aqua vitæ*; the Thicker and Fatter part they call *Oil* and *Sulphur*; and the most fixed, which is left of all extracted, they name *Salt*. Besides these there remains behind a certain *terrestrial matter*, being the dregs or dross of the Resolved Body, which they term the *Caput Mortuum*, or *Damned Earth*; and a watry and insipid liquor they call *Phlegme*.

XX.
The Principles of the Chymists cannot be said to be first Elements.

These Principles of the Chymists, cannot be said to be the First Elements of things, as not being those things into which Bodies are resolv'd last of all, but such as proceed from them by a prior Resolution, after which they may be yet further resolv'd into much more simple parts, as the most experienced Chymists do confess. It hath been prov'd by a late Experiment, that a thick Oil distill'd from various Plants, hath been so rectified by many reiterated distillations, that at every Rectification an equal Portion of Common Water hath been added to it: And after many Distillations, they have got from it a quantity of Water, impregnated with much volatile Salt, besides a considerable portion of Earth, so that at last only a little thin Oil remained, of a great many ounces; which by more Rectifications might have been wholly resolved into Phlegme, Volatile Salt and Earth. So that neither the Burning Spirit of Wine, nor Oil it self, nor Sulphur, can be reckon'd amongst the first Principles of things, as being only secondary Concretions, which depend on such as are more simple.

XXI.
The Extracted Salts, are not simple.

Neither can I persuade my self that the Salts extracted out of the Ashes of Plants, &c. are so simple as not to consist of some thing more simple than themselves. For when I consider that Sea-fish, which for a great part, are nourished with Salt-water, have not the least taste of Salt; and on the contrary that Men and Beasts, who do not so much feed on Salt Things, do void Salt Urine, Sweat, and sometimes Spit too, I am very apt to persuade my self that Salt it self is not the first concretion of Parts, but only a secondary, and which depends only on a Mechanical texture.

XXII.
The Chymists do not, in this their Enumeration, comprehend all Principles.

These Principles therefore, notwithstanding they are so highly valued by the Chymists, do not comprehend all things out of which Bodies are compounded: For tho' they extract Waters by their Distillations, that is, the most slippery and flexible parts of Bodies, which they ascribe to Mercury: Oils also, that is, those Branch-like Parts that do easily entangle and hang together, which they attribute to Sulphur; and the remaining very thin parts, that are easily mixt with Water, and incorporate with it, which they refer to Salt: Yet all this while they make not the least mention of that subtil Matter, whose Existence we have here owned and asserted, and which is of absolute necessity to the composition of most natural things.

XXIII.
The Parts of Bodies are greatly changed by Distillation.

Moreover, who would own those things to be the Principles of Natural Bodies, which are quite changed, and have got another nature? For Fire being extremely active, cannot extract the parts of any compound, without violently agitating, and dividing them into less Parts, which Division cannot happen without a change of their Figure, and by consequence of their Nature. Now

Experience proves that the nature of things is alter'd by Distillation; because that after all the Parts into which a mixt Body can be resolv'd, are put together again, that which thence ariseth is not the same with that it was before, but is quite of another Nature.

We may add this also, that the Chymists deceive themselves by making only five Elements; because according to the Method and way whereby they have found out these, they may procure a vast greater number of Elements, yea such as the Mind of Man cannot reach. For the same Mercury is not drawn from all Bodies; nor the same Sulphur, seeing that which is drawn from Wine is very different from that they get out of Oil. Neither is it the same Salt they extract from all Plants, since that of the Ash hath a Caustick Virtue, which the Salt of Oak hath not. Wherefore we must conclude that Mercury, Sulphur and Salt are no Elements, because Elements are simple, and common to all mixt Bodies.

Moreover it is very probable that these five Principles do only differ by the Texture of their parts; neither do I think that Oil differs from Spirit, save only in this, that the Parts of Oil, are by a long Fermentation, divided into smaller parts, and furnish'd with lesser branches, whereby they are less apt to adhere to Bodies, and with more ease flee away from them. That it is so indeed, we may conclude from this noted Experiment, that from Plants and Juices much Oil is got before Fermentation, but very little Spirit; whereas if you distill them after Fermentation, you shall have much Spirit, but a very small quantity of Oil.

XXIV.
According to the opinion of the Chymists there are more than five Elements.

XXV.
The Chymical Principles presuppose a certain Texture of Parts.

CHAP. VII.

There are no Substantial Forms really distinct from Bodies.

They that follow ARISTOTLE, or rather his Interpreters, do all agree in this, that there are Substantial Forms, which together with the Matter constitute one Compound. By the name Substantial Form, they understand a certain Substance united to matter, which together with it constitutes a meer Bodily compound. Tho' both these parts are Bodily and Divisible, yet they assign a difference between them; as that the Form is more a Substance than the Matter, because they consider it as Subsisting by it self, and is therefore by them called *Actus* or Actuality; whereas they will have the Matter to be only *Potentiality*, which is perfected by the Form, from which also it derives all its Existency. Upon which account Matter is frequently call'd by ARISTOTLE a Non-Entity, a Non-Quiddity, and Non-Quality.

Tho' this Opinion be commonly approv'd of in Schools, and that they are accounted no less than Hereticks that reject it, yet Reason obligeth us to depart from it, and publickly to profess that Substantial Forms are of no use in Natural Philosophy for the explaining of the Principles or causes of natural things; yea, that all Natural Effects can better be explained without them. And the chief reason that persuades us to explode these Substantial Forms, is from their own nature. For there can be no substance that begins to be in the Nature of Things, which is not created by God; forasmuch as every thing, both as to its Essence and Existence depends on him; so that if there be any thing

I.
What the Peripateticks understand by Substantial Forms.

II.
There is nothing new in Nature which is not made by God.

thing that begins to be, we may truly say of it, that it is produc'd by God: But many *Substantial Forms* according to them do daily exist anew, and yet are not suppos'd to be created of God by those that admit them; therefore there is no ground at all for them.

III. To confirm this; what becomes of *Substantial Forms*, when they are separated from *Matter*? Do they still continue, or do they perish? If they continue, whither do they betake themselves? What is their *Virtue*, or how do they work, being separate from *Matter*? If they perish, as all do own, by what force are they destroy'd or annihilated? Since *Annihilation*, as well as *Creation*, belongs to God alone; and that it is only the *Work* of an *Infinite Agent*, to reduce an *Existing Thing* to *Nothing*? For every single thing, always continues in the same state, except it be alter'd by an *External Principle*; now it is repugnant to the Goodness of the *Creator* to produce things, that have in themselves the *Principle* of their own *Destruction*.

IV. And after all, none of the Asserters of *Substantial Forms*, can produce one single Instance that ever any *Substance* was wholly destroy'd; but will of its being chang'd into something else, and taking a new *Figure*. 'Tis for this cause only that the *Rational Soul* is said to be immediately created by God, because it is a *Substance*. For a *Material Accident*, according to their Opinion, is not *Created*, but produc'd from the Potentiality of the *Matter*, after the manner of *Substantial Forms*; wherefore, since these *Substantial Forms* are not suppos'd to be created, neither ought we to think them to deserve the name of *Substance*.

V. This may also be proved another way. For *Substantial Forms* were only invented by the *Peripateticks*, to make out the *Causes* of all *Actions*, that are found in *Natural Things*, whereof they are the *Principles*, from whence they do proceed: But these *Forms* are of no use to the explaining of all these effects; seeing that they themselves own them to be *hidden*, and that their *virtues* are not known to them. For whatsoever is clearly perceiv'd in *Bodies*, the same according to them is deny'd to be the *Form*, which they say lies hid in *Bodies*, and which they own to be imperceptible by the *Mind* it self. Wherefore when they say that some *Action* proceeds from *Substantial Forms*, they may well be reproach'd for having recourse to a *Principle* of *Actions*, the nature whereof they do not conceive, and by consequence neither can any thing of certainty be gather'd from it: Which alone, in my Judgment, is sufficient to reject them altogether, forasmuch as nothing is to be admitted in *Philosophy*, which is not clearly and distinctly perceived and known. For what can be more unworthy of a *Philosopher*, than to make those the *Principles* of *Bodily Things*, which he can neither explain by *Definition*, nor demonstrate by *Experience*, nor conceive in his *Mind*?

VI. Would you take him for a *Philosopher*, who being asked about the *Nature* of *Fire* and *Water*, should tell you that *Fire* is *Fire*, and *Water*, *Water*? For is it not much the same thing, to say that *Fire* and *Water* are such by their *Substantial Forms*? Or would you think him to be an *Interpreter* of *Nature*, who being demanded about the *Phases*, or *Appearances* of the *Moon* or *Venus*, and the

Principles of the *Stars*, would answer, that they proceed from *Forms*, as from their *Inward Principles*? What is this but to call all things by one name, and comprehend them under one and the same *Notion*?

But you'll say, it is dangerous to reject all *Substantial Forms*, forasmuch as this may be an occasion of doubting, whether there be any *Substantial Form* in *Man*, because we see the same operations in *Brutes*, which are perform'd in us. I answer, that the contrary ought rather to be inferr'd from hence; for by admitting *Bodily Substantial Forms*, and such as are subject to *Death*, it may be doubted, whether such *Forms* be not also in us, as they hold to be in *Living Creatures*; whereas by utterly rejecting them, we extol the Dignity of *Souls*, by declaring them alone to be *Substantial Forms*, and that all the rest consist only in the *Motion* of the *Animal Spirits*, *Configuration* of *Parts*, &c. as shall hereafter be declared more at large.

But the *Soul* of *Man* being a *Substantial Form*, cannot be an *Argument* to prove other *Substantial Forms*; because the *Soul* of *Man* is a *Spirit*, wholly distinct from *Matter*; whereas other *Forms* are all of them *Material*, and consequently extended: whence we must conclude that they are *Modes* of *Matter*; or if any of them be *Substances*, they must be *Bodies* of a particular *Nature*, which united to other *Bodies*, constitute *Natural Compounds*.

Wherefore the *Schoolmen* certainly differ from *ARISTOTLE*, when they assert the *Forms* of *Natural Beings* to be *Substantial*. He indeed owns the *Form* to be *idea*, but by this word he doth not mean *Substance*, which belongs to the *General Nature* of *Body*; but *Essence*, which relates to the *Special Nature* of a *Determinate Body*. As for example, the *Form* or shape of *Apollo*, is of the *Essence* of the *Statue* whereby *Apollo* is represented, but yet is not of the *Substance* of it, as the *Stone* or *Wood* is of which it is made.

But they will urge further, and say, that *Brute Animals* differ amongst themselves, but they cannot differ by the *Matter*, because that is the same in all viz. a thing extended in *Length*, *Breadth*, and *Depth*. Therefore there must be a *Form* by which they may be distinguished from one another. The Major is proved from *Scripture*, which saith that God created the *Living Creatures* according to their kinds, and the *Fowl* of the *Heaven* according to their kind.

I answer, that we freely grant all this. For the names of *Genus* or *Species* do not always denote *Substantial Differences*, but sometimes only *Accidental ones*: And this way *Animals* do differ, who are differently disposed and moved; much in the same manner as *Clocks* may be said to be distinguished, because they have various *Motions* according to the different ways after which they are made. For not only *Substances* differ by *Species* or by *Genus*, but also *Modes* and *Accidents*; for a *Round Figure* doth no less differ specifically from a *Square*, than *Beasts* and *Fowl* do; and yet no body will be so senseless to assert, that those *Figures* differ by *Substantial Forms*; since neither of them include any thing of *Substance*. And so likewise *Beasts* and *Fowl* are said to differ, because *Matter* is variously dispos'd and modified in them.

You

XII.
Another
Objection
drawn
from the
Difference
of Bodies.

You will say that there are many Bodies in the Universe which do essentially differ, as Honey, and Wormwood; and that this Essential Difference cannot proceed from any thing, but from Substantial Forms; seeing that the Accidents that are in Honey and Wormwood, as to their Figure or Disposition of Parts, may be changed, whilst the Honey and Wormwood still continue the same.

XIII.
Solution of
the Diffi-
culty.

I answer that Honey is constituted such as it is by its Form, and so essentially differs from Wormwood: But that this Form is a Substance I utterly deny, because the difference of these two, is only from the different configuration, situation, &c. of their Parts. For tho' it be accidental to Matter in general, to have the configuration of the Parts of Honey or Wormwood; yet is it essential to Honey and Wormwood, to have such Modifications, to make them such Bodies. But of this more hereafter.

CHAP. VIII.

That there are no Qualities, or real Accidents distinct from Substance.

I.
What the
Peripateticks
Understand by
Accidents.

THE safest way to arrive to the knowledge of those things we enquire after, is to separate them from one another, and by this means distinguish what is obscure, from what is clear in them. But in the Observation of this Rule, we must have a care not to encrease the number of Objects, or to assign Existence to such things, which indeed cannot exist. Which some seem to have done by distinguishing Qualities and Accidents from Substances, and taking them for Real Entities, having a distinct Nature from the Subjects in which they are found. For they have defined them to be Things adventitious to Subjects, and that are by Nature distinguished from them. And will have their Essence to consist not in an Actual, but Aptitudinal inherence, to shew that Accidents may exist separate from their Subjects.

II.
They Con-
found Sub-
stance with
Accidents.

But certainly they are in a great mistake, seeing that they confound the notion of an Accident with that of Substance, whatever they may say to the contrary. For every thing that is real involves an Aptitude to exist, and therefore is a Substance; seeing by a Substance nothing else can be understood, but a Thing, which stands in need of the Concourse of God only to exist; which how truly it agrees to an Accident, no body will deny, that owns an Accident to be something Real, and that it can exist separate from its Subject. Moreover, whatsoever is evidently and distinctly known by us, the same is true: But I clearly understand an Accident to be a real thing, and that it can exist independently of its Subject; Therefore an Accident is to be called a Substance; forasmuch as nothing else is contained in the Conception of a Substance. For no stronger Argument can be alledged to prove that two Things are the same, than that they have one and the same Definition.

III.
If Acci-
dents be
Real En-
tities they
may exist
by them-
selves.

But you will say, that Accidents are very weak Entities, which stand in need of a Subject to support them, and that therefore they do not deserve the name of Substance. If this Answer were sufficient, it might as well be said that the Animal Spirits, and all insensible Particles of Bodies, ought to be reckon'd amongst Accidents, because they

also want a Subject to support them, and from whence they have their permanency. It is sufficient to the nature of a Substance, that it be an Entity fit or apt to exist. Now forasmuch as Natural Accidents, which ARISTOTLE defines in his first Chapter of Prædicaments, are such Entities, and that Existence is no where to be found but in those Entities, we may well say that they subsist of themselves.

And whereas they say that Accidents cannot naturally exist separate from Matter, but only by the Divine Power; this is nothing to the Purpose; for Gods Power doth not destroy the Nature of things, nor impart any new thing to them. Wherefore, if every thing that can Naturally be separated from its Subject be a Substance; then that also which by the Almighty Power of God can be without a Subject, may as well deserve the name of a Substance. And as to what they say that Accidents separated from their Subjects, do by a natural propensity require to be restored to them again, neither will this do them any service at all: For as a Bodily Substantial Form, which supernaturally can exist separate from its Subject, whence it is brought forth, doth not therefore cease to be a Substance, because of its natural propensity to be united to Matter; so neither doth an Accident, that admits the Definition of a Substance, cease to have the Nature of a Substance, tho' by a Natural Propensity it requires to be placed in a Subject. Neither will this Exigence ever be able to hinder an Accident from being look'd upon as something Subsisting, which is sufficient to constitute the Nature of a Substance.

I cannot imagin why the Peripateticks take so much pains to introduce Accidents into the World, when if there were any such, they could not be perceiv'd by any of our Senses: For every Sensation is perform'd by Contact; now nothing but the Superficies of Bodies can be toucht; and that Surface which is toucht, is not a Real Accident, as they falsely imagine, but only the Mode of a Substance, as consider'd without Profundity. But they will say that Real Accidents are to be admitted in order to the explaining of Sensation: But neither is there any Necessity for this; since nothing is requir'd to the moving of our Senses, besides the variously disposed Superficies of Objects: For we may easily understand how from the different Magnitude, Figure and Motion of the Particles of one Substance, divers local Motions may be produc'd in another: But we cannot conceive, how by them any such thing should be made as a Real Accident is, that hath power to produce local Motions in other Bodies.

The thing will become more evident by an Example: What is it in a Watch that measures the hours? Is it any Faculty or Power distinct from the Watch it self? Certainly 'tis nothing besides the Magnitude of the Parts, the Fabrick of the Wheels, the Figure of the Spring, and other Mechanical affections that produce all those certain and constant Motions. Is there any virtue superadded to beaten Glass, which wounds the Membrans of the Guts, and makes it Poison? Not at all: For the same Glass being ground to a very fine Powder may be taken into the Body without any danger at all; and the Power in Beaten Glass of hurting the Bowels proceeds only from the Firmity or hardness of its Parts,

IV.
A Real
Accident is
a Substance,
if the De-
finition of
Substance
agrees with
it.

V.
Real Acci-
dents are
useless in
Natural
Philosophy.

VI.
This is
illustrated
by the Ex-
ample of a
Watch and
Beaten
Glass.

Parts, and the Figure of them, not from any Occult Quality, nor from a Faculty distinct from it, proceeding from the Glass itself.

VII.
Whatsoever
exists is
Substance,
not Acci-
dents.

Real Qualities, therefore, as they call them, are not to be admitted by a Natural Philosopher, as being repugnant to sound Philosophy, and cannot be understood, even of those, who will needs have them distinct from their Subjects as if they were Real Entities. For who could ever conceive a thing to be distinct from another, in which it is, and yet to have no Existence but what is dependent upon it? For every thing hath its own proper Existence, and whatsoever hath Existence, is without our thinking, in the nature of things, and therefore is no Accident. It seems a contradiction in Terms, to say that a thing exists, and yet wholly stands in need of the help of another that it may be; as will be evident to him that minds his own Thoughts and Conceptions, rather than the Words that are toft in the Schools.

VIII.
Substance
only is an
Entity.

Accordingly ARISTOTLE himself Book 7. Metaph. chap. 10. expressly asserts that Substance alone doth properly deserve the name of Being, or Entity; and that a Quality or Accident is not so much an Entity or Being, as the Entity of an Entity, or the Mode of a Being. For what is more contrary to Reason, than that that which hath no Essence of its own, but borrows its Existence from another, to which it is joined, should be reckon'd amongst Entities? For as one thing only is said to be found or Healthy, viz. an Animal; and all other things are said only comparatively to be so, so far as they have any reference to the nature of an Animal; so likewise we are to suppose, that Substance alone, according to propriety of Speech is an Entity, and all other things Analogically only, and with reference to that. Wherefore Quality in General is thus to be defined: A Mode of a Substance, or a certain adaptation of the Parts of a Body according to Motion, Situation, Figure, Magnitude and Rest. Forasmuch as from these a Body is denominated such like, and the Question What-like a thing is, may be fully answer'd.

IX.
Wherein
the Nature
of Acci-
dents or
Modes doth
consist.

I am not ignorant that the Asserters of Real Qualities, do support their Opinion by ARISTOTLE'S Authority; but I can never believe that so Great a Philosopher by Qualities did understand Real Accidents, but that thereby he only meant (as far as can be gather'd from the Examples he alledgeth) that there are divers dispositions of Parts in one Body, from what there are in another. In which sense I readily admit them, as supposing them only to consist in the Motion, Rest, Configuration and Situation of Parts. Thus Heat, for Example, is nothing distinct from the Fire, but is the very Substance of it, or the Flowing of its Particles, which penetrate and divide the Wood or any other Matter: So Figure is the Body it self, with regard to its being bounded by other Bodies from any further extension. So likewise Hunger, Thirst, Standing, and Sitting, are nothing else but various Affections or Mutations of a Body, which we consider as Modes, and not as Real Accidents, which may be separated from it.

X.
Agility,
Soundness of
Body and
Beauty are
not any

And the like we are to conclude concerning Agility, Health, Beauty, &c. For Agility is nothing else but a due Proportion of Spirits, and strength of the Nerves, that procure Bodily Motion. Health is nothing else, but a convenient

Temperament of the Humors, and Aptness of the Members of the Body, in that state which Nature requires. Beauty is a fit disposition of Members and Colours, in a due Proportion to each other. And whosoever pretends Qualities to be any thing else, I dare aver that he doth not understand what he asserts; seeing they cannot afford him any notice towards the apprehending of them, or any particular Idea concerning them. Nay he cannot so much as know wherein they consist, as shall be made evident hereafter in the case of Heaviness, Motion, and such like. Except he looks upon them as certain little Souls, under the notion of Spiritual Beings, which belong to Bodies, and perform the same in them, that our Souls perform in ours, when they move them.

A Modern Philosopher explains this point, by the Example of a Habit, which is defin'd to be an Adventitious Quality enabling the Subject to work with ease. Or, to use his Words; The Vigor, Ability and Readiness of a Natural Faculty, acquired by repeated Acts, enabling one to do that better, more readily and certainly, which he hath several times tried to do. For by frequent repeated Actions (or by an Extraordinary vigor communicated by Gods Special Grace) Habits are got, which are no new things superadded to our Soul, but only Modes, as when by frequent dancing, the Feet acquire a great degree of nimbleness, which Modifies the natural moving faculty.

We see in a Watch that when the Wheels are newly made, and rough, they move more slowly, which afterwards when the Surface of them has been worn and made smooth by long continued Motion, move more swiftly: Whence it is that frequently old Watches do Anticipate the time, and make shorter hours. But who will say that by this smoothing of the Wheels, any thing hath been added to them, besides a Modification? since all the change that hath happened to them is, that the Wheels are become more smooth and polished, and their Motion swifter than it was before. And the same must be said of our Mind, when a Habit is added to it, that it can now understand that more readily and easily, which before it naturally did more slowly and difficultly, which plainly is nothing else but a Modification, and not any new thing added to our Understanding.

Besides, if Accidents be Real, we shall never be able to know what Accidents belong to a Body, and what to a Spirit. For if Accidents have no Affinity with their Subjects, save this only, that they inhere in their Subjects, and yet are really distinct from them, we shall not be able to gather from the Perception of an Accident, whether the Substance in which it is, be Material or Spiritual; that is, from the Colour, Figure and Magnitude we shall not be able to conclude that it is a Body rather than a Spirit; neither shall we from Understanding and Willing, which are the Modes of a Spirit, be able to conclude, that the Substance endued with these Accidents is a Spirit: No more than from the Nature of a Body to which the Soul is joined, we can conclude that the Mind is a Body, or the Body a Mind.

Forasmuch therefore as we are ignorant wherein the Nature of a Quality doth consist, and can frame no Idea of it, it is unbecoming a Philosopher to make use of that for the explication of Natural

new things
superadded
to a Body.

XI.
Habits are
no new
things su-
peradded
to the Souls

XII.
The same
thing shew-
ed by the
Example of
a Watch.

XIII.
If we ad-
mit Acci-
dents to be
Real, we
shall not be
able to
know whe-
ther they
belong to
Matter or
Spirit.

XIV.
Wherefore
Qualities
are to be re-
jected.

Effects, which can neither be understood, nor defin'd, nor made out by Experience. But why then, may some say, are these Qualities admitted by the Peripateticks? Why, for no other reason but to mask and hide their own Ignorance, and that by fine words they may seem to know that, which indeed they do not. Accordingly if a Man ask them why such Medicaments purge, they will tell you, because of their Specifick Quality. Why doth the Loadstone draw Iron, or turns it self towards the Pole? Because such is its Occult Quality. How comes it to pass that the Bones of Mermaids stop Bleeding? Because they are endued with such a Quality. O excellent Philosophers! who know that the Loadstone turns it self to the Poles, that Fire is Hot, that a Coal is Black, Honey sweet, Gall Bitter, because of inbred Qualities, but altogether unknown and conceal'd from us.

XV. What are we to understand then by the word Accident, if they be not things distinct from the subject wherein they are? I answer, It is that which happens to an extended Substance; and therefore an Accident is not any thing Real, but a Mode depending on the Substance. Thus because we conceive the Roundness of a Piece of Wax, as having a dependent Existence on the Wax, we call it a Mode or an Accident. These Accidents have got several names, according to the several ways of our considering them; for as Substances are affected and alter'd by them, we call them Modes; as from them they are denominated such like, they are call'd Qualities; and when we only generally consider them as being in any Substance, we name them Attributes.

XVI. Whence it is evident that an Accident or Mode cannot exist without its Subject, nor pass from one Subject into another: for if that could be, it would follow, that when it was in the first Substance it did not absolutely depend on it, which implies a contradiction.

CHAP. IX.

What Intelligible Forms may be attributed to Natural things.

I. Matter being of it self sluggish and idle, and Substantial Forms, and Real Accidents having been rejected by us, we must take care to furnish it with some Forms, that may give to it variety and Distinction. For since Matter is a Passive Principle, we are to procure it some Principles, whereby it may be enabled to procure its effects: Which we shall easily meet with, if leaving the Schoolmen, we shall betake our selves to the Mathematicians, and build our Philosophy on their Principles.

II. For having defin'd a Body to be a Substance extended in Length, Breadth, and Depth, it remains, that in Initiation of them we consider in it Magnitude, that is, a determin'd Measure, which is call'd Continuous Quantity, or the number of its parts which is Discrete Quantity. Secondly, Figure, or the bounding Extremities of the Matter. Thirdly, its Situation, or disposal amongst other Bodies. Fourthly, its Motion, or change of Situation. Fifthly, its Rest, or abode in the same place. So that Quantity or Magnitude, Figure, Situation, Motion and Rest are the Intelligible Forms of all

Bodies, whence their Rise, Nature or Essence, and Properties do depend. A material Form therefore is nothing else, but a Complexion of Affections and Modes, that are accommodated to a thing, and to its performing several Actions. Which Form in a sound sense may also be call'd Substantial, as being the Form of a Substance, that is, of the Matter, which it informs and perfects. For Forms give to all Natural Bodies Substance, and Essential Difference, and are the Springs of the operations of every thing, and therefore may well be called Substantial: They are contained in these Verses.

Mind, Measure, Rest, and Motion,
With Figure, and Position,
To Matter join'd, the Causes be
Of all what here below we see.

The variety of these Modes is the Mother of Different things, and their Conjunction the Dispositive Principle of all Actions; which Art the Initiation of Nature abundantly teacheth us. For Artificial things do no otherwise differ from Natural, than that these for the curious contrivance, multiplicity and fitness of Organs do exceed the Former, and thereby witness the Transcendent excellence of the Artificer that made them.

Now that these Modes are the Forms of Material things, will appear more clearly, by assigning those conditions to them, which belong to Forms.

The First is, that the Form be proportionate to the Matter, so as to Determine and Define the same, which some call Actuating.

The Second, That as there is but one and the same Matter of all Bodies; so likewise there be but one common Form to them all, and such as shall affect them all alike.

The Third, That as all do own Matter to be a thing Extended and Divisible; so the Form also may be a thing known to all, and of the Existence whereof there can be no doubt.

The Fourth, That the nature of it be so clearly defined, that the notion may be as distinct, as is that of the Matter which it affects and distinguisheth. For it is the nature of Principles to be so clear and evident, that when the mind heedfully considers them, it cannot question their Truth.

Now that these I have mention'd are the true Forms of a Body, or that they impart a certain Mode of Being unto the Matter, will appear from hence, because all the foresaid conditions of Forms agree with them. As to the First, it is evident, that Matter derives its Distinction from Quantity, Motion, Figure, Situation and Rest: According as more or fewer of these are found in it. For the Diversity of Matter depends on Motion, without which there can be no separation of Parts. From Quantity it derives the Mode of its Extension. Figure furnisheth it with proportionate Extremities. To Situation it owes its position amongst other Bodies, whether upward or downward, forward or backward. Lastly, by Rest it continues in the same place, till by a stronger it be remov'd.

As to the second condition it appears also that these five Forms are common to all Bodies, because they affect and diversify not only Earthly, but also Heavenly Bodies. For Heavenly Bodies have their Magnitude, observe their distance and Situation,

III. From these the Distinction of things and their Actions do proceed.

IV. The Conditions of true Forms.

V. These Conditions agree to Quantity, Motion, and the rest.

VI. Magnitude Motion, &c. are common to all Bodies.

tion, some of them being moved about their *Axis*, others about their own *Center*, and are bounded by *Figures*, which by the juffling of other *Bodies* against them they change and vary.

VII. *Forms exist in Matter.* And according to the Third Condition, these *Forms* are apparent to, and own'd by all; to be in *Natural Things*, as being plainly discernible by us. For who is so dull and stupid as not to discern the *Magnitude*, *Figure* and *Motion* that is in *Bodies*, which are so obvious to his *Senses*? Neither in this do unlearned Men differ from those that are learned, since both own them alike; only the Unlearned considering chiefly their outside, judg them to be *Affections*; whereas the Learned searching more deeply into the Works of *Nature*, find them to consist in the insensible structure of the *Parts*, that by their smallness are not subject to our *Senses*.

VIII. *The Definitions of Forms are Evident.* As to the Fourth Condition, we cannot question but that the Definitions of these *Modes*, are easily deducible from this discourse, and are obvious and evident, not only to our *Senses* and *Reason*, but experience also.

IX. *Tho' these forms are not Substantial, yet are they Essential to some Bodies.* Tho' these *Principles* be only *Modes*, and like *Accidents* are attributed to a *Body* generally taken, yet may they be said to be *Essential* to the Works of *Nature*. For it is no contradiction to say that the same thing may be *Essential* and *Accidental* in diverse respects: Thus *Wisdom* is *Accidental* to a *Man*, but *Essential* to a *Wise Man*. *Sense* is the *Property* of an *Animal*, and yet is a *Genus*, with respect to the *Sight*, *Hearing*, *Smelling*, &c. In like manner, tho' *Quantity*, *Figure*, *Motion*, *Situation*, and *Rest* happen to *Matter* in Common, yet this doth not hinder but that they may be *Essential* to some Portion of it. Thus it is *Accidental* to *Iron* to be terminated by several *Figures*, as to be *Round*, *Square*, *Sharp*, or *Blunt*; whereas in a *Knife* the *Figure* constitutes its *Form*, and distinguisheth it from other things. For tho' *Iron* may be conceived without this or the other particular *Figure*, yet a *Knife* cannot be a *Knife* except it have such a determinate *Magnitude*, *Figure*, &c. So likewise *Roundness* is accidental to *Wood*, but is *Essential* to a *Wooden Bowl*. And in a *Clock*, *Magnitude*, *Figure*, *Situation*, the *Motion* of some parts, and the *Rest* of others, are accidental to the *Brass* or *Iron*, because without them they are still *Brass* or *Iron*; but a *Clock* can never have that name, without them.

X. *The Difference of Bodies depends on the Modification of their Parts.* So that the whole *Difference* of *Bodies* doth depend on the *Modification* of their *Parts*, which are distinguish'd according to the variety of their *Magnitude*, *Figure*, &c. as their *Identity* or sameness consists in the agreement of those *Modes*, and their observing the same *Proportion* amongst themselves. Wherefore, tho' a *live Man*, and the *Statue* of a *Man*, be alike in outward appearance, yet cannot they be said to be the same, because besides the *Soul*, which is in a *Living Man*, there is also great diversity of *Parts*, not only as to their number, but in respect of their *Magnitude*, *Figure*, *Connexion*, *Rest* and *Motion*.

XI. *Objection, that the operations of Matter do not depend on these Accidents.* But it will be objected, that these *Modes* cannot produce so many *Effects*, forasmuch as all *Actions* are attributed to the *Subjects* themselves, and not to the *Accidents*, which only operate by virtue of the *Substance*.

I answer, that we acknowled no other *Subject*, but *Matter* furnish'd with *Magnitude*, *Figure*, &c.

for *Matter* being passive, cannot operate, but by their efficacy. And tho' indeed *Matter* do not derive its *Essence* from these *Modes*, that is, tho' they do not make it to be a thing, yet do they cause it to be such a thing. Thus that a *Pen* is fit to write withal, and a *Key* proper to open a *Lock*, proceeds only from their *Disposition*, *Figure*, *Motion*, &c. for when these are taken away, they are no longer useful. Wherefore, *Accidents* do not operate, by *Virtue* of their *Substance*, as the Schools will have it; but the *Substance* rather works, by a *Virtue* borrow'd from its *Accidents*. Thus diverse *Weights* are lifted up by a *Beam*, according to the *Difference* of its *Situation*: Neither would *Iron* cut, if it were not provided with a fit *Figure* and *Magnitude*.

If you object that these *Principles* are not sufficient to explain all the *Phænomena* of *Nature*, because it cannot be made out by them, how *Warm Water* grows *Cold*, forasmuch as this change cannot proceed from the *Different Disposition* of the *Water*.

This change may very well be explain'd by our *Modes*, supposing *Heat* to be nothing else but a *strong and various Agitation* of *Particles*: For the *Water* by communicating its *Heat* to the *Air* and the *Neighbouring Bodies*, easily loseth it, except other succeed in the room of that which is lost; for by this means the *Water* is at length depriv'd of its strong agitation, and consequently returns to its former coldness.

Hence it is evident that the *Powers* of *Bodies*, or their *Faculties* of *Acting*, are nothing else but the *Magnitude*, *Figure*, *Contexture*, &c. of the *Parts* of *Bodies*: For by these all the effects we see in *Nature* are produced.

The *World* therefore is to be consider'd as a wonderful, and most Artificially contriv'd *Machine*, not the parts of it taken severally, but as joined and orderly complicated together. For as in a *Watch* we see many *Motions* performed only by the *Contexture* of its *Parts* and *Wheels*; in like manner all the *Agreement* or *Likeness* and *Difference* of *Bodies* proceed from their *Mechanical Affections*, viz. *Motion*, *Figure*, *Magnitude*, &c. As for example the *Power* the *Sun* hath, of attenuating *Water* into *Vapors*, of softning *Wax*, and *Hardning* of *Clay*, and of producing many other *Effects*, is not deriv'd from any new *Entities* added to it, or *Distinct Qualities*, but from its *Heat* only, which consists in the swift *Motion* of its *Insensible Parts*, which produceth several *Effects*, according to the different contexture of the *Body* it works upon.

It is evident from what hath been said, that there are only two *Principles* of *Natural Things*, viz. *Matter*, which is the same in all *Bodies*, and the *Form* whereby one *Body* differs from another; since it is certain that *Privation*, which the *Peripateticks* add to the two foregoing *Principles*, doth not deserve that name, as being a *Non-Entity*, from which consequently nothing can proceed.

Hitherto we have consider'd the *Nature* of a *Body* in *General*: We must next enquire into its *Affections*, which are nothing else but *Qualities*, *Attributes* and *Modes*, which agree to *Bodies*, according as they are said to be in this or the other state or condition; such as are those which we are

next to treat of, viz. *Rarity*, *Density*, *Heaviness*, and *Lightness*, &c. wherewith a Body is variously affected or indued.

CHAP. X.

What Rarefaction is, and how it is performed.

I. Rarefaction cannot be performed without the entrance of new Matter.

It appears from what goes before, that *Extension* is something that is not distinct from *Matter*, and that the one cannot be increased; but the other must be so likewise. Hence it follows, that in *Rarefaction* and *Condensation* the Constitutive Quantity of Bodies, is neither increased nor diminished; but only that in *Rarefaction*, the parts that were before United, are distended, so as some intervals are left between them, which are fill'd up by the entering in of some fluid and moveable Body; as is manifest in a *Sponge* swell'd with *Water*; and that on the contrary in *Condensation*, the separated parts are more closely united, by expulsion of those Bodies that fill'd up the Intervals; as appears in a *Sponge* out of which the *Water* is squeez'd.

II. What a loose and, what a close Body is.

A *Thin* or *Loose Body* is that whose parts are intercepted by *Spaces* fill'd with some *foreign Matter*, which afterwards may become a *Close Body* again by expulsion of the more *subtil Matter*, entered from without, by which means the parts come close together. Thus *Boiling Water* is rarefied in a *Pot* over the *Fire*; for we find that when it begins to *boil*, it swells up into *Bubbles*, which could not be, but by the entrance of some *External Matter*, causing them to swell and be extended: and the same is the case with *Water*, when it is turned into a *Vapour*.

III. An Objection rais'd from the Rarefaction of Water.

You will say, that in this case of a *Vapour* we perceive indeed that *Extension* is increased, but no access of any new *Matter*: Wherefore it is without ground to say that *Rarefaction* is performed by the addition of some other *Body*.

IV. Answer.

I answer, that in a *Vapour* there is no more *Extension* or *Quantity* perceived, than there was in the *Water* before its *Resolution*, because in this change nothing else happens but a *Solution*, *Division* and *Separation* of those parts, which before were more closely joined together; For he who at a distance beholds the *Vapours* that rise from *boiling water*, takes them to be a continuous *Body*; but if he take a nearer view of them, he will find them to be nothing else, but a crowd of innumerable small *Particles*, which separate and come between many other *Heterogeneous Bodies*. Wherefore where we find any *Body* dilated, we must conclude that it is by the access of some new *Matter*.

V.

But what kind of little Bodies are these, which enter the Pores of *Rarefied Bodies*, and which are expelled when they become close and hard again?

I answer that they are the same in *Substance* with those *Bodies* which are seen and felt by us; save only that they are more *subtil* and fluid, and so are fit to penetrate and fill the *Pores* of other *Bodies*. For according to our *Hypothesis*, there are some *Particles* in the *Air* and other *Bodies* so subtil, as to be able to pierce *Gold*, *Diamonds* and the most *Solid Bodies* that are.

You will say, that we do not find that the *Pores* are dilated in *Rarefaction*, nor that any New *Bodies* enter into them. But to this I answer, that all *Bodies* do not affect our *Senses*, by reason of their extream littleness. We know that a *Vine* in the Spring grows, and becomes extended to a further Length; which *Extension* could not be, but by an addition of *Bodies*, which dilate and stretch out the *Substance* of the *Vine*. And yet no *Man* ever perceiv'd these *Bodies*. We never saw the *Air*, and yet know that it is extended throughout the whole *World*. Wherefore neither in *Rarefaction* are we to deny *Bodies* to enter into the *Pores*, because we do not see them; but are to judge of what happens in these little *Bodies*, by what we see happens in the greater.

From this Explication of *Rarefaction* it is evident, why *Metals* and other *Hard Bodies* are not rarified without difficulty, but soft *Bodies* very easily, because the parts of them are readily separated and admit other *Bodies*, whereas hard *Bodies*, as *Iron*, &c. are not without great violence dissolved, and by that means hinder other *Bodies* from entering between their parts, wherein the Nature of *Rarefaction* doth consist.

You'll say that in *Rarefaction* not only that *Body* is rarefied whose *Pores* are dilated; but also all the subtil *Matter* that enters them, which cannot be without the introduction of other *Bodies*, and these again by the Introduction of others, and so to infinity, which is not to be admitted in *Natural Causes*.

I answer, there is no inconvenience to say that *Bodies* that have *Pores*, become rarefied by the Intromission of others, and these again by the Intromission of other lesser *Bodies*, so we do but admit that there are some *Bodies*, which because they have no *Pores* cannot receive other *Bodies*, and that there are such is not to be doubted, especially by them who hold *Quantity* to be indefinitely extended: For they must acknowledge that the *Parts* of *Matter* may by *Division* be made so small, that they cannot be further divided but by our *Thought*.

You'll say that the more loose or *Rarefied* a *Body* is, the more *Pure* it is also; as the *Air* is, when it is free from *Clouds* and *Vapours*: But now the *Purer* any *Body* is, the less it admits the mixture of any *External Bodies*; therefore *Rarefaction* is not made by the Introduction of other *Bodies*.

The Major of this Argument is to be deny'd; for *Pure* and *Rarefied* are not one and the same thing: That is *Pure* which is free from any mixture of *foreign Matter*: As the *Air* is said to be pure, when it is not obscur'd by *Clouds* or *Exhalations*. But a loose or *Rarefied Body* involves the mixture of *External Bodies*, and cannot be understood without it; as a *Sponge* that is swell'd with the Intromission of *Water*.

The ordinary Cause of *Rarefaction* is *Fire*; for the subtil *Particles* whereof it consists, being in continual *Motion*, easily enter the *Pores* of other *Bodies*, and dilate them. Hence it comes to pass that *Water*, which hath long boiled over the *Fire*, is more easily congeal'd than cold *Water* newly taken out of a *Well* or *River*, because the most subtil parts of it, which by their *Agitation* and *Motion* hinder'd *Congelation*, are evaporated in the *Boiling*. Neither are *liquors* only, but *Metals*, and other solid *Bodies* somewhat distended by *Heat*. Thus we find that melted *Metals* swell somewhat;

VI. There are Bodies that are not perceptible by the Senses.

VII. Why Metals are not rarefied.

VIII. It is not necessary that all the Parts of Matter be rarefied.

IX. There are some Particles that do not admit Rarefaction.

X. The Distinction between a Pure and a Rarefied Body.

XI. Answer.

XII. Fire is the ordinary Cause of the Rarefaction of Bodies, whether they be liquid or solid.

and that it is common with *thread* dipt in *Brimstone* to cut off *Glasses*, because the Parts of *Glass* being put in *Motion* by *Heat*, require a larger *Room*, which they cannot obtain, without driving away the parts that are continuous to them.

XIII. From what hath been said it is evident First, that the *Rarefaction* of *Air*, *Smoke*, *Vapor* and such like *Bodies*, are nothing else but a separation of the *Terrestrial Particles*, caused by a swift *Motion*, and the ingress of New *Cæstial matter* into the Spaces left by them. And that the *Condensation* of them, consists in a more intimate union of the said *Particles*, caused by the decrease of *Motion* or *Heat*, the Intervals whereby they were separated growing lesser, or being taken away, which when ever it happens, the *Body* thereby becomes so close and compact, that it cannot be made closer.

XIV. Secondly, we may infer hence that a greater or less *Extension* in *Bodies* that are rarefied and condensed, doth not belong to the *Essence* of a *Body*, but is only a new *Modification* of it, which supposeth a change of *Figure*, and the presence of another *Body* filling the *Pores* of it.

CHAP. XI.

Concerning the Heaviness and Lightness of Bodies.

I. **H**earviness and Lightness are the Qualities of *Bodies* with respect to their aptness to move upwards and downwards, in the *Sphere* of their *Gravitation*. Where by the name of *Apiness*, we are not to understand any *Inclination* or *Active Principle*, but only such a disposition of *Parts* which is capable of receiving the force of *Heaviness* or *Lightness*. And by the *Sphere* of *Gravitation*, I understand the whole space comprehended between the *Center*, or that which is lookt upon to be the middle, and the uttermost bounds of the cause of depression. Which *Sphere* is not only to be fixed about the *Earth*, but also about the other *Planets*, which being much of the same nature with our *Earth*, it follows, that the union of their *Parts* proceeds from the same or a like cause to that which keeps the *Parts* of the *Earth* together.

II. The *Peripateticks* hold *Heaviness* and *Lightness* to be innate *Qualities*, proceeding from the *Form* of *Bodies*, for their *Conservation*. Accordingly they say that *heavy things* tend downwards, from the forefaid *Appetite* they have to be preserved in the *Center*, and so be moved by a certain *Law* of *Nature*, whereby all things are disposed in their proper places, or by a *Motion* impressed by the *Author* of *Nature*. But this *Opinion* is grounded on a false *Hypothesis*. For, First it supposeth the *Earth* to be the *Center* of the *World*. Secondly, that *Bodies* that are put in *Motion* tend to *Rest*, tho' it be certain that nothing tends to its own destruction. Thirdly, that *Heavy Bodies* are preserved in the *Center*. Fourthly, that there is an *Appetite* or desire of this *Preservation* in *inanimate* things, when it is apparent that a desire is only competent to *living Creatures*.

III. Others, amongst whom is *GASSENDUS*, hold that *heavy things* tend downwards by the *Magnetick Virtue* of the *Earth*, which draws them down to it. But this opinion also is built on a false

supposition, in that in the *First* place it takes for granted an attractive *Motion*. Secondly, in that it supposeth the *Loadstone* to draw *Iron* to it, by its out-flowing *Particles*, which is not so, as will appear hereafter when we come to speak of *Magnetick Operations*. Thirdly, the *Magnetick Virtue* is communicated by the *Poles*, and *Lines* parallel to the *Poles*; whence it must follow, that the greatest *Gravitation* would be under the *Poles*, or near them, less in the intermediate places, and least or none at all under the *Aequator*. Fourthly, a common *Loadstone* has greater force, than the *Earth* itself, at least with us; whence it must follow, that it would be of greater strength also to the drawing of *Heavy Bodies* downwards; and then a piece of *Iron* cast upwards, would not in a right *Line* descend to the *Earth*, but towards the *Magnet*.

The Third opinion is that of *Des Cartes*, who holds that *Heavy Bodies* are driven downwards by the *Cæstial Matter*. For the better understanding of which, we must in a few words explain his *Hypothesis* concerning the *Diurnal Motion* of the *Earth*. He supposeth therefore the *Earth* together with the *Atmosphere* to be pois'd in the midst of a little *Vortex*, which is whirl'd round from *West* to *East*; whence it necessarily follows by the *Rules* of *Motion*, that the *Earth* hanging in this *Fluid Body*, must be whirl'd about with the same motion, by the *Heavenly matter* running against its *Pores*: yet so as that the *Earth* in its *Motion* is not separated from the *Fluid Body* that compasseth it, but as it were swims in it. To illustrate this, let us suppose a *Wooden Bowl* in the midst of a *Vessel* with *Water*, if any one make the *Water* whirl round, that is, in the *Circumference* or near the sides of the *Vessel*, it is notorious that the *Bowl* will turn round likewise, by the *Particles* of *Water*, that dash against the outside of it; and in like manner, is the *Earth* with the *Atmosphere*, Whirl'd about by the *Cæstial circumfluent matter*, not by any motion of its own.

And forasmuch as the *Cæstial matter* being very solid and agitated, hath more agitation in it, than is required to the whirling about of the *Earth*, and is hindred by the *Earth* from continuing its motion in *Right Lines*; what will follow hereupon? It is evident from the *Laws* of *Motion*, that its *Motion* cannot perish, and therefore will pursue its course, what way it can best; that is, it will have a *Power* of rebounding upwards. Now we know that nothing can move upwards except something move Downwards at the same time; and accordingly that will move downwards, which hath not so strong a force of *Agitation*, which is the case of all *Earthly Bodies*, except something else should intervene and hinder it.

Any one may Experience this by filling some round *Vessel* with small *leaden Bullets*, and amongst them, some pieces of *Wood*, or any other *Matter* lighter than *Lead*: If this *Vessel* be whirl'd round swiftly about its *Center*, all the pieces of *Wood* which have less *Agitation* will be driven to the Middle by the *Leaden Bullets*, which with greater force recede from the *Center* of their *Motion*.

The same was lately experimentally demonstrated by a *Mathematician* at *Paris*, in a *Vessel* with *Water* agitated, into which if the *Powder* of *Sealing-wax* be cast, the little *Particles* thereof

IV. Des Cartes his opinion concerning the Heaviness of Bodies explained.

down-
wards of
themselves
but are
driven
down.

will be seen driven towards the sides of the *Vessel*, for that by reason of their roughness they are easily carried that way by the strong agitation of the *Water*. But when that agitation begins to cease, and the *Particles* of the *Water* are more softly moved, this *Dust* or *Powder* is driven to the midst. The *Cause* whereof is this, because as long as any *Agitation* is continued in the *Water*, its parts endeavour to recede from the *Center*, in which recess they force the particles of *VVax* towards the *Center*, and as it were appoint their place to them. Whence it appears, that *Bodies* are not of themselves carried, but are driven downwards by the *Matter* that surrounds them.

VIII.
A particu-
lar Explan-
ation of
the Heavi-
ness of
Bodies.

Figure 11.

But to the end that the *Action* of the *subtil Matter* may be more distinctly perceived, let us imagine all that is included in the *Circle* *ABCD* to be a *Mass* consisting of the *Earth*, *Water* and *Air*, the *Center* whereof is *E*, where the little *Circle* *FGHI* represents the *Earth*. Then let us imagine this whole *Mass* to be divided into many *Pyramids*, which with their *Extremities* reach to the *Center*, one whereof let be *AEB*. Having supposed this, we shall find first, that tho' all the several parts, which make up so many *Pyramids*, strive to withdraw from the *Center* *E*, yet can they not recede all at once, because there is no empty space about that *Mass* which they constitute, whither they might retire, and the subtil *Matter* hinders them from moving out of their place. Moreover we shall find that not one of these *Pyramids*, by Example, *AEB*, can recede whole and entire, enlarging it self in its extremity *AB*, and driving away from it the adjoining matter, and making it to come closer to the *Center*: Because the *Pyramids*, which surround the *Pyramid* *AEB*, do with a like endeavour recede from the same *Center*, and for which they have no less force, than the *Pyramid* *AEB*. But if we suppose some *Terrestrial Body*, as *L*. in the *Pyramid* *AEB*. without any in the Neighbouring *Pyramids*; we shall easily conceive, that it will have less force to recede from the *Center*, than the others, that are about it, by how much the *Body* *L* hath less force than the subtil *Matter*, whose place it takes up. Whence we must conclude that the *Matter* of some of the *Pyramids* will recede from the *Center*, and drive the *Body* *L* nearer to it, after the same manner, as they who hold all *Bodies* to be *Heavy*, suppose the *Water* to lift up a piece of *Cork*, and force it to the *Surface* of it.

IX.
Wherein
the Heavi-
ness of
Earthly
Bodies doth
consist.

The *Heaviness* therefore of *Earthly Bodies* consists in this, that the *Globuli* of the *Caelestial Matter*, being whirled about in their *Vortices*, endeavour continually to recede from their *Centers*, about which they are turn'd; but forasmuch as they cannot exert this their strife and Propension, except in their mounting upwards, they thrust down other *Bodies* into whose place they may succeed: Wherefore they must needs at the same time depress the *Particles* of *Earthly Bodies* that are in the *Air*, as well because of their *Resistance*, as because of the want of *Caelestial matter* in their *Pores*; both which hinder the *Earthly Particles* from having so great a Propension of receding from the *Center* of the *Earth*, as the *Heavenly matter* that every way surrounds them, hath. Wherefore the *Lightness* of the *Caelestial Matter* is nothing else but the force or strife it hath to recede from the

Earth; as the *Heaviness* of the parts of the *Earth* consists in their being such, that this highly agitated *Matter* exerts its power upon them in thrusting of them downwards.

When it is said, that the *Heaviness* of *Bodies* is caused by the *Heavenly matter*, we do not only by the understand the *Globuli* of the *Second Element*, but also the *Matter* of the *First* mixed with it: For this being extremely agitated, exceeds the *Matter* of the *second Element* in the force it has to drive *Bodies* downwards. Neither are the *Particles* of the *Air* to be rejected from having any share in this performance, seeing that they accompany them in their Course, and being joyn'd with the *Globuli* of the *second Element*, exert their force, and do not a little conduce to the driving down of *Bodies*.

We may therefore alledge a double Cause of the Descent of *Heavy Bodies*; the one *Primary*, viz. The Cause the *Heavenly Matter*, by its strife upward, not of the Descent of *Heavy Bodies* is *Two fold*. from any innate Appetite, but to continue its *Motions* according to the *Laws* of Nature. The other *Secondary*, viz. any *Earthly Body* carried upwards, whether it be obsequent to the *Motion* of the *Heavenly Matter*, as *Air*, *Vapours*, *Exhalations*, and any other lesser *Particles*; or whether it be driven upwards by any other Cause: So *Smoke* agitated by the *Fire*, hath a Power of depressing the *Air*: Thus when any one casts a *Stone* upwards, he at the same time thrusts down as much *Air* in its place; which *Air* because of the *Heavenly Matter* intermix'd with its *Particles*, and its *Agitation* thereby caused, as likewise its *Elastic force*, will first resist the *Motion* of the *Stone*, next hinder its *Ascent*, and at last depress or thrust it downwards.

You will object, if the *Heaviness* of *Bodies* depend on both these Causes, it will follow that all *Bodies* would be of the same *Weight* or *Heaviness*, since both the *Heavenly Matter*, and the *small Bodies* carried upwards, do press them after the same manner.

I answer, that the Nature of *Heaviness* and *Lightness* in *Bodies*, consists herein, that as much *Heavenly Matter* as there is in any *Body*, so much cause of *Lightness* they have, which being subtracted, all the rest will come under the notion of *Gravity* or *Heaviness*. As for Example, *Water* is *Heavier* than the *Air*, because if you subtract the *Aethereal* interspersed *Matter* from them both, there remains more *Earthly Matter* in the *Water*, than in the *Air*. So that this may be laid down as a General Rule, That the more *Heavenly Matter* there is in any *Body*, by so much the *Lighter* it is, that is, the more apt it is to be carried upwards; and the less there is of it, the *Heavier* that *Body* is, that is, the apter to be thrust downward.

Thus *Solid Bodies* are more *Heavy* than *soft*, because they have more *Matter* of their own, and *Solid Bodies* therefore are called *close Bodies*, having less *Pores*, which can only admit the *Subtil Matter*, or the *Globuli* of the *second Element*, such as are *Gold*, *Silver*, *Quicksilver* and *Steel*. But *soft* or less *Solid Bodies*, contain more *Heavenly Matter*; and have greater *Pores*, and are therefore *Looser Bodies*, such as *Wood*, &c. Wherefore tho' all the *Heavenly Matter*, with all its force strives to recede from the *Center*; yet the more close and compact *Bodies* have a greater Power to resist, and do more difficulty recede from the *Center* of their Motion.

Motion; whereas *Bodies* of a more loose Texture, have more of the *Heavenly Matter* than of their own, and a greater Propension of receding, and therefore do less resist the *Agitation* of the *Heavenly Globuli*, or little round *Bodies*.

XIV.
Whence
proceeds the
variety of
Heaviness.

This is the reason why the *Water* is placed on or above the *Earth*, and the *Air* above the *Water*; because the parts of the *Earth* being more solid than those of the *Water*, and the parts of the *Water*, than those of the *Air*, they are more strongly driven down to the *Earth*, by the *Ethereal Matter*; much after the same manner, as *Corn*, that is mixt with *Chaff*, is by the *Agitation* of a Fan cast off further, leaving the *Chaff* behind it.

XV.
How it
comes to
pass that
a Stone to-
wards the
end of its
motion
comes down
faster than
at the Be-
ginning.

It may be objected against this, that the *Globuli* of the second *Element*, do strike with a greater force against *Bodies*, before they begin to descend, than in their falling down; and therefore they ought to thrust them down more swiftly at the Beginning of their *Motion*, than towards the end of it; which notwithstanding is contrary to experience; for a *Stone* moves swifter towards the end of its *Motion*, than at the Beginning; and therefore the Descent of *Earthly Bodies* is not to be ascribed to the *Subtil matter*.

XVI.
Answer.

I answer, that the reason of the Difference of the *Stones Motion* is this, because the *Stone* in its Descent, retains the Force of the foregoing *Motion*, and besides receives an increase from the Impulse of the *Subtil Matter* that follows it; for the *Subtil Matter* is swifter than it. Now the cause why *Descending Bodies* are less forceably driven down by the *Subtil Matter*, towards the End, than at the Beginning of their *Motion*, is this, because there is not so great a difference of swiftness between their *Motion*, and that of the *Subtil Matter*.

XVII.
How Bodies
can move
in the Air
seeing they
are prest on
all sides by
the Fluid
Matter.

But you will say, seeing that the *Bodies* that are surrounded with *Fluid Matter*, are equally prest upon on all sides, they are not like to move at all, but will remain hanging in the *Air*. I answer, that this indeed would follow, in case the *Fluid Body* be simply consider'd as *Fluid*: But since the case is otherwise here, and that the whole *Fluid Matter*, because of the Resistance of the *Earth*, strives to get free from its Neighbourhood, this is sufficient to determine the *Motion* of *Gross Bodies* downwards, as being much more unfit for *Motion*, than the *Heavenly Matter*, and *Fluid Bodies*, in which they are carried, are.

XVIII.
This opinion
doth most
appositly
explain all
the Phæno-
mena of
Gravity.

How Appositely this opinion solves all the *Phænomena* of *Heaviness* will appear from the following particulars.

First, This force will exert it self every where throughout the *Earth*, because the *Celestial Matter* will find resistance every where, that is, it will be determined upwards as well towards the Poles, as about the *Aequator* and *Lines Parallel* to it.

Secondly, All things fall down perpendicularly to the *Horizon*; because the *Celestial Matter* hitting against the *Earthly Particles*, will rebound back with infinite variety, because of their different meeting, Figure and Situation of their Parts, that is on every side equally, at least to *Sense*; and consequently will make all those things *Fluid*, which are fit to follow its motion; and whatsoever is impuls'd by the *Fluid Mass*, will fall perpen-

dicularly, because it is with equal force prest on all sides.

Thirdly, The *Sphere* of Gravity becomes terminated, where this force of receding, because of the too great distance, is not strong enough.

Fourthly, Here we find the reason, why every *Planet* hath its *Sphere* of Gravity, because nothing else is required to this, but its swimming in the midst of *Fluid Matter*.

From all that hath been said it is obvious, that *Heaviness* is nothing else, but the strife or effort wherewith a *Body* is pulst towards the *Axis* of the *Earth* by other *Bodies*, which strive to recede from it. That *Absolute Heaviness* is that by which every *Body* is pulst downwards by a Column of the second *Element* equal to its own; and that *Respective Heaviness* is that which belongs to a *Body*, only with respect to other *Bodies*.

XIX.
Heaviness
is either
absolute or
Respective.

CHAP. XII.

Concerning Place.

HAVING examin'd the *Rarefaction* and *Condensation* of *Bodies*, and inquir'd into the Reason of their *Heaviness* and *Lightness*, it remains now to consider why *Bodies* are said to be in a place, and what order they keep amongst themselves. Now *Place* is nothing else, but a respect of the Situation of a *Body*, which it hath amongst other *Bodies*, to which it is either near or far from. So that when we say that a *Body* is in a place, we only intimate thereby that it hath such a *Magnitude*, *Figure* and *Situation* amongst other *Bodies*, with respect to its nearness to them or remoteness from them.

i.
What
Place is.

True it is, that the *Common People* distinguish *Place* from a *Body*, and suppose *Place* to be the *Space* that receives a *Body*, and contains it. For they persuade themselves that *Place* is a kind of *Space* which Exists before the entrance of the *Body*, and remains after it is withdrawn. But this conceit ariseth from a *Popular error*, by which they imagine that there were some extended empty *Spaces*, before that there were any *Bodies* in Nature, and which were afterwards to receive them. As some *Philosophers* now since the *Creation* of the *World* fancy that there is a kind of empty *Space* beyond the Bounds of the *World*, which they call *Imaginary Space*, because it hath only *Extension*, without containing any *Body* at all.

ii.
What
Place is ac-
cording to
the opinion
of the Com-
mon People.

But these *Philosophers* speak very improperly, since whatsoever is extended in *Length Breadth* and *Depth*, and wherein *Parts* can be assigned, by the intervals whereof *Bodies* may be said to be near or far off from one another, cannot be said to be a thing *Imaginary*, but a true and real *Body*. For the Nature of a *Body* consists in *Extension*, and the Idea of *Extension* is the same with the Idea of a *Body*. Seeing therefore the *Imaginary Space*, as they call it, hath *Length*, *Breadth* and *Depth*, it must needs be a *Body*. Whence it is apparent how improperly they speak, who tell us that *Bodily things* are in a *Space*; for since every *Space*, because of its *Extension*, is distinguish'd from the *Dimensions* of the *Body*, that is in the *Space*, and that Penetration of *Dimensions* is impossible, should we suppose a *Space* to receive a *Body*, this would be a *Penetration* of *Dimensions*. Now *Bodies* are there-

iii.
Space is the
same with
a Body.

fore

fore said to be *impenetrable*, because they have their peculiar *Dimensions* which exclude any other, and do not suffer them to be contain'd in the same place; and since a Space is measur'd with the same *Dimension* as a *Body*, therefore a *Body* cannot be said to be in a *Space*.

IV. But you'll say, how then is a *Body* said to be in a *Place*, if a *Place* be extended as well as a *Body*, and that one of them exclude the other? I answer that a *Body* is said to be in a *Place* by the *Situation*, *Magnitude* and *Figure* it hath amongst other *Bodies*; so that we must not conceive any thing as extended, but only the *Body* that is in the *Place*, and all the *Space* or *Expansion* that is conceiv'd to be there, must be attributed to the *Body* only. For to speak properly, *Place* or *Space* is nothing else, than something that is extended in *Length Breadth and Depth*, which is the same with *Matter*; neither can it be distinct from it, but by our way of conceiving. Wherefore when a *Body* is said to take up a little or great *place*, the meaning of it is only this, that such a *Body* hath a greater or less *Extension* amongst the *Bodies* that surround it. This gave occasion to St. AUSTIN to say *Epist. 52. ad Dard. Take away Spaces from Bodies, and they will be no where, and being no where they will not be at all.*

V. Wherefore there is no Real Difference between a *Space* and a *Body*, but only according to our way of *Thinking*, viz. because we consider the *Extension* of *Space* as *Common* and *General*, but the *Extension* of a *Body* in a *Space*, as *Individual* and *Singular*. As for Example; when a *Stone* is taken up out of its *place*, we suppose its *extension* to be removed also, because we look upon it as *singular* and *inseparable* from it; but yet we conceive that the *Extension* of the *place* in which the *Stone* was, still continues, and is the same, tho' the *Stone's Place* be now taken up by another *Body*, viz. *Wood, Air, &c.* Because this *Extension* is consider'd in *General*, and suppos'd to be one and the same, whether of the *Stone, Wood, Air*, or any other *Body*, provided it be of the same *Bigness*, and have the same *Situation* amongst those *Bodies* that determine and bound that *Space*. Wherefore it is evident that the *Inward Place*, which is taken up by any *Body*, doth not differ from the *Body* it self, no more than the nature of the *Genus* or *Species* differ from the *Individual*. And tho' a *Body* may be said to change its *Place*, this is not to be understood of the *Inward*, but only of the *outward Place*, that is, of the *Superficies* of those *Bodies* that surround it, to the different parts whereof, it may be diversly apply'd.

VI. This will be more evident by distinguishing *Place* into *Inward* and *Outward*; *Inward Place* is nothing else but the *Matter* it self extended in *Length Breadth and Depth*, or the *Body* it self: *Outward Place* is the *Superficies* of the *Body*, which immediately surrounds the thing *Placed*. And this *Place* is neither a *Body*, nor any thing of a *Body*, but only a *Mode* of it, or the limit wherein the *Body* is contained. For by the name of *Superficies*, no part of the *Ambient Body* is understood, but only the *Boundary* or limit, that intervenes between the *Ambient Body* and the *Body surrounded*, which is only a *Mode*. Or we understand thereby a *Superficies* in common, which is no more the part of one *Body* than of another, only is suppos'd al-

ways to be the same, because it retains the same *Magnitude* and *Figure*. For tho' every *Ambient Body* together with its *Superficies* be changed, yet is not the thing it surrounds therefore supposed to change its *Place*, provided it keep the same *Situation* amongst other *Bodies*, which are consider'd as *immoveable*. Thus we do not say that a *Tower* changeth its *Place*, when the *Ambient Air* leaves it, because we suppose that still other *Air* comes in the room of it, and accordingly the *Superficies* is neither a Part of the *Body* containing, nor of that contained, but only an intermediate term or limit, which indeed is nothing else but a *Mode*.

Moreover it is evident, that, if there were any such *Imaginary Spaces*, the *Bodies* contained in them could not be said to be in a *Place*, forasmuch as in them there is no *outward Place*, neither can any parts be assigned to them; and therefore a *Body* cannot be said to be *here* or *there* in them, notwithstanding that it really takes up a *Place*. But a *Body* being consider'd as something consisting of *Parts*, and consequently contiguous to other *Parts* of *Bodies*, according to this *Notion* there can be no *Body*, which hath not a determin'd *Place*, with respect to its *nearness* or contiguity to some other *Body*, by which its *External Place* is designed.

The difference therefore between *External Place* and *Space* is only this, that *Place* more expressly denotes the *Situation* of a *Body*, than its *Magnitude* or *Figure*; whereas *Space* refers rather to these two latter. For we often say that a thing comes into the place of another, tho' it be not exactly of the same *Bigness* or *Figure*; but at the same time deny it to take up the same *Space*. And so whenever the *Situation* is changed, we see the *Place* is changed, tho' the same *Bigness* and *Figure* do remain. And when we say that a *Thing* is in a *Place*, we mean nothing more than that it hath such a *Situation* amongst other *Bodies*; and when we say that it fills such a *Space*, we understand thereby its being of such a determinate *Figure* and *Magnitude*. All which will be further cleared by the following *Rules*.

When a *Place* is said to be equal to the thing placed, this is either understood of the *Inward Place*, and then it is the same, as to say, that a *Body* is of such *Dimensions*, or equal to it self; or else of the *Outward Place*, and then it imports, that the bounds of the *Ambient*, do exactly answer to the *Superficies* of the *Body* surrounded or contained, but not as if they had equal *Dimensions*: in like manner as the *Rule* is said to agree with the thing ruled, tho' it do not agree with it every way, as to its threefold *Dimension*.

Two *Bodies* cannot be in the same place at once, that is, they cannot at the same time have the same respect of distance to the same *Bodies*; for if so, they must penetrate each other, and there would be a *Multiplication* of *Extension*, without supposing any new *Parts*, which is contradictory to the *Notion* of a *Body*.

One *Body* cannot be in two *Places* at the same time, that is, it cannot be placed between these and other contiguous *Bodies* at the same time, because a *Plurality* of *Places* infers a *Plurality* of *Bodies*; for *Place* is only the *Mode* of a *Body*: Or thus: *Space* is not distinct from a *Body*, therefore the *Body* that is in diverse *Spaces*, is both another and the same thing at the same time.

Fourthly,

VII. A *Body* in the *Imaginary Space*, is neither here nor there.

VIII. The Difference between *External Place*, and *Space*.

IX. The First Rule.

X. Second Rule.

XI. Third Rule.

XII. Fourthly, a Body is said to change its Place when it changeth its respect to other Bodies; and forasmuch as we can have regard to different Bodies, the same thing may be said to change its Place, and not to change it, under a different regard; tho' most properly a thing is said to change its place, with respect to those Contiguous Bodies, that are considered as immoveable.

XIII. Whence it appears that the Inward Place of a Body, or the Space it takes up, consists in the Body it self, consider'd as bounded by other Bodies, which immediately touch it; and that the Outward Place consists in the first Surface of the Bodies that surround another Body.

CHAP. XIII.

The supposing of a Vacuum in Nature, implies a Contradiction.

I answer in the First Place, that this or the other Body may be taken out of a Chamber or any Vessel; but it is impossible that they should be without any Body at all. For where there is no Body, there is no Extension, where there is no Extension, there is no hollowness, capacity or interval, and without these there can be no Vessel or Chamber.

Secondly I say, that supposing all intermediate Bodies to be taken away, the Chamber Walls would touch one another, because nothing would be between them; for we cannot conceive one thing to be distant from another, without some Middle thing to separate them; because distance is a Mode of Extension, and therefore follows a Bodily Substance, without which it can neither be, nor be conceived.

But you will say, that the Body which is conceived to be in the Chamber or Vessel, is something different from the sides that surround it, and therefore the one may be separated from the other by the Divine Power, forasmuch as we clearly and distinctly understand the one, not to be the other.

I dare not say that any thing is impossible to God, or that he cannot make a Mountain without a Valley: But this only I assert, that God hath made my Mind such, that I cannot conceive how a Mountain should subsist without a Valley; or how Five and One should not make Six. And the same may be applied to that Space which is imagin'd to be between the Sides of a Chamber or Vessel, because the same cannot be conceived without extension. And since nothing can have no Properties, that Space cannot be said to be a Vacuum that is void of all Matter. Or if that should be, the sides of the Chamber or Vessel, must be suppos'd to touch each other. For if God should annihilate all the Air that is in a Chamber, there would be no Space left between the Walls; for if any Space be left, there must be Magnitude also; and if Magnitude, then Quantity; and if Quantity, Matter, and consequently a Body, because Space, Magnitude, Quantity, Matter and a Body are one and the same thing.

For what can be imagin'd more absurd than to assert that the distance of Bodies is owing to an Imaginary Space, or nothing, seeing that when the intermediate Body is taken away, all distance must of necessity be taken away likewise? Who will say that nothing can be measur'd, when it is evident, that not only Extension, but any other Propriety whatsoever, must be remov'd from Nothing? For if I may say that a Space (which is nothing) is of such a length, I see no reason why I may not as well ascribe other Properties to it, such as Hardness, Softness, &c. It remains therefore that Nothing cannot make a Distance between Bodies. For suppose we a Square Vessel ABCD, and the Hollow of it to be empty, I say that the same cannot be measur'd: For tho' if it be enquir'd by what thing the sides AB, DC are distinct from one another, it may be readily answer'd by the Straight Lines AD, BC. Yet I cannot return the same answer to him that enquires the distance between the opposite Angles DB: for if I should say they are kept at a distance by the Straight Line DB, how can this be true, seeing nothing at all is in the Vessel, and therefore no Length or Measure can be apprehended in it?

This Conclusion may be confirmed from the necessity there is of a Connexion of all the Bodies that do constitute the Universe, and that they be so joyned

VIII. First Answer.

IX. Second Answer.

X. To conceive a space without Extension, implies a Contradiction.

XI. If Bodies be taken away, all distance is taken away likewise.

XII.

There is a necessity for the Connexion of Bodies.

I. It cannot be denied but that the common way of Speech doth frequently differ from Truth, and that they are lyable to mistake, who mind words rather than their own Notions; as they seem to do, who by the word Vacuum, understand the absence of some Body, which ought to be in such a Place. As when they say, that a Vessel is Empty, which is not fill'd with Water, Wine, or the like; or a Purse is empty, in which there is no Money, and a Space empty in which there is no sensible Body.

II. But learned Men allow nothing to be empty, but what is devoid of any Body whatsoever; and therefore they commonly define it a Place void of Body, yet fit to be filled. This Vacuum is twofold, Disseminate or Coacervate.

III. A Disseminate or interspers'd Vacuum they call small Spaces, which are suppos'd interspers'd between Material Things.

IV. A Coacervate Vacuum, is a sensible Space void of Body, such as they suppose to be in a Pipe of Glass after the removal of the Quicksilver in the Torricellian Experiment.

V. That neither of these Vacuities can be found in the Universe, may be prov'd by many Arguments. First because every Space imports Extension, which is of the Essence of a Body; for it implies a Contradiction that nothing should have an Extension, and therefore there cannot be any Space, in which there is not a Corporeal Substance. For as we suppose a Body to be there, where we find Extension; so for the same Reason we must conclude, that a Body must be in a Space, because we clearly conceive Dimensions in it: So that it is not more impossible to conceive a Mountain without a Valley, than to conceive Space without Matter.

VI. Secondly, a Vacuum is defined to be A place devoid of Body: Now this also implies a contradiction, supposing the notion we have already given of place to be clear and distinct; for where there is no Body, neither can there be any Mode of a Body; yea, the very empty Space it self, will be no less in a Place, than any Body whatsoever, as is evident to him that considers it well: And what can be more unworthy for a Philosopher, than to accommodate this Idea to a Non-Entity, which altogether agrees to a Real Being?

VII. You'll say that God can take away all the Substance, that is contain'd between the Walls of a Chamber, and keep any other Body from entering it; upon which supposition a Vacuum must follow.

joyned together as not to be separable from each other. Which yet is not so to be understood, as as if there were such a Connexion, between this Chamber suppose, and the particular Air that is in it, that they cannot be separated from each other; for we see that this Air is driven out by the Wind, and that other comes into its place; but only thus much, that there is a necessary Connexion between this Chamber, and Quantity in General, forasmuch as there can be no Distance or Interval, but must be fill'd with some Body or other.

XIII.
Supposing a
Vacuity,
two Round
Bodies
would to-
tally touch
one ano-
ther.

The same may be farther prov'd from the Absurdity which would otherwise follow; because supposing a Vacuum, Round Bodies would touch one another after the same manner as Flat Bodies do, that is, totally. For those Bodies are said totally to touch each other, between which there is no intervening Medium; but betwixt two Round Bodies in a Vacuity there can be no Medium assign'd; therefore they touch with their entire Superficies. It is not sufficient for the solving of this, to say, that a Possible Substance mediates between them, because a Possible Substance cannot be an Actual Medium dividing and separating Bodies: For otherwise nothing in the World could be said to be united; since between the Parts of Bodies that are united there is some Possible Medium that may divide them.

XIV.
An Objection,
that
Distance is
nothing
else, but a
negation of
contact.

If you say that Distance is no Real Thing, because two Bodies may be conceiv'd to be distant, only by the Negation of their contact; and that it is not necessary for any thing to intervene between Bodies to make them distant from each other.

XV.
The Ob-
jection an-
swer'd, and
distance
prov'd to be
Extension.

I answer, seeing Distance is a Relation, which must be between more than one, it belongs to Opposition or Distinction, the Essence whereof consists herein, that one thing is not the other. But forasmuch as there is no Real Distinction, which hath not its Foundation, because nothing can have no affections, therefore the Foundation must consist in something that is different from the things between which there is a Distance, which since it cannot be Spiritual (for then it would be void of Extension) it must be Material or Corporeal. For it would be a very improper Answer to the Question, why London is at a distance from Paris, to say, Because they do not touch one another; for this would be the same thing as to say, that London and Paris are at a distance, because they are not near one another, which is to explain an unknown thing, by another thing equally unknown. We conclude therefore, that Distance, besides the Negation of Contact doth necessarily include Extension, by means whereof remote Bodies are said to be distant from one another.

XVI.
Nature
doth not
abhor a
Vacuum.

Hence it appears how falsely the Schools assert, that the motion towards mutual Contact, is prevalent above all others, as being ordained for the Conservation of the Universe, by the avoiding of a Vacuum in Nature: For how can Nature be said to avoid a Vacuum, seeing that an Empty Space implies a contradiction? For those things are us'd to be forbid by the Laws, which may be done, and not such whose being implies a contradiction.

XVII.
Water con-
densed in a
close stopp'd
Vessel, doth
not leave a
Vacuity.

All other Arguments made against this opinion are of no force at all against us, who assert the Extension of Space, not to differ from the Extension of a Body, forasmuch as it includes Length, Breadth and Depth. What they object of a Vessel fill'd with

hot Water, which tho' it be close stopp'd, yet the Water that is in it, is reduc'd to a less Space, and consequently must leave a Vacuum, is of no Moment at all, because the Space which they imagine to be void, is fill'd with the subtil Matter penetrating the Pores of the Vessel; for it is a meer vulgar Errour, to believe those things to be Empty, which we do not see to be fill'd with Bodies.

It is evident from what hath been said, that a Vessel doth not contain more Matter when it is fill'd with Gold, than when it is fill'd with Air, forasmuch as there is as much extension in the Air as in the Gold. A Vessel indeed may contain more Gold, than it can of Pumice Stone, because in this latter there are many Pores which are fill'd by the Air, and not with its own Substance.

XVIII.
A Body is
no less fill'd
with one
Body than
with ano-
ther.

CHAP. XIV.

Of the Vulgar and Philosophical Definition of Motion.

BY the name of Motion we only understand that which is Local, as being the only Motion that is found in Nature, and to which all the rest are to be refer'd. For tho' ARISTOTLE Lib. 8. *Physic. cap. 7.* reckons up three kinds of Motion, viz. Motion in Magnitude, in Affection, and in Place; yet he asserts that the latter of these must needs be the first of all Motions, and concludes, that Generation and Corruption, Accretion and Diminution, and last of all, Alteration, cannot be without Local Motion. For what else is the Motion of Generation and Corruption, but Local Motion, whereby the sensible and insensible parts, are fitly, or unfitly joyned together, according to the Essential Constitution of Bodies? So likewise in Accretion and Diminution there is a Local Motion, whereby several parts are united to the Body growing; or whereby those that have been joyned with it, are now separated from it. And as to Alteration, we find for Example, that Calcification or Heating is perform'd by Local Motion, it being nothing else but the swift agitation of the parts of some Body; as in Refrigeration or cooling, the said parts are more slowly moved, or have no Motion at all. Tho' indeed if we would speak strictly, all the other Species of Motion that are commonly reckon'd up, are rather changes made by Motion, than Motions.

Wherefore seeing that all these kinds of Motion, are only certain differences of Local Motion, denominated from their various effects of Generating, Corrupting, Encreasing, Diminishing and Altering, we should multiply Entities in vain by going about to establish any other sorts of Motion, besides this.

But that we may the more clearly discover the nature of Motion, we will first enquire what is understood by this Word, according to the vulgar acception of it, and then come to explain the true and Philosophical Notion of it.

The Common People by Motion, understand the Action whereby some Body is remov'd from one place to another. This is that which they do mean by Local Motion. And therefore they suppose that a Body may at the same time be moved, and not be moved, as a Master of a Ship, who is said to be moved, if the Shoar be consider'd as immoveable; and not to be moved, with relation to the Stern of the Ship.

I.
Local motion
that is found
in Nature, and
to which all the
rest are to be
refer'd. For tho'
ARISTOTLE
Lib. 8. *Physic. cap. 7.*
reckons up three
kinds of Motion,
viz. Motion in
Magnitude, in
Affection, and
in Place; yet he
asserts that the
latter of these
must needs be the
first of all Motions,
and concludes,
that Generation
and Corruption,
Accretion and
Diminution, and
last of all, Alteration,
cannot be without
Local Motion.

II.
All other
Motions are
denominated
from their various
effects of Generating,
Corrupting, Encreasing,
Diminishing and
Altering.

III.
Motion is
understood by this
Word, according to
the vulgar acception
of it, and then
come to explain the
true and Philosophical
Notion of it.

IV.
The Common
People by Motion,
understand the
Action whereby
some Body is
remov'd from one
place to another.

V.
This is that which
they do mean by
Local Motion.

VI.
And therefore they
suppose that a
Body may at the
same time be
moved, and not
be moved, as a
Master of a Ship,
who is said to be
moved, if the
Shoar be consider'd
as immoveable;
and not to be
moved, with
relation to the
Stern of the
Ship.

Ship where he sits. Secondly, by this action the Common People imagine, that a greater force is required to produce Motion than Rest. Which Judgment they make, because they find that the Command of their Will is required to the moving of their own Bodies, whereas they Rest by their own Weight, without standing in need of any other thing to stop them. But they may be easily convinc'd of their error by putting them in Mind, that very often there is as much action required to stop the Motion of Bodies, as there is to move them. For there needs as much force to stop a Stone that is tumbling down from a Mountain, as to tumble down a Stone, that lies still on the top of it.

V. There are five things to be consider'd in every Motion; the mover, the moved, the Term from which, and the Term to which, and Succession. The mover is that which doth move; the moved, is the Body that is moved by the Action of the mover; the Term from which, is the Neighbourhood of those Bodies which it quits; and the Term to which, is the Neighbourhood of those Bodies to which the Body comes; and Succession is that progress whereby the thing moved is continually in a different manner apply'd to the various Parts of Ambient Bodies.

VI. Now to the end that this Progress or Succession may be the better understood, we are to observe, that Motion may be consider'd three manner of ways: First, as it proceeds from the mover, as by example, from a Man who throws a Stone, and so in the mover it is call'd an Action. Secondly, as it is receiv'd in the thing moved, at the first moment of its impulse, whilst it is yet joyned to the mover, Ex. Gr. in the Stone, which a Man casts, and so it is a Passion. Thirdly, forasmuch as it is in the Body moved, separated from the mover, as in a Stone, when it is carried through the Air, and so it is a certain Mode or state opposit to Rest; and in this last Sense Motion is here taken: And accordingly Motion is defin'd to be, the Translation of a Definite Body from the Neighbourhood of Bodies that immediately touch it, to the Neighbourhood of other Bodies. Or it is the successive application of one Body, to the Parts of Bodies immediately touching it.

VII. It is call'd a Translation in the first place to shew that Motion is not a thing subsisting, but only a Mode of Substance: For a Body is otherwise when it is moved than when it rests. Secondly, to distinguish it from the Action that translates it, or the Cause of its Motion: For that Rule of Logick is sufficiently known, that the cause cannot be the Genus: For we do not say that a sound is the motion of the Air, but a Quality arising from the Motion of the Air. And in like manner we must not say that Motion is an Action, but a Translation caused by some Action or force, which will more clearly appear, when we shall shew hereafter, that the Moving force is not a Mode of the Matter, but the Action of God.

VIII. It is said to be the Translation of one Body out of the Neighbourhood of Bodies Immediately touching it, &c. not from one place to another, because by the word Place nothing of certainty is signified, forasmuch as with respect to diverse things, the same thing may be said to change its Place, and not to change it. So he that sits in a Ship, changes his Place with regard to the Shoar, which he leaves,

and does not change it regard being had to the parts of the Ship. Now by defining Motion to be a Translation from the Neighbourhood of contiguous Bodies, we denote that the Body is moved by its own proper Motion: So that tho' many common Motions, may be at the same time attributed to the same Body, yet one of these only is its Proper Motion, viz. that whereby it is separated by Bodies contiguous to it. As he that sits in a Ship, tho' he participate of the various Agitation of the Ship, yet is he not moved with any proper Motion of his own, because he abides fixt and unmov'd as to the contiguous Bodies that are about him.

By one Body is understood all that which is transferred; tho' it may consist of many parts, which have other Motions. Because these Motions are not really distinct; it being a difficult thing to understand so many Motions together: As for Example, when the Body of an Animal is moved, his Tongue, Hands, Blood, and Spirits are moved also; all which Parts have their particular Motions, besides the common Motion of the whole Body, which they partake of.

But the Difficulty is since there is no Vacuum in Nature, and that all the Bodies of the Universe, have proportionate places which they fill up, how can Bodies be moved when there is no empty space to admit them?

I answer that local motion may very well be performed notwithstanding the absolute Plenitude of the Universe, not by means of any Compression and Dilatation of the Fire (as the Peripateticks tell us) but by a circular yielding of Bodies; so that when a Body is moved, it thrusts the next Body in its way out of the Space, which it enters into, and that again thrusts out another, and so to the last; which enters upon the place which the first Body has left, at the same instance that it leaves it. This we see in a round Pipe fill'd with Bullets, that the first of them cannot be moved, except the last by the impulse of the intermediate ones do succeed into its Place. Thus our Philosophy rejects all similiar, Magnetical and Electrical Attraction, and every motion which is not performed by the impulse of Bodies, according to the Rules hereafter to be mentioned.

So that whenever this Circular Motion of Bodies is hindred, there can be no Motion at all; as may be seen in a Tasting Pipe used by Wine Coopers, represented by ABC, the upper Orifice A, being shut, and the inferior C, open. For tho' the liquor that is contain'd in it be much heavier than the Air, that is without; yet because the Air that is prest by the liquor ready to run out of the under Orifice C, cannot recede, because the upper Orifice A, is stop't from receiving the Air that should succeed instead of the liquor running out of C, therefore the liquor continues in the Pipe as finding no place to receive it, because the circular Motion of Bodies is hindred, by the stopping of the upper Orifice of the said Pipe.

Thus may we see that the Motion of Bodies may very well be explained without penetration of Dimensions. And if it chance to happen, that the Circle through which the Body is to pass be unequal, that is narrower in one part than another, it must necessarily follow that the Body must be more swiftly moved where its passage is narrow, and so compensate the straitness of the place, by the celerity

IX. What is meant by one Body in the Definition.

X. How Bodies are moved, since there is no Vacuum into which they may be received.

XI. Answer.

XII. How it comes to pass that liquor doth not run out of a Tasting Pipe.

Figure 4.

XIII. A Body is more swiftly moved through a narrow Passage.

city of its *Motion*. For it is one of the *Laws* of *motion*, that when any liquor passeth from a large place to a straiter, the swiftness of its motion encreaseth proportionably to the decrease of the wideness of its passage. This may be shewed by many examples: Thus *Winds* are more vehement in a narrow passage, than in a wide *Street*; a *Bellows*, tho' but leisurely compressed, sends out the *Air* through the *Nozzle* with great swiftness and force; and *Waters* otherwise gliding gently, when they pass through *Sluces* run violently; and this because it is necessary that the whole *Circle* of *Bodies* should move all at once.

XIV. This opinion is thus explain'd by *PLATO* in his *Timæus*: Forasmuch, saith he, as there is no *Vacuum* any where, into which any thing that is moved can enter; and yet our breath continually goes out from us, it is apparent to every one that it goes not into an empty space, but drives the *Air* next to it, out of its place, which again drives away the next to it; and according to this necessity whatsoever is driven into the place, whence the breath came forth, doth follow it. And all this is perform'd at once by a certain *Revolution*, since there is no *vacuity* any where. Wherefore as soon as the *Breast* and *Lungs* have let out the *Breath*, they are immediately fill'd again with the *Air* that surrounds and penetrates the *Pores* of the *Body*. And again the *Air* flying out of the *Body*, and the let out breath, forceth us to draw in our breath again, by the *Passages* of our *Mouth* and *Nostrils*.

XV. One *Motion* is not contrary to another *Motion*, because when two *Bodies* of the same *Bigness* and swiftness meet, they do not lose their *Motion*, but are only reflected, and then so continue their *Motions* again. But *Rest* alone is contrary to *Motion*: And tho' a *slow Motion* may be said to be opposit to a *swift*, that is only because a *slow Motion* partakes of *Rest*.

XVI. For *Rest* is a Continuance of a thing in the same place, or an adhesion to the same *Contiguous Bodies*. This is an *Affection* proper to matter, which consider'd simply in it self, without any force from without impress'd upon it, continues unmov'd, that is, hath its parts continuous to it self. Now this *Rest* or *Quiet* is something *Positive* as well as *Motion*: For *Rest*, according to its *Magnitude*, resists *motion* more or less, alters the determination of *motion*, and keeps the parts of continuous and hard *Bodies* close together, which could not be done by that which is merely *Private*. And indeed forasmuch as *Rest* is something stable and permanent, if compared with *motion*, which is flowing and passing, we cannot deny it *Reality*.

XVII. *Rest* therefore is oppos'd to *motion*, not *Privatively*, as *Habit* and *Privation*; but *Positively*, as two contraries, whereof the one is contrary to the other; for *Rest* is adverse to *motion* by resisting it, and that either by diminishing it, or reflecting it.

XVIII. *Motion* is not a *Real Quality*, as the *Peripateticks* suppose, but only a *Mode* which is not distinct from the *Body*. For we cannot conceive it to be any thing else, but the *change*, whereby a *Body* is translated, or withdraws from some other *Bodies* that immediately touch it. As when standing on the *Bank* of a *River*, we see a *Fish* for some time continuing over against the same place,

without being carried away by the course of the *Water*, which on all sides surrounds it; we must conclude it to be really moved, because the whole outside of the *Fish*, is successively apply'd to diverse parts of the *Water* that do immediately touch it; and because we find all that in it which happens to another *Fish* that swims in a *Pond*; and moreover the effort he useth makes him successively to correspond to different parts of the *Water*. And on the contrary when we see a *Stick* driving in the *Water*, so as to be always apply'd to the same parts of the *Water*, we must say that it doth not move, but lye still, forasmuch as the said *Stick* is without any *Action* of its own, and doth not correspond successively to divers Parts of the *Water*, because a *Stick* in this case, and the *Water*, make up but one thing, which is really moved.

As we cannot conceive an Application to be made to different Parts, without conceiving a *Body* that applies it self to them; therefore we are to judge, that *Motion* is not an *Absolute Entity*, as hath been said before, but only the *Modification* of a *Body* that is moved; and so *Rest* likewise the *Mode* of a *Body* resting. Whence it appears, that *Motion* and *Quiet* superadd nothing more to a *Body* moved or *Resting*, than *Figure* superadds to a *Body* figured. And seeing that a *Body* may either be moved, or not moved, we must conclude, that *Motion* and *Rest* are *Accidental* to *Matter*.

We may also infer from what hath been said, that there is no violent *Motion* in *Nature*, since it is as connatural to *Bodies* to push forwards one another, as to rest and lye still. For *Matter* consider'd in it self, being idle and unactive, and receiving its motion from an *External Principle*, it follows that *Motion* equally agrees to all *Bodies*. Neither can the *Motion* of a *Stone* cast upwards, be said to be violent, any more than the *Motion* of a *Ball* when it falls down perpendicularly to the *Earth*: For as the *Motion* of a *Stone* cast up into the *Air*, proceeds from the force of him that casts it up; so the descent of a *Ball* proceeds from the subtil matter which carrieth the *Earth* and compresseth all its parts towards the *Center*. For the word *Violent* hath reference only to our *Will*, which is said to be forced when any thing happens to it, which it resists and strives against.

CHAP. XV.

Of the Principle of Local Motion.

Forasmuch as *Matter* hath no power to attribute any *motion* to it self, or to remove another *Body* out of its place (as shall be said in the following Chapter) we are to enquire here what is the *Cause* of *motion* in the *Universe*. In which enquiry, that we may follow the order we see in the *World*, we shall pitch upon two *Principles* of *motion*; the one *General*, on which all *motions* in the world do depend; and the other *Particular* or *secundary*, to which all singular *motions* are attributed.

The *First* and *Universal Cause* is that which first put *matter* into *Motion*, and is no other but *God* alone, who bestowed *Motion* upon the *matter* he had created, and preserves the same by the same *Action* by which he produc'd it at first; and because it is agreeable to *Right Reason*, and the *Idea* we have

XIX. *Motion* and *Rest* are the *Modifications* of a *Body*.

XX. There is no violent *Motion* in *Nature*.

I. There are two *Principles* of *Motion*.

God is the first Cause of *Motion*.

of God, that he should conserve his *Creatures* in the most simple way; it seems more than probable that God continues the same *Agitation* in the *Universe*, which he imprest on it at first, yet so as that he can always whensoever it pleaseth him change these *Laws*, which he hath established.

III. The Second or Particular Cause is the meeting of *Bodies*, by which means it happens, that this *Divine Action*, which preserves *Motion*, exerts it self sometimes in these, sometimes in other *Bodies*: Whence the difficulty which ariseth from the Communication of *Motion* may be easily solved; for tho' *Motion*, as being only the *Mode* of a *Body*, cannot remove from one *Subject* to another, which *Regius* unwarily asserts; yet the agitating force, being no *Mode* of a *Body*, may by removing shew it self sometimes in this, sometimes in the other *Body*.

IV. Whensoever therefore *DES CARTES* speaks of the Communication of *Motion*, he is to be understood of that *Power*, which preserves *Natural Things* in the same condition wherein they were constituted at first, and all effects order'd according to the *Laws* appointed for them, and suiting to their *Natures*.

V. There are three *Laws* of *Nature*, which are founded in that most simple Concurrence, whereby God preserves all *Bodies*, which are very conducive to understand the *Nature* of *Motion*.

VI. The First is this: Every *Natural thing*, if it be simple and undivided, always inclines to continue in the same state wherein it is: So that no change can happen to it, but from some outward Principles. Thus a *Round Body*, always keeps its *Round Figure*, neither is the same destroy'd, but by some supervening foreign Agent. And supposing the same *Body* to be moved, it will still proceed further, except it meet with some impediment that puts a stop to its *Motion*. And according to this Rule, we say, that a *Body* once put into *Motion*, for example, a *Ball* struck by a *Racket*, doth not stop at the *Wall* from whence it is reflected; for should we suppose any interruption in its *Motion*, we should be at a loss to find the cause that excites a new *Motion* in it again. Wherefore we must conclude that that which is moved, is always moved, and that which rests, rests always. And for this cause it is that a *Stone* continues its *Motion*, after it is let go out of the hand of him that throws it.

VII. This Rule may easily be gather'd from what we shall say in the following Chapter: For seeing that a *Body* cannot move it self, it follows, that that which rests, must persevere so, except by some outward force it be driven out of its place. And in like manner, when a *Body* is once put into *Motion*, no reason can be assign'd why it should not continually proceed therein, with the same *swiftness*, as long as it meets with nothing that stops its career. For since nothing can be done without a Cause, the state of a *Body* cannot be changed without the Action of a Cause. Hence it is that a *Lead* Bullet being let fall from the top of a *Mast*, notwithstanding the swift course of the *Ship*, yet falls down straight to the bottom; for the *Motion* of the *Bullet* being a Compound of *progressive* and *descensory Motion*, and both of them continuing in the same state, it is evident that the *Bullet* can fall no otherwise than it doth.

Wherefore we shall meet with no change in *Bodies*, as to *Motion* or *Rest*, *Swiftness* or *Slowness*, *Figure*, *Situation*, *Magnitude*, &c. which do not proceed from without, the searching out of which Causes is the particular task of *Natural Philosophy*. *Water* indeed doth by degrees lose its *Heat*, but then it is no simple, and undivided *Body*; for it derives its agitation from without, and retains it as long as the agitating Cause continues; but forasmuch as the Cause ceaseth, and the more thin parts of the *Water* Evaporate, and communicate their *Motion* to the Neighbouring *Bodies*, by this means the *Water* becomes reduc'd to its former state of Coldness.

You'll say, a *Stone* cast up into the *Air*, doth after a short time fall down again to the ground, which would not be, if a *Body* once moved, were inclin'd to continue its *Motion*; for according to this Rule, it ought continually to proceed, tending upwards.

I answer, that a *Stone* falls down to the ground, not because it willingly desists from its *Motion*, but because it is hindered by the *Bodies* it meets with on its way from proceeding any further. For the *Air* and fluid Matter that is in it, do not without difficulty admit the entering of other *Bodies*; yea and besides do very much resist them, as is obvious to our sense of Feeling. For the subtil Matter, which thrusts *Bodies* downward, hinders the *Stone* from being carried up to Heaven. So that we our selves, when we leap up from the *Earth*, should still continue in the same *Motion* mounting upwards, if the subtil Matter which surrounds the whole *Earth*, did not drive us downwards.

What hath been said of a *Stone* falling to the Ground must likewise be understood in General of all other *Bodies*: Wherefore if we see a *Body* in its *Motion* describing the four sides of a *Square Figure*, we must conclude that at every one of the said Angles where it changeth its determination, it hath been forc'd to it by the meeting of some other *Bodies*, which have oppos'd its *Motion* and determination. And forasmuch as a *Circle* is Equivalent to a *Figure* of an infinite number of sides, it follows, that a *Body* which is circularly moved, must suffer a continual violence by meeting with several other *Bodies*, for without this it could never move in a round Line.

But the chief reason that moves us to assert, that a *Stone*, or any other *Body* would persevere in its *Motion*, if we were not hindered by other *Bodies*, is, because *Rest* is contrary to *Motion*, and nothing by its natural Propensity tends to its contrary, that is, to its own Destruction; and consequently a *Body* if once moved will move always, or if at rest, will always continue so. And in this Principle alone we place the Power of the Action and Resistance of *Bodies*. For as a thing that is united, hath a Power to resist its being separated from that which rests, to oppose that which would put it into *Motion*; so that which is moved hath a Power to continue in its *Motion* with the same *Swiftness*, and towards the same place.

Thus a weight hanging at the end of the *Pack-thread* A B which by outward force is mov'd this way and that way, if it were transmitted to G, would fall down thence, and mount up to D, and always retain this Equality of *Motion*; neither would it ever, by slackning of its *Motion*, come down

VIII. Every change proceeds from outward Causes.

IX. Why a Stone after some time, falls down again to the ground.

X. Answer.

XI. No body moves circularly but by the intervening of outward force.

XII. Another reason why Bodies persevere in their motion.

XIII. Why a Body ceaseth to move.

Figure 5.

down to E and F, but that the *Air* hinders it from continuing its begun Motion from G to D. Forasmuch as no reason can be assign'd, why that which is, should cease to be, except a more powerful thing do hinder and oppose its force.

XIV. The Second Law of Nature is this: Every Body in Motion, of it self tends to prosecute its Motion according to a right line, and not according to a crooked line. Notwithstanding that, many Bodies are forc'd to turn aside by their meeting or jutting against other Bodies, and that, as hath been said before, the whole circle of Bodies moves together in every Motion. This Rule is infer'd from the Definition of Motion, because it affirms nothing concerning Motion, save only that it is a Translation of one Part of Matter, out of the Neighbourhood of those Bodies that do immediately touch it, &c. into the Neighbourhood of other Bodies. So that except this Translation be most simple, that is, by right lines, and not crooked, we have attributed something to Motion, which is not contained in the Essential Notion or Definition of it, and so consequently that which doth not belong to its Nature. For whatsoever is moved, in every moment of its Motion, is determin'd to continue its Motion to some part or other, in a Right Line. Forasmuch therefore as God preserves Motion in the most simple manner that may be, and every natural thing continues in the state wherein it is, the Body moved will always continue its Motion in a Right Line, except it be hindered from without.

XV. If you demand why every Motion tends to a Right Line, and not to a crooked? I answer, because all the least parts that are found in a Crooked Line, are right Lines; and since the circulating Body ultimately exists in one of them, it follows according to the former Rule, that as soon as it is restor'd to its Liberty, it perseveres in the same state, and continues its Motion in that Right Line which there toucheth the Circle. But if the least parts in the Circle were crooked, the moved Body being continually carried along them, and afterwards left to its Liberty, according to the foregoing Rule, would pursue a crooked Motion, conform to the crooked particle of the Circle where it was last: But since this doth not happen, it is manifest that every Circle in Nature is a Polygon, or a Body of many Angles.

XVI. This Rule of Nature, as well as the foregoing, may be demonstrated from the consideration of the Divine Perfection, that is, from the immutability and simplicity of that operation whereby God conserves Motion in the Universe. For as God preserves Motion in any Body, by making that Motion which now is, to continue to exist, without any regard had to the state wherein the Body was before; so he likewise continues to direct the Body moved to that Term, to which it is directed, at the present instant of time. But there is never any instant of time wherein it is not disposed to continue its Motion in a Right-Line, tho' before it was carried in a crooked line, and accordingly will pursue its motion in a Right-Line. This is clearly made out by DES CARTES in the 2d part of his Principles, Artic. 39. by the example of a Stone A, whirl'd about in a Sling AE, which tho' it be turn'd round in the Circle LABF, yet withal hath a tendency towards the Tangent Line ACG. For tho' the Stone first proceeds from L to A by a crooked line, yet nothing at all of that

Obliquity can be understood to abide in it, whilst it is in the Point A. Because tho' the Stone be moved round, yet forasmuch as in every moment of time, parts may be assign'd that have no crookedness at all, it cannot be suppos'd to retain any obliquity, when the detaining force ceaseth.

Hence it follows, that no Body of it self is moved in a Circular Motion, forasmuch as that always proceeds from an outward cause, which hinders the Body moved to pursue its Motion in a Right Line. Upon this account it is also that Wooden Bowls dashing against one another, are often whirl'd round; and so Water likewise, when it is hastily poured into any Vessel: Yea, in every motion there is a circulation of Bodies, as shall be shewed hereafter.

Another Consequence is, that all Bodies circularly moved, do either actually recede, if they be not hinder'd; or endeavour to recede, if they be, from the Center of their Motion: Because, as soon as the detaining force ceaseth, they begin to move in a Right Line. This is the reason why the Water doth not fall down out of a Bucket of Water as long as it is whirl'd round; and that it strives to recede from the Center, we may gather from hence, because upon making a Hole in it, the Water runs out immediately. This Rule is of very great use for explaining of the Heavenly Phenomena. Now this strife of receding from the Center, is either greater or lesser, proportionable to the Agitation, as any one may plainly perceive in the whirling about of a Sling.

Forasmuch therefore as all Bodies moved round, strive to continue their Motion in Right Lines; it follows, that when many Bodies are so moved, every one of them must strive to move by the Tangent ACG of the Circle which it describes; and really move by the same Line, as soon as the causes that have hinder'd it be taken away. It is visible also that the most strongly moved Bodies, must at the same time describe longer Tangents than those that are more weakly moved, and consequently more withdraw themselves from the Center of their Motion, and by the same means force the weaker Bodies to approach to the Center.

Another Rule is; Whensoever the Moved Body, meets with another Body in Motion, if it have not as great a force to pursue its course by a Right Line, as there is in the other Body to hinder it, then it is turn'd out of its way, but yet continuing its Motion, loseth only the Determination of it. As it is evident in hard Bodies, which when they dash against another Body, do not therefore cease to move, but are reflected to the opposite part. But if one of them have a greater force than the other, then it pusheth it along, and as much of its own force as it imparts to this other Body, so much it loseth; as when a hard Body meeting with a soft, by communicating its own Motion unto it, ceaseth to move and lies still. Wherefore we are not to suppose that when a Ball is thrown into a Heap of Sand, that its Motion is lost; but that it is communicated first to the Particles of Sand, next to the Air, and other neighbouring Bodies, notwithstanding the said communication be not visible to our Eyes.

XVII. The Circular Motion of a Body proceeds from a Cause External.

XVIII. Every Body that's whirl'd round, endeavours to recede from its Center.

XIX. And that which is strongest doth the more recede from the Center.

XX. The Third Law of Nature.

XXI.
The Reason of the
Third Rule.

The Reason of this Rule is to be fetch'd from the First; for seeing every thing inclines to continue in the state wherein it is, it will follow that that which is weakest must be changed by the stronger, as experience teacheth.

XXII.
From this Law arise
those changes which
happen to Bodies upon
their meeting one
another.

From this Third Law ariseth almost all the changes we find in Bodies, caused by the various resistance and occurrence of other Bodies; the effect of which occurrence will be different. First, according to the magnitude of those Bodies. Secondly, according to their Superficies, whereby they press upon each other. Thirdly, according to the swiftness and force of their Motion. Fourthly, according to the Rest and contact of Parts in that Body against which another dasheth, as shall be more amply shewed Part V.

XXIII.
How to
measure the
Quantity of
motion.

The Quantity of Motion in a Body is known partly by the length of the Line which the Body moved runs through; partly from the quantity of its Bulk, which is transfer'd together with it. Thus a Square Body of one Foot, being moved the length of 10 Ells, is said to have a certain Quantity of Motion, which would be double, if an equal way, were added to the former length, which that Body shall run through. Again, if a Square Body of one Foot, should run through the space of 10 Ells, there would be a double portion of Motion in it, with respect to a Square Body of half a Foot. Whence it follows, that Bodies of different magnitudes, may have the same quantity of motion. Thus the Square Body of one Foot, and that of half a Foot would have the same quantity of motion, supposing the former to run through a Line of five Feet, and the other a Line of ten Feet.

XXIV.
Unequal
Bodies may
have an
Equal
quantity of
motion.

From hence it is evident, that to the end two Bodies of different magnitude may have an equal quantity of motion; it is necessary that the Lines they run through, be reciprocally taken according to their bigness. As supposing one Body to be thrice as big, as another, it is necessary that the Line it describes by its motion, be only the third part of the Line, the lesser Body runs through. And upon this ground we may build these four following Maxims.

XXV.
The First
Maxim.

Two equal Bodies, have equal Quantities of motion, when in equal time, they describe equal Lines.

XXVI.
Second
Maxim.

Two equal Bodies have unequal quantities of motion, when in equal time, they describe unequal Lines.

XXVII.
The Third
Maxim.

Two unequal Bodies have equal quantity of motion, when in an equal space of time, they describe Lines, which are of a reciprocal Proportion to their magnitude.

XXVIII.
The Fourth
Maxim.

Two unequal Bodies have unequal Quantity of motion, when in equal time they describe Lines which are not reciprocal to their Bulk.

CHAP. XVI.

A Body can neither move it self, nor another Body.

I.
Motion is
something
distinct
from the
force that
moves.

TO know whether the Body moved hath its motion from it self, or whether it receives it from some outward Cause, we are to suppose two things in motion; the one residing in the thing moved; and the other in the mover. The former of these is the successive application of the Body moved, to the different parts of the Body that doth immediately touch it; and the second is,

the force that causeth this application. Motion in the thing moved is nothing else but a mode, as hath been said in the foregoing Chapter; and consequently cannot pass from this Body into another, because every mode is inseparably tyed to its Subject. But motion consider'd with spect to the mover, is not a mode of the Body moved, because we find by experience that it passeth from that Body into another; so that motion in the first Sense, is only modally distinct from the Body, whereas the efficient mover is Really distinct from it.

It is evident therefore that a Body hath not its motion from it self, in the first of these Senses, because this motion consists in an Application which is Accidental to the Body; and that every change which happens to any Subject, proceeds from an External Cause. Neither can it give it self the Efficient motion; because this motion likewise is Accidental to the Body: Wherefore it follows that the Body must receive its motion from something that is without it.

Moreover, a Body cannot be said to have that of it self which it may lose, without ceasing to be what it is; now it is evident that every Body can wholly lose its Motion, without ceasing to be a Body: Wherefore we must conclude that no Body has any motion of it self.

If a Body of it self had the Power to move it self, this Power would be Essential to it, and consequently the Body would move always, and with the same force, which is contrary to experience, which teaches us that a Body sometimes moves more, and sometimes less, and sometimes not at all: Wherefore it receives its force to move from something without it. Now there is nothing without or external to matter but Spirit; it is Spirit therefore that moves the Body, that is to say, God, who makes the parts of matter apply themselves successively, as to their outides, to other parts that immediately touch them. Wherefore, since God cannot produce motion without acting, nor act otherwise than by his Will; we must own that the moving Power is nothing else, but the Will God hath to move the matter. Whence it follows also, that as the Will of God is unchangeable, the quantity also of the moving force must always continue the same, and that if it change by encreasing or diminishing, this is not with respect to its Principle, but with respect to the different Bodies on which God exerts that Power, as we have already shewed.

From whence we gather this Conclusion also, that no Body can move another. For how shall it move another Body, seeing it cannot move it self?

If you say that the Power of moving is not distinct from the thing moved, and that therefore it is not repugnant for a Body to apply it self to divers places: If it were so, it would follow that the force whereby God produceth motion in the Universe, must include the notion of Extension; and seeing the same is not distinct from God, it would follow, that God is Corporeal.

Wherefore, ARISTOTLE 8 Physic. Chap. 4. tells us, that no Body can be moved by it self, and consequently that Heavy and Light Things are not moved of themselves, but by others. For if they could move of themselves, they might also stand still of themselves; for whatsoever is a cause of walking to it self, is also the cause of not walking; wherefore if Fire of it self did move upwards,

II.
Every Body
is moved by
another.

III.
A Body
may not be
moved at
all.

IV.
If a Body
were mov'd
of it self,
it would be
in perpetual
motion.

VI.
The Power
of moving
differs from
the thing
moved.

VII.
Aristotle
teacheth
that no Body
can be
moved by it
self.

it would also be able by its own strength to move downwards. For it is not, saith he, agreeable to Reason, that those things should only be moved one way, that do move themselves. Moreover, how can it be that a continuous thing should move it self? For as far as anything is one and continuous, it is not capable of Passion: But as soon as it is separated, then one can act and the other suffer. Nothing therefore moves it self, because everything is one and connext; nor another, that is one continuous thing with it, but in every thing it is necessary that that which moves, should be divided from that which is moved.

VIII. And tho' ARISTOTLE in the place before quoted, seems to own a Principle of Motion in Inanimate Bodies, this is only to be understood of a Dispositive, and not of an Active Principle; after the same manner as a Knife, Sword, Leaver, or any other Engines, are fit or disposed to act something, and do moreover act and move, when they are employ'd by an External Agent, but never can set upon a work of themselves.

IX. To make this the more evident, let us suppose that all the parts of matter from the Beginning were destitute of all motion, and to have lain mingled together, having Extension only. Which of all these think you, would have begun to move first? Or what force could they have had to move either themselves or others that touch'd them? Seeing therefore we can conceive nothing there, besides Extension, and that Motion is not an effect of Extension, we must say, that none of them could have the Power either of moving themselves or other Bodies. And what we conclude of the several parts of the matter contained in the Chaos, the same we must conclude of the whole: For whether could that vast Body move, seeing that it is indefinitely extended, and we can conceive no Bounds or Limits in it?

X. We must conclude therefore, that no Body can move it self, since the force of moving is distinct from it; nor another Body, since a Body that moves another must lose as much of its own motion, as it imparts to the other Body: But how shall it impart that which it hath not? Wherefore God must be concluded to be the Author and Principle of all motion in the World.

XI. If you object, that Animals do move themselves, without requiring an External Cause by which they might be moved. I answer, that the motion of Animals depends on that of the Animal Spirits, which being of a fiery nature, and carried through the Body like a Flame or Wind, do easily move the Members of it. For in the Animal Spirits, besides the thinnest and most moveable Particles of the Blood, is also contained much of the Celestial matter, which because of the extream subtilty of its Parts, is perpetually and necessarily agitated. Forasmuch therefore as these Spirits being either simply moved or determin'd, or besides also altered, do easily diffuse themselves into the Nerves, which are extended from the first Original of Sense and Motion to the Muscles and parts to be moved, it is not difficult to conceive how the Figure of the Muscles being changed by the Influx of Spirits, by their contraction or extension, do contract or extend the parts to which they are joyned, and consequently can be moved with innumerable different

CHAP. XVII.

Concerning those Motions which commonly are ascrib'd to Nature's avoiding of a Vacuum.

SOME are so liberal as to allow Knowledge indifferently to all things, and suppose Inanimate Things to be indued with a kind of Intuitive Perception. For if you demand of them why a Stone tends downwards, why Water gathers up it self into round drops, why Plants delight in such and such ground; they have a cause ready at hand, viz. That a Stone tends to the Center of the Earth to rest there; that Water affects a Round Figure, to preserve it self from its Enemy; and that Plants delight in such a Soil, because they know their convenient Aliment; and that Water mounts up on high, to avoid a Vacuum, and to preserve the Union that is between Bodies. Yea, we shall hear some boldly asserting, that the Earth for no other Reason, took to it self a Spherical Figure, than that it might be able, to resist the impulses, of the Heavenly Bodies; and that as with an Army in Battell-array, it might be in a better condition to oppose its Adversaries which on all sides press in upon it.

Thus they tell us, that the Water mounts upwards in Hero's Fountain, because Nature abhors a Vacuum. Which way of speaking hath always appear'd very strange to me, and much like that, as when a Man being demanded why Coals are brought to London from the North parts of England, should answer, for fear of Cold: For these answers do not in the least satisfy the Question, which is not concerning the Final, but the Efficient Cause. Neither indeed can the Avoiding of a Vacuum be said to be the Final cause of the Waters Ascent; First, because the Fear of a Vacuum is vain; neither can Nature abhor that which cannot be; and consequently a vain cause is ascrib'd to those Natural Effects, which are suppos'd to proceed from this fear. Secondly, forasmuch as this Fear is perpetual, and that there is a continual necessity that all Bodies be united together, therefore the Water ought to ascend perpetually, which is contrary to experience; for we find that in Spouts and Pumps the Water ascends only to a certain degree, viz. to thirty one Foot and an half, where it stops, and can rise no higher.

Now the Reason why Water can only be raised to a certain height, is this, because the weight of the pressing Air, is then, as it were of an equal poise with the weight of the Water that is driven upwards; so as that the force of resisting in the Water, becomes equal to the pressing force that is in the Air. Thus by Example, from the waters mounting continually in Pumps to the height of about 31 Foot and an half, above the Surface of the Water in which the end of the Pump is dipt, they conclude that a Column of Water of that height weighs as much as a Column of Air of the same bigness, how high soever it may mount.

Now to the end that the Cause of these motions may be the better understood, we'll take for granted what hath already been proved, that no Body moves it self, but must be moved by another Body, that immediately toucheth it, pushing against it: And forasmuch as in all the Instances we shall here alledg, nothing is found besides the Air, that toucheth

Tis absurd to attribute knowledge to Bodily things.

II. The improper Answer of some Men.

III. Why Water can only rise to a certain measure.

IV. No Body is moved but by that which immediately toucheth it.

toucheth the *Bodies* moved, we must conclude that they are pushed on by the *Air*. Moreover considering that the *Air* always retains a great Quantity of watry Particles, which tho' dispersed in divers places, do notwithstanding retain their own *Heaviness*, we cannot doubt that the *Air* is *Heavy*, and that by its weight it presseth the *Bodies* it lies upon. As may be seen in a *Syringe*, out of which if we draw the *Sucker* a little way, it of itself runs to the bottom again, because the *Air* that is above it, and immediately toucheth it, by its weight presseth it down to the bottom.

V. Moreover, we are to suppose, that seeing there is no Vacuum in Nature, when one *Body* is moved, the same must come into the place of other *Bodies*, and that which is driven out, must at the same instant take up the place of another *Body*, and so consecutively one after another, till the last *Body* enters into the place which was left by the first; so that all *Motions* in the *World* are in some sort Circular.

VI. How those *Motions* are performed which are commonly ascribed to the fear of a Vacuum. These things so far understood, it will be easy to apprehend, that all *Motions* which are ascribed to the fear of a Vacuum, are produced, for that some *Body* being pushed out of its place, does as much for the *Body* that is next to it, and so on, till the last *Body* enters into the place left by the first *Body*.

VII. How the *Water* comes to ascend by a crooked Pipe. This motion is evident in a Bent or crooked Pipe, the shorter leg whereof BAD being put into the Vessel E, fill'd with *Water* (for it is supposed that the *Liquor* which is in the part of the Pipe FD, as standing in a liquor of equal *Heaviness*, is not at all pressed by it, and therefore has no gravitation at all) and the longer Arm BC being extended towards the *Earth*; The *Water* that is inclos'd in the longer Arm, being heavier because of its greater Quantity, than that which is in the short Arm BAD, it must needs by reason of its Weight fall out of the Pipe BC into the *Air*, and by driving that out of its place, presseth the surface of the *Water* D, and makes the *Water* to ascend by the short Arm DAB, from whence it is carried to that place, which the *Water* falling down out of the Arm BC, hath forsaken. For seeing that the surrounding *Bodies*, have no place whither to withdraw themselves, they hinder the *Water* and *Air* from entering. But in the longer Arm BC whence the *Water* falls down, room is made, which the *Water* thrust down by the pressing *Air*, may take up at the same instant.

Figure 7. VIII. And the *Water* runs in this crooked Pipe, as long as the shorter Arm BAD, is depressed, or not of an equal height above the surface of the *Water* with the other Arm BC. But when both the Arms are of an even height, the outflowing of the *Water* will cease, for being equal, the one cannot prevail over the other. And if then the same ascent and descent of the *Water* should continue, it would follow that there must be a greater quantity of *Water* in the Arm BC, than in the Arm BAF, which is contrary to our supposition.

IX. Why the flux of the water is by little and little diminished. This shews clearly why the flux of the liquor from these Pipes is swiftest at the first, and afterwards decreaseth by degrees, because the Arm from whence the *Water* runs out, is at first higher than the other, which height being continually lessened by the efflux of the *Water*, the swiftness of the

motion of the liquor must be proportionably diminished. And when both the Arms are of an equal height, the efflux must cease, and the *Water* be at a stand in them both.

X. Wherefore no wonder that they lost their labour who endeavoured by the weight of the *Water* in a crooked Tube ABC to find out a Perpetual Motion. For observing that much *Water* was contained in the wider Arm A, and that the longer Arm C contained only a little *Water*, they hoped that the *Water* enclosed in the Arm A, because of its quantity and weight, falling down through the hole F, would have sufficient force to press the *Air* G, and by means thereof also pressing the surface of the *Water* D, contain'd in the Tube E, might drive the *Water* through the longer Arm C, into the Arm A, and from thence falling down again through the Hole F, of the wider Tube, into the Tube E, might produce a perpetual motion of the ascending and descending *Water*.

But this was but a vain attempt of theirs; for tho' all the liquor contain'd in the wider Arm A, be much more heavy than what is in the longer Arm C, yet because the *Water* that is contain'd in the Globe A, doth not with its whole *Body* press the subjacent *Air*, but only with that part of it which perpendicularly answers to the Hole F, it cannot remove the *Air* that is under it out of its place, and consequently neither can it repel the *Water* contain'd in the Arm CB, into the other Arm BA, because the *Water* in CB exceeds that in weight which in the Arm A perpendicularly answers to the Hole F. And the reason why the whole liquor which is contained in the Arm A, cannot press all the subjacent *Air*, is, because the other parts of the *Water* contain'd in the longer Arm, falling down perpendicularly, tend directly to the parts of the Arm HI, diametrically under them, and therefore no wonder if they cannot press the subjacent *Air*; otherwise the *Water* FB, which is the lighter, would by its pressure raise up the heavier DCB, which no Naturalist can admit.

XI. The same cause that makes the *Water* ascend by the fore-said crooked Tube, raiseth it likewise by a long shred of Cloth or Linnen. For first of all the piece of Cloth must be well dipt in the *Water*; because as long as that part which hangs down without the Vessel is dry, no filtration will follow: Now the outward parts of *Water*, wherewith the Cloth is made wet, do so insinuate themselves between the Threads of it, as to make a kind of Tube or Pipe (but into which no *Air* can enter) and in the mean time the consequent parts of the *Water*, which are contained in the said Pipe, flow towards that part of the Cloth, which hangs lower down on the outside of the Vessel, in like manner as it happens in the crooked Tube or Pipe.

XII. Thus likewise we see how a Bellows by being distended, becomes filled with *Air*; for seeing all places are full, and no Vacuum is found in the Universe, by distending the Bellows, the *Air* is driven out of its place, and finding no other passage, is forced to enter by the Nuzzle of the Bellows.

XIII. Respiration also is performed in us much after the same manner: For the *Air* entering into our Bodies, dilates the same by means of the Muscles of the Breast and Stomack; whereupon the neighbouring *Air* because of its fluidity is easily turn'd out

X. The Motion of *Water* through a Pipe cannot be perpetual.

Figure 8.

XI. The Reason of the former assertion.

XII. How water is drawn out of a vessel by a Filter.

XIII. How the Air is drawn into a pair of Bellows.

XIV. How the Air in Breathing enters into our Breast.

out of its place, and consequently drives before it that also which is next to it, and thus the Air being pushed by the Breast, and other subsequent Air, is thrust down through the Wind-Pipe into the Lungs and Breast, and from thence also does return the same way. For Respiration is nothing else but an Alternate expansion and contraction of the Breast, by which the Air is thus driven to and from the Lungs.

XV.
Respiration
cannot be
performed
by At-
traction.

By this experiment we may solve all, or most at least of those Phenomena, which Philosophers have attributed to Attraction. For it cannot be understood how in Respiration the Air is sucked in, or by what means the Lips, Lungs or any other part of the Body can hook in the little Particles of the Air and attract them: But when the inward parts are dilated, we easily apprehend that at the same time they push away the neighbouring Air, which partly by this pressure, and partly by the Elastic virtue caused by the Agitation of its Particles, is driven into the Breast, and afterwards expelled again, viz. when the Lungs subside again and are contracted.

XVI.
How the
Flesh of
mans Body
comes to
rise up into
the Cup-
ping glass.

We must not omit here the Experiment of Cupping Glasses, by means whereof the Flesh is raised in order to Scarification, and by force driven into them. For the Air being in a manner wholly expelled out of the Cupping Glasses, by the intromission of Fire, it must thereupon be condensed, and its parts more closely prest together, than is consistent with its temperament: And therefore whilst the Subtil Ether crouds in betwixt its Particles, this External Air strives to dilate it self again, and to return to its natural state: And in this strife it presseth all the Bodies that do surround it, which as long as they strive against this force, no Bodies are turn'd out of their Places. But when the Air in the Cupping Glasses begins to grow cold, it hath no power any longer to resist the pressure of the Air striving to dilate it self, and therefore suffers the outward Air, by pressing the Flesh to thrust it into the Cupping Glasses, and to drive out the subtil matter which was contained in them through the Pores of the Glass.

XVII.
Much in
the same
manner as
the water
mounts up-
wards.

Almost in the same manner as we see the Hand in a Pneumatick Engine (after that the Air is exhausted out of the Recipient or Glass Vessel) to swell and spread. And for the same reason, a Viol with a narrow Mouth, if the Air by sucking be drawn out of it, and afterwards you stop the Hole of it with your Finger, and so dip it into the Water, it will become fill'd with it; because the Ambient Air by its weight pressing the Surface of the Water, drives it into the Viol, in which the Air that remains, being rarefied, for the want of the Air that is extracted, retains only a weak Elastic force, and so cannot oppose the pressure of the outward Air.

XVIII.
How In-
fants suck
Milk out of
their Mo-
thers
Breasts.

Hence, it also appears how improperly Infants are said to suck Milk out of their Mothers Breasts. For if we consider how a Child draws Milk, we shall find that he doth not attract it by Sucking, but that it is driven into his Mouth: For the Child when it is about to Suck, doth dilate his Cheeks, and lay hold of the Nipple, wherefore the Air, that is next to his Cheeks, must be driven out of its place, which pressing the Breast of the Mother or Nurse, drives the Milk into the Childs Mouth. And accordingly also Nurses use to press their

Breasts, to facilitate the Expulsion of the Milk. And the same doth yet more clearly appear in Brute Animals; for Lambs use to thrust their Heads against their Dams Dugs, thereby to squeeze out the Milk into their Mouths.

CH A P. XVIII.

Of the Determination of Motion both Simple and Compound.

HAVING explain'd the Nature of motion, and determined the Causes of it, it remains now that we discover its Properties, and the Accidents that accompany it. The inseparable Properties of motion are Determination, Swiftnes, and Quantity. For every Body that is moved, moves some way or other, runs through a certain Space in a certain time, and that Space may be divided into certain degrees. Inasmuch that the respect which Bodies moved have to the Coast towards which they are moved, is called Determination; the respect which they have to the Space they run through in a certain time, is called Swiftnes, and this Swiftnes distinguished into degrees, that is, into equal Parts, is called the Quantity of motion.

I.
What the
swiftness,
Determina-
tion and
Quantity of
motion is.

The Determination of motion is that whereby the Body moved, is directed from the Term a quo, to a certain Term: Such as is that disposition in a Stone, whereby it tends rather to the Center of the Earth, than towards any other part whatsoever. We shall the better understand its Nature by dividing motion into Straight, Circular and Mixt. Straight motion is a Translation by the shortest way that can be, viz. by a Right Line. Circular motion is a Translation about a Center and Axis. And mixt motion is that which is compounded of a Circular and Straight Motion, or of two straight ones, or innumerable other various motions. As the motion of a Knot in a Wheel about the Axle-tree, which is circular, and also straight with respect to the way along which it goeth.

II.
What the
Determina-
tion of Mo-
tion is.

And that a mixt motion may be compounded of two right motions, is evident, when in the square Figure ABCD, the uppermost side AB, is moved with a straight motion towards the opposite side CD, and that at the same time the point A, of the upper side AB, be moved towards B, the other extremity in a straight motion. For by this means the point A, will not describe a Perpendicular AC, but a Transverse Line AD, yet a straight one, which Geometricians call a Diagonal, when it reacheth the opposite side CD.

III.
How a
mixt moti-
on may be
compounded
of two
straight
motions.

Figure 9.

These things being thus briefly laid down, I say, that motion consider'd in it self differs from Determination towards any Coast; which I thus prove. Whatsoever can be taken away from any thing, without impairing of it, that doth not constitute the nature of that thing. But Determination may be taken away, the motion still continuing whole and entire: Therefore Determination doth not constitute the nature of motion. The Minor is thus proved: Suppose the Body A, to move towards B, and to be hindered by the Body B, from going any further, A according to the Laws of motion, will retain its own motion entire: But when it pursues its motion, it is no more carried the same way it was before, because it is hindered by the Body B: Wherefore its motion abiding entire, and having

IV.
Determina-
tion is a
Mode
distinct
from Mo-
tion.

Figure 10.

having lost its first Determination, it will begin to move the contrary way: And therefore motion is distinct from Determination.

V. The Determination of motion may be changed, without any change of motion.

This may be proved; for that motion, as was said before, is not contrary to motion, neither do they ever destroy one another in the same Subject; whereas one Determination is contrary to another, and the one destroys the other: Wherefore they are different. For proof of the Minor, suppose the Body A, to be bigger than the Body B, and to dash against the Body B, either resting, or more slowly moved, A moving more swiftly, will alter the Determination of B. But if A and B be supposed equal in bigness, and that with a different Determination and equal swiftness they approach to one another, they will fly back from each other the contrary way, with the change of both their Determinations, whilst the same Quantity of Motion still continues in them. Moreover, Motion, and its Determination are two Modes, one whereof may be superadded to the other, in the same Subject; after the same manner as Swiftness and Slowness happens to Running. And therefore as Swiftness may be taken away from the running of a Stag, and is actually taken away, when he runs slowly: So likewise can the Determination of motion be easily changed, the motion it self still continuing.

VI. Motion, and the Direction of it to a certain part, have different Causes.

Figure 11.

This will appear unquestionable, if we consider that the cause of Motion and Determination is not one and the same. For that force whereby the mover strikes a Ball with a Racket from C towards B, is not that, by which it is determin'd to tend this way rather than another way, but wholly diverse from it. The force of the Racket is that which moves the Ball, and could as well move it towards any other parts, as towards B. But the Determination depends on the Situation of the Racket, which so disposeth it, as to make it to be carried to B, and might have dispos'd it after the same manner, tho' it had been struck another way. And therefore the Determination of the motion of Bodies does not so much depend on the force of the mover, as on the Situation of the mover, and circumjacent Bodies. Wherefore it is manifest, that it may happen that the Ball being struck from C towards B, may be turn'd aside by meeting with the Earth EF, viz. by a change of its disposition, by which it tended towards B, the force of its motion all this while continuing the same, there being nothing common between them.

VII. There is no Rest in the Point of Reflexion.

Those who do not distinguish the Determination, from motion it self, nor one Determination from another, do suppose that the Motion of Reflexion is contrary to direct motion; and instead of owning no other contrariety, but what is between motion and rest, they assert, that between reflex motion there is a moment of rest, which is absolutely impossible. For this motion being interrupted, there would be no cause assignable, by which it might be excited anew; but rather having obtained a new way of Existing, according to the Laws of Nature it ought to continue in the same condition, as much as if it had been at rest for many ages together. Neither is there any more necessity why it should begin to move again, than why a Triangular Body, which by motion is become Spherical, should not retain that Figure, as much as if it had receiv'd it from the beginning.

Because every thing, as far as in it lies, continues in the same state wherein it is.

Determination is double, simple or compound. Simple Determination is that, whereby a Body after a simple manner tends to the Term to which it is directed. Such as is the Determination whereby the Body A, from the same point A, by the right line AB, moves towards the Body EF diametrically opposite to it.

VIII. Determination is either Simple or Compound.

But when a Body falls directly and perpendicularly from A to B, on another hard and unmoved Body EF, it is evident that it must fly back by the same line BA, seeing there is no reason why it should tend to one side more than to another. Yea, forasmuch as the Determination of the Body A, is direct from A to B, and is simple, it is necessary according to the Laws of the unchangeableness of Nature, that it always continue in the same state, without altering.

IX. A Body falling perpendicularly upon another Body, must be perpendicularly reflected.

Compound Determination is, when the Body moved is after a compound manner directed to another Body: As when the Body C, from the Point C, by the Transverse Line CB tends to the Body EF obliquely oppos'd to it. For the Mode of this tendency is compounded of a Lateral Progressive motion CG in length, and a descensory CB in height: Because every motion that depends on two or more causes, is compound. Wherefore, a Bullet shot out of a Canon, doth not describe a straight, but a crooked line only, because two divers causes concur to its motion: the one driving out the Bullet, which by degrees grows less, since the Bullet, as it proceeds, communicates its motion to the Air, which it thrusts out of its Place; whereas the other motion, which is descensory, is encreased, daily experience teaching us that Heavy Bodies move more slowly at the beginning of their descent, than in the progress of it.

X. What compound Determination is.

CHAP. XIX.

Concerning Reflexion and Refraction.

From what hath been said, may be easily gather'd what it is for a Body to be Reflected or Refracted. For since in Compound Determination the Body moved, meeting with another Body, tho' it keeps the same motion, yet only retains one part of its Determination; it so happens that because it cannot go forwards, it suffers an Oblique Reflexion towards the opposite part; but if it can, then Refraction. Hence Reflexion may be describ'd, The Regress or Return that happens to a moved Body, because of the meeting of another Body, which it cannot penetrate. And Refraction, is the incurvation, or change of Determination in the Body moved, which happens to it, whilst it enters or penetrates the Medium.

I. What Reflexion and Refraction is.

Thus if a Body moved directly, meets with another that is unmoveable, it must be reflected by the same Line by which it is directly moved, there being no cause to oblige it, to describe any other. For example; if the Body G be mov'd directly by the Line GB, towards the Earth CE, which I suppose unmoveable, it will not be reflected by the Lines BA, or BF, but by the Line BG. The Reason whereof is, because the Determination of the Lines BA and BF is compounded, and that no cause can be assigned, that should oblige the Body G,

II. Sometimes a Body is directly reflected.

Figure 12.

G, which was moved with one only Determination toward the Earth CE, to retire from thence with two Determinations.

III. But if the Body A be mov'd obliquely by the line AB, and that it meet with the Earth CBE, which is suppos'd unmoveable, it will be reflected by the line BF, which is diverse from the line AB. To prove this, draw through the Points A and B, the lines AC and HB, perpendicular to CE. This done, consider in the first place that the Body A, moving towards B, doth at the same time approach to the lines CE and HB, that is to say, that its Determination from A to B, is compounded of its Determination from A to C, and from A to H; or that which is the same thing, of its Determination from above to beneath, and from the left to the right. Consider in the second place, that the Earth CBE opposeth it self to the Determination from A to H, and by consequence that the Body A, when it meets with the Earth, must take a quite contrary Determination to that which it had, by which in an equal space of time, it must advance equal quantities; that is to say, if within a Minute, the Body A, descended by the line AB, to the line CBE, it must in another minute remount again from the line CBE by the line BF.

IV. But that we may know more distinctly to what part the Body or Ball struck, must rebound, let us describe a Circle from the Center B, at the Interval BA. For all the Points which are distant the same Interval from B, as A is, do meet in this Circumference. Now to be able particularly to determine this Point, let us with Des Cartes Chap. 2. Dioptr. erect three perpendicular lines AC, HB and FE, upon CE, so as there may be the same distance between AC and HB, as between HB and FE. Next let us say, that in the same space of time, in which the Ball hath been moved towards the right from A, one of the Points of the line AC, into B, one of the Points of the line HB, it must move from the lines HB, to some point of the line FE. For all the Points of this line FE, have in this respect the same Distance from HB, as all the Points of the line AC, and it is also as much determined to move that way as it was before. Now so it is, that it cannot arrive at one and the same time to any point of the line FE, and to some point of the circumference of the Circle AFD, save only at the point D, or at F, because there are none but these two, where they intersect one another: So that the Earth hindring it from passing towards D, we must conclude that it must infallibly move towards F. And thus you may easily see how Reflection is made, to wit, according to an Angle, which is always equal to that which is call'd the Angle of Incidence. As if a Ray, coming from the point A, to fall upon the point B, on the surface of a flat Looking-glass CBE, should so reflect toward F, that the Angle of Reflection FBE, be neither greater nor less, than the Angle of Incidence ABC.

V. Yet it is not necessary that the Angle of Reflection, should be always equal to the Angle of Incidence, forasmuch as sometimes it may be greater and sometimes less. For suppose the Body A, to descend by the line AC, towards the Body DE, and to reach the Center C, in the space of one Moment; and that the swiftness of this Motion,

be diminished one half in the Point of Contact C; Figure it is evident that the Body A, being reflected from the opposite Body DE, in its Center C, cannot in one moment run through an equal line, since it is supposed to have lost one half of its swiftness, and therefore spending two Moments, in running through an oblique line, it will by Reflection arrive at the Point of the Circle B, and will there make the Angle of Reflexion BCE, less than the Angle of Incidence ACD. This Reflexion is commonly call'd from a Perpendicular, because the line of Reflection BC doth more deviate from a Perpendicular, than the line of Incidence AC.

VI. But if the Body B, be carried to the opposite Body DE by the oblique line BC, and arrive at the Center C, in the space of two Moments, and that its Motion be encreased in the point of Contact, so as to become twofold swifter, it is evident that the Body B, rebounded by the opposite Body DE, must in the space of one Moment, in its ascent run through an equal oblique line, and arrive at the point A of the Circumference of the Circle; and so the Angle of Reflection ACD, will be greater than the Angle of Incidence BCE. And this Reflexion is call'd Reflexion to a Perpendicular, because the line of Reflection AC, doth less deviate from a Perpendicular than the line of Incidence BA.

What has been said is sufficient to explain the nature of Reflection: We proceed now to Refraction, which is when a Body passing from one Medium to another doth deflect from the straight line it described. So that by the Refraction of Motion nothing else is understood, but the Deflection or turning aside, which a Body suffers in passing from one Medium into another. For the understanding of this Refraction, we are to consider, first, whether the second Medium resists the Motion more or less than the first, and whether the Body moved do meet it directly, or obliquely; for if it meets it directly, whether it resist more or less, it is without doubt, that the Body moved must in no wise change the determination of its Motion, in penetrating of it.

To prove this, let us suppose the Body L descending in the Air by the Perpendicular line LB, and that it directly meet the Water which is under the surface CBE, which separates the two Mediums: This being so, I say that the Body L having pierced the surface CBE, will tend directly towards G, because the Water that is under that surface, doth resist it equally on all sides, and that there is nothing but the inequality of that resistance, that can make it turn aside.

On the contrary, if the Body moved meets the second Medium obliquely, then of necessity it must deflect either to the right or left, according as the second Medium resists its Motion more or less than the first; as by example, let us imagine a Ball struck with a Racket from A, obliquely to B, to meet there not with the Earth, but with the Water, whose surface is bounded with CBE, the Ball in this case doth not directly tend to D, but towards I, and this bending or deflection, which is measur'd by the Quantity of the Angle BDI, is call'd Refraction.

The Cause of this Refraction is the Resistance it meets with: For seeing that every thing as much as in it lies continues always in the same state,

VI. When the Angle of Reflection is greater than the Angle of Incidence

VII. What Refraction is, and how it is made.

VIII. A Body directly falling into a medium suffers no Refraction. Figure 14.

IX. But if it falls obliquely it is refracted.

X. The cause of Refraction.

we

we can give no reason why any *Body* should deflect from the *Straight* way in which it began to move, but because it meets with some hindrance in that part from whence it rebounds. Thus when the *Body* A, after it is arriv'd to the *Point* B, is turn'd aside, and tends towards I, we must conclude that it meets with more resistance towards the left side of B, than on the right; and if it be turn'd aside towards D, that it finds a greater Resistance from the right side of B, than from the left. And therefore if we perceive that the *Water* doth more hinder the motion of the *Ball* than the *Air*, we may easily judge that the *Ball* which in the *Air* is moved from the *Point* A to the *Point* B, that from thence it may pass into the *Water*, must pursue its course towards I, and deflect from a Perpendicular.

This may be apply'd to all *Bodies* and all the *Mediums* they pass through. Wherefore this may pass for a *Maxim*, that as often as a *Body* moved, passeth from one *Medium* into another, that doth resist it more, it must be refracted, by declining from a Perpendicular. And that on the contrary, when it passeth from one *Medium* to another where it finds less Resistance, there it must deflect towards a Perpendicular.

XII. I have already said that it is necessary to Refraction that the *Body* fall obliquely upon the surface that separates both *Mediums*, that so it may be deflected or turn'd aside. For if it should proceed Perpendicularly, without any Declination, seeing it would not be hindered on the one side more than on the other, from proceeding in a straight line, it could not suffer any Deflection, and consequently must continue its right motion, as hath been said.

XIII. To Determine the Quantity of Refractions, we must attend to the particular constitution of *Bodies*, whether they do more or less resist the passage of *Bodies* moved. For suppose we that the line CBE separates two *Mediums*, the upper whereof is *Air* and the undermost *Water*, and that the *Water* doth as much again as *Air* resist the motion of the *Ball* A. Suppose we likewise that the *Ball* A, having past the oblique line AB in one moment, to meet with the *Point* B, there obliquely to enter the *Water*: And that neither the Bigness, Weight, or Figure of the *Ball* do hinder it from so doing; Yea, and that its motion in the *Air* hath been always equal, and that having lost the one half of its swiftness, by meeting with the *Water*, it loseth now no more throughout its whole Course, how deep soever it may enter the *Water*; because this is nothing to the purpose, since the Deflection happens only in the Surface, and the *Water*, which resists equally on all sides, can only make the *Ball* to spend a greater or less space of time in its motion, but cannot make it to deflect from the Line, which it had begun to move in.

XIV. These things being observed, that we may know what way the *Ball* A must take, we are to consider that tho' the motion of the *Ball*, be lookt upon as simple, this doth not hinder but that its Determination in the line AB, with respect to the Surface of the *Water*, is compounded of two other motions, the one whereof presseth it from AF to CE, and the other at the same time presseth it from the left AC, to the right FE, so that both these together lead it to the *Point* B, by the right line AB.

Moreover we are to observe, that of both these Parts, whereof we understand that this Disposition consists, the one only is changed by the Surface of the *Water*, viz. that which drives the *Ball* downwards, whereas that which pulseth the *Ball* towards the right hand continues still the same.

Having therefore described the Circle AFD from its Center B, and having describ'd upon CBE three Perpendicular Lines AC, HB, FE, so as that the space between them FE and HB, is the double of that which is between HB and AC, we shall find this *Ball* will go on to the *Point* I: for seeing that the Surface of the *Water* CBE, doth exactly take away one half of its swiftness, it must take up a double proportion of the time in which it passeth from A to B, in passing from B to any point of the Circumference AFD. And seeing nothing is lost of the Disposition whereby it was carried towards the right hand, in the double proportion of that time, wherein it proceeded from the line AC to HB, it must go twice the length towards the same part, and consequently approach to some point of FE at the same Moment in which it draws near to some point of the Circumference of the Circle of AFD, which would be impossible if it did not advance to I.

We are also to take notice that the more obliquely a *Ball* dasheth against the Surface of the *Water*, the more it is turn'd aside by it; so that if it be directed to right Angles, as if it were struck from H to B, it proceeds in a right line without any Declination to G, as hath been said already. But if it be driven along by a right line, as AB is, and lie so obliquely on the Surface of the *Water* CBE, that the drawn line FE, cannot intersect the line AD, then will it not penetrate the *Water*, but will rebound from the Surface B into the *Air* towards F, after the very same manner as if it had lighted on the *Earth*. As we see in those Stones wherewith Boys make Drakes in the *Water*; and as *Bullets* which (according to the Relation of those who have been in Sea fights) being obliquely shot out of Cannons rebound from the *Water*, and hit Men standing on the Decks.

CHAP. XX.

Of the Force of Acting and Resisting.

THE force of acting and resisting may be understood two several ways, either Metaphysically, for the Faculty or Power which any thing hath to act or resist. And this is nothing else but a Non-Repugnance to act or resist. So he who saith that a Needle can prick, thereby means nothing else, but that Pricking may Coexist with a Needle. Or else it may be taken Physically for Reaction, as when any thing that is moved upwards, is driven down by some other Cause, and thus resistance is called Positive; as when two *Bodies* in motion, meeting together, beat back one another; as two *Bullets* or *Bowls* meeting together, by their contrary Determination. Or it is also precisely taken for the force it self of Resisting, as when a *House* resists the *Wind*, or a *Stone* the *Ball* that is cast against it. And this is commonly called Negative or Formal. And it is of these two that we enquire here, viz. to know wherein the force a *Body* has to act upon another, or to resist it, doth consist.

XV. Where the variation is in the Body moved.

XVI. How much the Ball's motion is fore-slowed when it passeth through the Water.

XVII. The more obliquely a Ball falls on the Water, the more is it deflected.

I. The force of acting and resisting taken in a twofold sense.

II.
Wherein
the Power
of Acting
or Resisting
doth con-
sist.

All the Power any *Body* hath to act upon another, and every Faculty, whether *Positive* or *Negative*, of any *Action*, consists in this alone; That according to the forementioned Law of Nature, Every *Body*, as far as in it lies, continues in the same state wherein it is, whether in *Rest* or in *Motion*; because every state of *Bodies* may be referred to one of these. So that those *Bodies* which are joyned together by *Rest*, have a power to hinder themselves from being separated, as well as those that are separated, have a Power to continue so; and they that are moved, have a Power to continue their *motion*, according to the same degree of *Swiftness*, and towards the same *Coast*: As that which *Rests* in any place, hath a force to abide there, and to preserve its *Rest*. And this is the only cause of the *motion* of *Things* that are cast or thrown into the *Air*; concerning which we have more reason to enquire how they come to cease from *motion*, than how they continue it so long as they do.

III.
This Force
ariseeth first
from the
Bigness of
the Body.

Now this *Force* may be attributed to several Particulars: As first, to the *Magnitude* of the *Body* in which it is found. For it cannot be questioned, but that a *Great Body* exceeds a *Less* in the faculty of *Acting* and *Resisting*, because in regard to the *Parts* of which it is compounded it hath more *Motion* and *Rest*; and seeing every *Body* hath a proportionate Affection answering it, therefore the *Quantity* of these must be answerable to the *bulk* of the *Body*. Hence is that common Saying amongst *Naturalists*, that a thing of greater *Quantity*, hath the greater *Virtue*: Which *Virtue* is to be esteemed according to the force of *Motion* that is in the whole *Body*, or its firm adhering and abiding in a place. Thus *Fire*, the more it is extended in *bulk*, the more violently it burns; and the more fixedly any *Bodies* continue in one place, with the greater difficulty are they thrust out of it. Thus *Round Bodies* are the strongest both in *Action* and *Resistance*, as appears in *Pestils*, *Milstones*, *Cylinders* or *Rolling-Stones*, and other such like *Instruments*, which are the more proper to bruise *Bodies*, and making them smooth or even, because their force is altogether directed to one *Line*. Thus also a *Hammer*, with a long *Handle*, strikes the *Anvil* with a greater force than that which hath a short one.

IV.
Secondly,
from the
Bigness of
the Surface.

The Power of *Acting* and *Resisting* is also taken from the largeness of the *Surfaces* of *Bodies*; for the broader the *Surface* of two *Bodies* is, the more firmly do they cleave together; as appears in two *Wooden-boards*, well plained, lying upon one another: Whereas on the contrary, where the *Surfaces* are narrow or little, by so much the less firmly they stick together. Thus *Spherical Bodies* less stick together, because their *Surface* is the least of all *Bodies* with respect to their *bulks*, and they touch each other only in a *Point*. And certain it is that *Lead* made up into a great *Bullet*, is more solid than that which is distended into a thin *Plate*, or made hollow. Wherefore the greater quantity of *Matter* is contained under a little *Surface*, the more solid it is, and of the greater efficacy to resist; as is evident in *Gold*, *Lead*, *Iron*, and other *Metals*, which being once put into *Motion*, retain a greater force to preserve and continue it, than either *Wood* or *Stones* of the same *bulk* or figure. But on the contrary, *Triangular Bodies*, and such

as have more *Surface* than other *Bodies* proportionably to their *Extension*, are more difficultly moved, and have less force to continue the same, or to resist other *Bodies*.

The said Faculty of *Acting* and *Resisting* may likewise be estimated, from the *swiftness* or *slowness* of *Motion*. For a little force resists *Bodies* that are swiftly moved; as when we lash the *Water* with a *Rod* or *Wand*, we find the *Water* to resist the *Rods* entrance. Because (as hath been hinted heretofore) the Strife of *Material things* in *Acting* and *Resisting*, depends on the determination of the *Motion* towards some certain *Part* or *Coast*, and its meeting with a *Body* resting there, or otherwise moved. And a *Body* is then taken to be otherwise moved, when it is either moved more slowly, or another way.

This *Force* may also be gathered from the nature and contrariety of the *Mode* or *Manner* whereby divers *Bodies* meet with one another. For according as they are variously oppos'd to each other, so they have a different force of *Acting* and *Resisting*. Thus a *Stone* flantingly thrown on the *Surface* of the *Water*, so as to leap from it, cannot divide the *Top* of the *Water*, as if it had been downright cast into it.

From these Four Particulars, to which all *Action* and *Resistance* of *Bodies* may be referred, we may determine how *Bodies* do increase, or diminish their *Motions*, or change the determination of them, (for there is this threefold difference in *Motion*;) only we are to observe how much *Force* there is in every *Body*, either to move or resist *Motion*, and certainly conclude, that that which is strongest, always takes effect. Thus the *Motions* of *Great Bodies* have their *Force* from the Agreement of their *Parts*, though their *Motions* have but few degrees. So *Stones*, and even large *Buildings*, are oft forced to give way to a *River* that runs but slowly. And upon the same account, in other *Bodies* also the *motion* may be strong, tho' it be not swift: And on the contrary in less *Bodies*, there may be a considerable swiftness of *motion*, and not any great force. As if the *Body A* (for Example) should be moved as swiftly again as *B*, and the *Body B* should exceed *A* in bigness in a double Proportion, in this case we must estimate as much *Motion* to be in one, as in the other; because the Extrusion which is found in the *Greater Body*, is by its *bulk* equivalent to the Intension of *Motion* in the other.

Now in the opposition or meeting of *Bodies*, this Rule always holds good; Whatsoever exceeds another thing in strength, obtains its effect, whether it be in moving another *Body*, or in resisting its *Action*. And therefore of those things that tend to the same place, if it be not large enough to contain them all, the strongest only do get thither, leaving the weaker behind them. Thus the most lively and vehemently moved *Particles* of the *Blood* are received into the Cavities of the *Brain*, the weaker being hindered by the stronger from arriving there; because the Passages of the *Brain* are too narrow, than that all the *Particles* of the *Blood* can get up thither.

V.
Thirdly,
from the
Swiftness
of Motion.

VI.
Fourthly,
from the
Meeting of
Bodies.

VII.
A threefold
Difference
is incident
to Motion.

VIII.
That which
is strongest
always ob-
tains its
effect.

C H A P. XXI.

Of the State of Bodies; and first those that are Hard, Fluid, Frangible, Friable, Soft, Ductile, and such as may be cut or slit.

AMongst the Principles of Natural things, MOTION and REST only are opposed to each other, not privatively (as some would have it) but contrariously, as two Modes really distinct. For Rest or Quiet is not a Privation of Motion, but a true Form, whereby Stable and Hard Bodies are distinguish'd from such as are Fluid, and whence they receive the force of Acting and Resisting. For those Bodies are accounted Hard, whose Parts by a firm Union lye still together; or whose Parts do so closely cleave together, that they cannot without difficulty be separated. Which close Union is perceptible to the Senses; for if we touch any of these Hard Bodies with our Hands, or any other part of our Body, they resist them, and oppose their entrance; as we see in Marble, Wood, Stone, &c. for if, when they are handled by us, they give way, we should perceive no Sense of Hardness at all; as appears by the Air, which is not felt by us, because it gives way to our touch.

II. The Hardness of Bodies is various, according to the variety of Rest; for wheresoever there is more of Rest, there also is more of Hardness; and so contrarily. Clay, when the Water is evaporated from it, grows hard, because the Rest of its Parts is by this means increased, its Earthy parts being delivered from the Agitation of the Fluid parts, interpos'd between them; whereas Wax being heated, becomes soft, because the Rest of its Parts is lessened, by reason of the Oily Particles, which being benum'd before, are by the Heat put in motion.

III. When we say that Rest is the Cause of Hardness, we mean the Formal, not the Efficient Cause; for the Efficient Cause of Hardness consists only in the force wherewith the Air, or other Subtil Matter, compresseth the Parts of Hard Bodies. To the end therefore that we may have a distinct Idea of Hardness, we must conceive it to be nothing else, but the Rest of many parts of Bodies, caused by the Pression of the Air, or the Subtil and Aethereal Matter, which acting from without, drives these parts inward in such a manner, that they cannot be separated afterwards, without making us sensible of their Resistance.

IV. Fluid Bodies, on the contrary, readily yield to the motion of other Bodies, and therefore do not resist our Hands when we touch them, as appears in the Water and Air. The Cause of which difference consists only in Rest and Motion: For if we enquire why some Bodies cannot but by force be thrust out of their places; whereas others without any difficulty yield the place they are in possession of, to others, we shall find that the Reason is, because their Parts, which resist those Bodies that approach to them, lye still and Rest; whereas the Parts of other Bodies, that without any force do leave their places, are in motion. So that Hard Bodies are such, whose Parts lye still and cohere together; but Fluid Bodies are divided into many little Parts, which are variously moved. For the Parts of Water, or any other Liquor, are

agitated every way by the Subtil and Aethereal Substance: And accordingly those Bodies are called Fluid, whose Insensible parts have such various Motions.

Now that the Parts of a Fluid Body are moved, and that equally every way, appears from hence, that in what part soever of a Fluid Body we do move our Hand, or a Stick, it always goes on with the same easiness, which could never be, if the Determination were stronger one way, than it is another. Tho' it cannot be deny'd, but that some Resistance is found in a Fluid Body, if we swiftly lash any thing against the Parts of it; because a Body slowly moved, comes under the Notion of a Body at rest, when compared with a Body that is much more swiftly moved, and consequently will resist it.

Hence it is that the Figure of Fluid Bodies is undetermin'd, because they are so easily divided and diffus'd, that they cannot keep themselves in their own bounds. But Hard and Stable Bodies being hard to be divided, easily retain their Figure, and are easily comprehended within their own limits; as appears in Lead, Iron, Silver, Gold, Wood, Marble, &c. which according to their several degrees of Solidity preserve their figure and Bulk. That therefore we call a Fluid Body, whose Parts being divided into many small Particles, and these again into less Indefinitely, are variously agitated. But that is called a Hard Body, whose Parts by Rest do so closely cleave together, that they cannot be separated, but by a Force sufficient to overcome their coherence.

The smaller and lighter the Parts of any Fluid Body are, the greater is its Fluidity; and the thicker and more Branchy they are (if Contact doth not hinder) so much the less is it. Hence arise the diverse kinds of Fluid Bodies, according as by the lightness and smallness of their Particles, they are more, or according to the Thickness and Branchiness of them, less yielding to the Celestial Matter, which is the Cause of their Fluidity. Upon this account it is that the Air is more fluid than the Water; because the Parts of Water, tho' they be smoother, yet are thicker than those of the Air. And Water is more fluid than Oil, because the Parts of Oil are more thick and branchy: Lastly, Oils are more or less fluid, as their Particles are more or less thick and branchy.

When I say that the Nature of Liquid Bodies consists in Motion, it is not so to be taken, as if the whole Liquid Body were moved out of one place to another, for this happens also to Hard Bodies: For a Bowl of Brass is easily row'd from one end of a Table to the other, and for all that persists to be a Hard Body; but in this, that the Particles into which they are divided, are moved and variously agitated, some of them being tost to the Right, others to the Left; some upwards, others downwards; some forwards, and others backwards: Which Motions of the Particles must be different. For if they were all of them carried one way, they would in a short time cling together, and make up a stable or hard Body.

And tho' the Course of a River be directed to one particular part of the Land, it does not therefore lose the Name or Nature of a Fluid Body; forasmuch as the various Motion of the Particles of the Water is preserved, notwithstanding the

V. How it appears, that the Parts of Fluid Bodies are agitated every way.

VI. Fluid Bodies have no certain figure, as Hard Bodies have.

VII. The various kinds of Fluid Bodies.

VIII. How Fluid Bodies are said to be in Motion.

IX. Why Ice is carried with a greater Force, than the Water.

said Course of the *River*, as much as in a still *Standing Water*. Hence it comes to pass, that *Ice* driving on the top of the *Water*, because of the firm clinging together of its *Parts*, doth with a greater force pursue its way, and with more violence set against the *Banks*, than the *Water* it self which carries it; because the *Parts* of *Water* being tost with various *Motions*, weaken the force of it, and therefore cannot tend with that vehemence to one part, as the *Ice*, which is a *solid Body*, doth. By which Example it is evident, why *Fluid Bodies* easily give way to other *Bodies*, but *solid Bodies* not; because *Fluid Bodies* are always in *Motion*, and therefore do not oppose the entering of other *Bodies* into the places they are in, but readily and easily quit them. Whereas *Hard Bodies* rest, and according to the *Law* of *Natures* immutability, strive to continue in the state of *Conjunction*, except they be disturbed by some strong *Motion*.

This Sentiment will not please some *Philosophers*, who suppose no two *Bodies* can be joyned without some intervening *Third*, distinct from them both; which they imagine to be as the *Glew* that holds the parts together, that the *Union* may be the more firm. But since nothing is to be admitted in *Natural Philosophy*, which we are not convinc'd of by *Reason*, we must consider first, what kind of *Glew* this can be, before we appropriate it to this use. Without doubt it must be either a *Substance*, or the *Mode* of a *Substance*, seeing that amongst *Natural things* nothing else is to be found besides *Substances* and their *Affections*. If it be supposed to be a *Substance*, it cannot be understood why the *Parts*, which because they are *Substances*, cannot be united by themselves, should yet stand in need of an adventitious *Substance* to unite them. If it be a *Mode*, then without doubt none can be more properly assign'd to this purpose than *Rest*, since that which makes the *Parts* to be united together, must be most oppos'd to *Motion*, by which they are divided from one another. For *opposit Things must have opposit Principles*; but nothing is more contrary to *Motion* than *Rest*, as being the contrary *Affections* of *Material Substances*.

XI. You'l say, *How may we know that the Parts of Fluid Bodies are in continual Motion?* I answer, That tho' the smallness of those *Particles* doth not permit us to discern their *Agitation*, yet may the same be easily discovered by the *Effects*. There is no body but perceives, that some parts of *Water*, evaporate in *boiling*, and that in the *Summer* time *Ponds* are lessen'd or dryed up, which could not be, but that some *Parts* of the *Water*, being separated from one another by *Motion*, steam away into the *Air*. Moreover, how else comes it to pass that the *Particles* of *Water*, do so readily mix together? Or, how could they insinuate themselves into the *Pores* of *thick Bodies*, if their *Parts* did cling together by mutual *Rest*?

XII. For the *Division* of *Parts* depends on their *Motion*, *Agitation* being that which separates one thing from another. This is very evident in *Flesh*, which is soon corrupted by the *Air*, the *Particles* whereof being agitated either by the *Sun*, or some other way, thrust themselves into the *Pores* of *Flesh*, and by dilating of them and spoiling their *Natural* situation, do at last dissolve and putrifie it. The ready and thorough mingling of *Liquors* discovers the same thing, it being evident that this

easy mingling cannot be done without *Motion*, whereby the *Parts* of two *Liquors*, as for Example, *Water* and *Vine*, run together.

Besides, what *diversity* would there be amongst *Bodies*, if all their *Parts* lay still together, and were equally united? *Cold water* would not differ from *Ice*; *Crystal* and *Milk* would be the same thing; nor would any Cause be assignable, why *Crystal* resists our touch, or why *Milk* yields to the approach of *Hard Bodies*.

Wherefore we may conceive twofold *Parts* in *Liquid Bodies*; some at it were *flying*, by reason of their swiftness, such as the *Parts* of *Smoke*, the *Steam* of *boiling Water*, and *Flame* are, which are tost so forceably that our *Senses* can discern their *motion*. And others, as it were, *creeping*, because of the slowness of their *motion*; as the *Particles* of *Oil*, *Milk* and *Vine*, whose *motion* is so slow and leisurely, that our *Senses* cannot perceive it. So that when it happens that one *Liquid Body* is not sufficient to dissolve another, or that it can exercise its force more upon one *Body* than another; the Reason thereof chiefly is, because its *Parts* are more or less agitated, or because the *Pores* of those *Bodies* are not open alike.

Soft Bodies approach to the Nature of *Liquid*, and are such whose *Particles* do not cling so close and firmly together, as the *Parts* of *Hard Bodies*, nor are agitated with so swift a *motion* as *Fluid Bodies*, but partake of both their *Natures*, being middle things between *fluid* and *stable Bodies*, such as are *Sand*, *Wax*, &c. The softness of *Sand* is caused, for that something intervenes betwixt their separated *Parts*: And *Wax* is soft, because its *Particles* terminate in flexible branches, which twisting together lightly, joyn the said *Parts*.

Of *Hard Bodies* some are *Frangible*, others *Friable*. For whatsoever can be broken must have such a degree of stiffness, that its outward *Parts* when struck, may be neither dilated, nor admit any ingress of *parts* into *parts*; but that the *surfaces* being broken, the *inward parts* likewise be divided and broken asunder. Of which Nature are *Flints*, *Earthen Pots*, *Stones*, and the like, which according to the diversity of their contexture, are more easily or hardly broken.

Thus *Friable Bodies* must have so much stiffness, that they cannot be stretched or bended; but upon any force pressing upon them, do crumble into *Dust*. Of which Nature is the *Sand-stone*, which is easily dissipated into small *parts*, and those again easily crumbled to *Dust*.

Amongst *Soft Bodies* are reckoned those that are commonly called *Ductil* (that is, *Bodies* that suffer Drawing or Extension) such as *Gold* is, one *grain* whereof may be drawn into a *Thread* of four hundred Foot long; and consequently one *Ounce* to the length of 230400 Foot. The Cause of which vast discussion is commonly attributed to its extream *Compactness*, the *Thinness* of its *Parts*, and their intimate *Union* and *Connexion*. Of which we shall speak more at large hereafter.

Some reckon *Bodies* that may be cut or slit, also amongst *Soft Bodies*; because whatsoever is cut, must have so much flexibility, that the *Part* which is prest (suppose with an *Ax*) can give way downwards, at the same time that the *Collateral parts* yield to the dividing *Instrument*. And whatsoever can be slit, must be so flexible or bending, that

XIII.

Bodies would not be distinguish'd from one another, if some were not moved.

that when the *Parts* in a certain place, begin to be pull'd asunder, a Compression may be successively made, in whatsoever places the rest are to be gradually separated from each other. *Wood* is said to be Cut, when it is divided *Cross-wise*; but to be slit, when divided *Long-ways*, or with the *Grain*.

CHAP. XXII.

What Loose and Close, Rough and Smooth, Contiguous and Continuous Bodies are.

I. Whence proceeds the Looseness or Closeness of Bodies.

AS *Stable* and *Fluid* Bodies are constituted such by *Rest* and *Motion*; so *Loose* and *Close* Bodies are made such by their *Figure* and *Situation*, not outward, but inward. For the *Looseness* or *Closeness* of Bodies, is not to be considered according to the outward Space in which Bodies are dilated or contracted; seeing that a Body, whose *Essence* consists in three *Dimensions*, cannot take up a greater Space at one time, than at another; but according to the *Intervals* which are understood to be betwixt their *Parts*; and which are said to be *distended*, when they are fill'd with any foreign Matter; or to be *contracted*, when by Removal of that Matter, they are either lessened, or quite taken away.

II. Loose Bodies are made such, by the Ingress of Matter; Close Bodies by the Egress.

For we must not imagin, as many do, that the parts of Loose Bodies are so separated from one another, that nothing extended comes between them; For no such *Vacuum* can be in Nature; but that the said *Intervals* are fill'd with other Bodies; as is apparent in *New-bak'd Bread*, which being put into *Milk* or *Vine*, presently swells up into a much greater bulk; because the Pores of the Bread are distended by the intruding particles of the *Vine* or *Milk*. So that all the New Extension we find here, is not to be attributed to the Substance of the Bread, but to the fluid Body that hath insinuated it self into the pores of it. Which is evident not only to Reason, but to the Senses themselves: For if a man behold the *Steam* that riseth out of a Pot of *boyling Water*, or the *Smoke* that proceeds from a *Torch* at a distance, he will suppose the parts of them to be contiguous; but when he comes nearer, and views them more wishly, he will find that there is neither *Continuity* nor *Contiguity* between the parts of them, but that they are separate from one another, by means of a foreign intervening Matter that divides them.

III. Examples of Loose and Close Bodies.

A Body becomes close, when the parts of it being nearer together, leave few *Intervals*, or none at all. Of the first sort are *Snow*, *Hay*, and *Wool*, when they are compress'd, as also a *Sponge*, when the Water is squeez'd out of it; for then by the expulsion of the *Liquor*, its Pores are narrowed, and few *Intervals* are left in it, to receive any outward Bodies. Of the latter sort are those Bodies, which have no Pores at all into which any External Body can enter; and when it is so close, then it cannot be further condensed by any Power of Nature.

IV. What Rough and Smooth Bodies are.

As with respect to the Figure and Situation of its Inward parts, a Body is distinguish'd into Loose and Close; so with regard to their Outward figure and situation, Bodies are said to be *Rough* or *Smooth*. Which Modes are of great efficacy in Natural things; as appears in a *Knife*, wherewith the Hardest Bodies are cut; and in a *Pen*, with which an infinite variety of Characters may be made.

Rough Bodies are such whose superficial Parts are unequally disposed, so as that some are prominent and others deprest; as *Rusty Iron*. But Smooth or Polish'd Bodies are such, whose Extream parts are equally situated, as *Ice*, a *Whetstone*, &c. Smooth Bodies, because of their Surface, have more force to Act or Resist, than Rough Bodies. For a *Sword*, whose Edge and Extream parts are polish'd and even, cuts deeper than another *Sword* of the same bigness that is *Rusty*; and a *Ball* rebounds more strongly from polish'd Bodies, than from rough.

Yet we are not to imagin, that all those Bodies in which neither our Touch nor Eyes can discover any inequality, are altogether smooth; forasmuch as even *Glass* and *Crystal*, which appears very smooth, have a rough Surface. For tho' *Glass* be made of *Salts*, which by Melting are resolved into very small Particles; yet because those Particles still retain their former figure, they can never make a polish'd Surface. What appears to our Eye more smooth than *Paper*? And yet by the help of a *Magnifying-Glass*, we perceive it to be very rough and uneven. Hence it is manifest, that in what part soever of the Medium the Eye be placed, it receives the various Rays, which come from and represent the Object.

The two Remaining Species of Bodies are Continuous and Contiguous. A Body is said to be Contiguous with respect to the situation it hath amongst other ambient Bodies. Thus a *Tree* surrounded by the *Air*, is said to be Contiguous to it. And accordingly a Contiguous Body is thus defin'd by *Plato* in *Parmenides*: That which is to touch something, plac'd by it self, must be next to that which is to be touched; neither is there any Third thing that is a Medium between both these. A Continuous Body is that which besides the situation it keeps amongst Circum-ambient Bodies, becomes united to them; and by Rest is joyned with them. Thus a *Stone* is said to be a Continuous Body, being considered whole and undivided; and before any change happen to it by Motion. But this Contiguity of Bodies is not in all their parts; but only in those that are Insensible, since such only have an immediate Contact with one another.

The Continuity therefore of Bodies consists in this, that their parts do cleave together by an Immediate Connexion, and rest together. So that Continuous Bodies cannot be dissolved, but by such a Motion as prevails over the Rest of their Parts. The Contiguity of Bodies consists in this, that their Extream parts lying still together, nearly touch one another, yet so as that a most thin subtil Matter flows and runs between them; and by reason of this Interfluent Subtil Matter, the parts of Contiguous Bodies are more easily separable.

CHAP. XXIII.

That there are Pores in Hard Bodies, as well as in those that are Fluid and Soft.

THO' it is not denied, but that the World was Created in the Beginning with all that Order and Beauty which we find it to have at present, and that all the Bodies contained in it had the same perfection which we see they now have;

V. All Bodies are not Smooth, which appear to be so.

VI. What a Contiguous and Continuous Body is.

VII. Wherein the Nature of Contiguity and Continuity consists.

I. Supposing Bodies to be moved, it is necessary that yet there be

Intervals
or Passages
left between
them.

yet in order to our more accurate understanding of the State of Bodies, it will be of use at first to consider all Matter as one undivided Lump or Mass, and afterwards conceive the same distinguish'd into parts, by the Motion impress'd upon it by God, out of which Parts all Bodies are made. For by making this Supposition, the Constitution of Bodies is the better conceived; and the Connexion between the several Parts, will the more plainly appear. For these Particles having obtain'd various Figures by means of Motion, it was not possible for them to be so united together, as that no Intervals should be left between them, to be fill'd by some other Subtil Matter. These Intervals we call Pores, which do arise from the various Conjunction of little Bodies or Particles.

II.
How Pores
come to be.

First, When the parts that stick together are Round; for since these, by reason of their Convex sides, can only touch each other in a point, they must necessarily leave little Intervals between them. In the Second place, when those parts have irregular Figures; for then by reason of their various Termination, they cannot so intimately close together, but that some little Spaces must be left between them. Thirdly, By the Force of the Subtil Matter, which being excessively Active, by separating joyned Bodies, makes way for it self to penetrate them. Which Irruption of the Subtil Matter is very frequent in Soft and Fluid Bodies; because, as hath been said, they give easie admittance to other Bodies, and by their Motion do assist their Impulse. Hence it is that the Fluid Matter, which consists of Round particles, is accounted the most Porous. For tho' little Globular Bodies are very proper to compose a Liquid Body; yet because of their Figure, it is necessary that Triangular Spaces be left between them, not empty, but fill'd with the Matter of the First Element. Thus we see, that the Light of the Sun does come to us, through the Spots with which it is surrounded; which could never be, but that they abound with Pores, which afford passage to the Matter of the First Element.

III.
How Pores
are come
to be in
the Spots
that are
about the
Sun.

These Pores are easily conceived to have been made at the first beginning of their Generation, viz. when the Matter of those Spots was as yet very Loose and Soft; and when afterwards it became more Close and Compact, the particles of the First Element, by passing through them continually, kept them from being quite closed; tho' they were so far narrowed, as to admit only that Subtil Matter.

IV.
If there
were no
Pores, there
could be no
distinction
between
Bodies.

And the same Reasons prove, that there must be Pores in all other Bodies, except those only whose parts do so intimately touch one another, that they can be no further comprest or condensed; for such as these are the hardest Bodies of all, as being devoid of all Pores whatsoever. But should we suppose this to be the condition of all Consistent Bodies, we should by this means take away all distinction that is between them; as for Example, between Wood and Stone, between Crystal and Earth; since between them there would be no distinction, as to their Inward Figure and Situation, and consequently all Bodies, as to their Inward parts, would be alike; which is the same as to say, that all Bodies are Close, and that none of them are dilated by admittance of the Subtil Element.

But since the Difference of Bodies is apparent to the very Eye, some of them being Living Bodies, other Lifeless; some Transparent, others Dark; it is necessary that there be a difference between them with respect to their Inward parts. For if we deprive Hard Bodies of their Pores, we shall never be able to understand how Plants are nourished and grow, since this cannot be without the receiving of Juices, whereby their Parts become dilated and extended. For according to the diverse disposition of the Pores of Trees, their Growth and Nourishment is also different. Thus we see that an Oak and a Medlar Tree, with other such like Plants, because of the Hardness of their Sides, and the narrowness of their Pores, do grow more slowly; whereas a Vine, a Gourd, and other such like, whose Pores are wider, grow very swiftly and spread their Branches far and near.

That this is so, is evident in the Winter; for then all Budding and Growth is hindred, because the Pores at that time, by the Suns departure, being closed by Cold, cannot admit their Food, as they were wont.

The Existence of Pores is prov'd likewise by that Experiment which was made in presence of the Great Duke of Florence, which was as follows: A Glass Vial, with a long and narrow Neck, was put into warm Water, almost up to the middle of the Neck; after a small time the Liquor contain'd in the Vial seem'd to fall down a little; but to rise again to its former height, when the said Vial was put into cold Water. Because the Pores of the Glass being enlarged by Heat, procure it a greater Capacity; whereas, when the Pores are straitned by the cold Water, the capacity of the Glass grows less, which is the cause of the Rising of the Liquor.

Moreover, we daily experience, that a Bow when unbent returns to its former figure, which Return cannot be attributed to any Cause, save only to the bending of the Pores. For the Subtil Matter which was us'd to pass through those Pores, now by reason of the bent of it, is not able to pass through them with the same ease, and therefore endeavours to reduce them to their former figure. Which may be done several ways. For if, First, we suppose that the Pores of the unbent Bow, in their Natural posture, are of the same wideness at their entrance and ending; but that when bent they become more narrow at the end, it cannot be doubted but that the Subtil Matter, which enters the wider parts of them, will put a force upon the more narrow parts, and thereby cause the Bow to fly back. Secondly, If we conceive the said Pores of the Bow, before Inflexion, to have been Round; and that by the bending they became Elliptical, the Subtil Matter that is to run through them being Round also, it is evident that whilst they endeavour to enter those Elliptical Cavities, they strive to reduce them to their Spherical Figure; which is the Cause why the Bow flies back to its first state.

But to return from this particular Example, to the consideration of Pores in general; we say, that all Bodies that have like Pores, are like to one another, if withal they agree in the same Quantity, Motion, Rest, Figure and Situation of Parts. For diverse Matter requires diverse Pores, seeing it is necessary for it to be differently constituted as to its

little Particles, to the end it may be able to exert its Force; and to thrust it self into other Bodies. But yet we are not to imagin, that all the Pores of Consistent Bodies, have their Pores hollowed after the same manner, or disposed in the same situation and figure: For they who in Winter time put on a Waistcoat over their Shifts, find themselves less subject to Cold, than when they wore nothing besides their Shirts; which would not be so, if the Pores of the Shirt and Waistcoat did answer to one another in their figure and situation.

X
How the Pores of Bodies come to be destroyed.

As Pores do arise by the Generation of Bodies, so by their Dissolution they are destroy'd. Thus the Pores are destroy'd in Wood that is worm-eaten, and in Clothes that are Moth-eaten. Or if the Pores be wider, as in woollen Cloth, and other such like, they may happen to be divided in the midst, and afterwards be made whole again by being joyn'd to other Pores of a like figure. Another way whereby Pores are destroyed, is that of Obstruction, when the parts of Bodies become so closely united, as to make one Continuous Body; as when by means of Condensation the Pores are lessened, or quite taken away; or when some supervening Matter remains in them, and hinders any other Matter from entering them: So when the Pores of the Sails of a Ship are fill'd with Water, it hinders the Wind from passing through them, notwithstanding that the Wind have a far greater agitation than the Water.

CHAP. XXIV.

Concerning Duration, and its Species, Time and Eternity.

I.
Duration agrees to all existing Beings, and is only notionally distinct from them.

Forasmuch as Natural things exist; and take up certain places, it cannot be doubted, but that they are Sometime, and that they have Duration and Continuance in their Existing. For Duration is the Consequent of Existence; and whatsoever is not made, and destroyed in the same moment, must be considered as enduring, so that Duration may be defined, An Attribute under which the Existence of Created things is conceived, in as much as they persevere in their Actuality. From whence it is evident, that Duration is not really distinct from the Existence of a thing, there being only a Notional distinction between them. Because as there is no Body so little, but that it doth consist of parts, and may be measured with three Dimensions; so there is nothing in Nature of so short a Duration, but that we can measure it; neither can any thing be taken from its Duration, but as much must be taken from its Existence.

II.
The Definition of time.

Time therefore is nothing else but the Measure of the successive Duration of Bodies, according to the equal Motion of the greatest Bodies, viz. the Sun, Moon, &c. Aristotle defines Time to be the number of Motion, according to Former and Latter. But this Definition stands in need of another to make it Intelligible, except by the number of Motion according to Former and Latter, he means only thus much, that by Time we number the successive Duration of Bodies, in which there is Former and Latter according to the Motion of the Sun.

III.
The three Differences of time.

There are commonly three Differences of Time reckoned, viz. Past, which hath already been; Present, that which now is; and Future, that which shall be. By the Present time, we are not to under-

stand an Indivisible Instant; for no such can be found either in Time or Motion, the Nature of them both being successive; but all that part of Time, which the Mind represents to it self as Present: Thus we say, the Present Hour, Day, Month, &c.

From the foresaid Definition of Time, it is apparent, that Time, being the Measure of the successive Duration of Bodies, must Measure Rest, as well as Motion. For we say as commonly, that a thing hath rested, as that it hath moved so long. The same is manifest also from this Example, If a Dog, in half an hours time, run three Miles, and a Tortoise in the same time go only the length of one Pace; the Measure of the Time will be the same in both these motions, when yet there is much more motion in the Dog, than in the Tortoise. And therefore Time is nothing else, but the Duration of a Creature in whatsoever State it may be.

For we find Succession in every Created Being, and we can Measure the same by motion properly so called, or at least by the thoughts of our Mind, which seeing they do not exist all at once, must needs involve Succession. Wherefore, neither can the Duration of an Angel or the Mind of man, be said to be altogether at once, as the Duration of God is, because we clearly understand succession, both in our own thoughts, and those of an Angel; for Angels do not think all things together and at once. But such a Succession cannot be admitted in the Divine thoughts, God being an Act altogether Simple, Complete, and liable to no Vicissitude. Wherefore also Gods Eternity is his very Nature and Essence, forasmuch as he is most sufficiently of himself. And so Time is the same with the Created things themselves, forasmuch as they receive their finite perfections successively, that is, the one before the other.

You'll say, suppose a Creature should only continue one Moment, that thing would exist in the World, but without any Succession of Existence; therefore Succession is not involved in the conception of Duration.

I answer, that Duration cannot be understood without Continuation, and therefore no part of Duration can be assigned so small, but that there must be continuance in it: Since no Moment can be conceived, which is not divisible into other Moments. Wherefore those are mistaken, that make the present Time, to be an Indivisible; for since every Duration is Greater or Less, that is, consists of more or less Parts, no real Particle of it can be assigned, which hath not a quantity of its Duration distinct from another. Wherefore as every Particle of a Body, may be divided into other Parts: So likewise the present Time is compounded of Parts, and is divisible into other Moments.

Whence it follows, that Time is not an Affection of Created things, but a mere Mode of Thinking, or an External Denomination, which we call an Entity of Reason. For as Things, from the the Operations of our Mind, are said to be Known, Understood, Defined, &c. of which Operations they are only the Objects; so Time, whereby we Measure the Existence of Created things, is no more with regard to them, but an Extrinsecal Denomination, and a Mode of Thinking, made use of for the explaining of Duration. Hence LUCRETIVS saith Book I.

IV.
Time is the Measure as well of Rest as of Motion.

V.
Succession is included in every Duration.

VI.
An objection taken from a thing that exists only one Moment.

VII.
The answer that all Moments are divisible.

VIII.
Time is only an Entity of Reason.

Time of it self is nothing, but from Thought Receives its Rise, by labouring Fancy wrought From things consider'd, whilst we think on some As Present, some as Past, or yet to come. No thought can think on Time, that's still confest,

But thinks on things in Motion or at Rest:

GASSENDUS from these Verses of LUCRETIVS, concludes EPICURUS to have been of the Opinion of ANTIPHANES, who held, that *Time was something that had no real Existence, but only in the thought of Man.* which ARISTOTLE also seems to insinuate, whilst he defines *Time by Number*, which cannot exist without the understanding of the Counter or Numerator. It is not in vain, saith GASSENDUS, that EPICURUS warns us, that we are to speak otherwise of *Time*, than of other things, which are in a Subject; thereby intimating to us, that *time is in a Subject only by the help of our thoughts*; forasmuch as the Mind of Man considers a thing not to cease to be, at the same moment it begins to be, but to abide and continue, and to keep its Existence for a longer or shorter space of time. So that that it is evident that EPICURUS would not have any thing further to be inquired of *Time*; than what the Mind at first sight conceives of it, that is, a stay or continuance, whether it be longer or shorter. And if any Man should demand what *Time* is, we may answer him with DEMOCRITUS, that *Time is just such a thing, as is the space of Day and Night.*

IX.
What Duration is called Time.

Wherefore to the end we may Measure the Duration of all things, we compare it with the Duration of some particular Beings, which have a certain and most equal Motion, by which Days and Years are made, and this Duration we call *Time*. Wherefore they who suppose the Sun to be whirled about the Earth, or the Earth to turn round about its own Axis, attribute time to the motion of either of them, as being its proper Measure, according to Former and Latter: But as for the Duration of other things, they will have them to be measured by time, only by means of an external Application of our Mind. Thus when we say, that Nestor lived 300 years, we mean that he lived so long, as that Motion lasted, wherein the Sun performed 300 of its yearly Courses, or the Earth 1095 Circuits about its own Axis.

X.
How time is said to flow, or to be successive

If any one urge, that there are many things agreeing to time, which cannot be attributed to an Entity of Reason or an Extrinsic Denomination, as when we say, that *Time flies*, *Time teacheth Men many things*, that *Time comes*, *follows*, &c. which cannot be spoke of a thing that doth not exist at all, but only depends on our thoughts.

XI.
Answer.

I answer, that these are *Metaphorical Speeches*, and which agree only to the things that pass away, are taught, come, follow, &c. For Time is said to *run*, or pass away, when things by an outward Application of our Mind, with respect to the motion of the greatest Bodies, which can be observed by all Men, are understood to exist for some time. Time is said to *teach* all things, when those things which heretofore were hidden from Men come to be known; and upon the same account Time is said to *come*, to *succeed*, to *vanish*, &c.

If any Man should infer from hence, that therefore upon the ceasing of this universal and equal motion, of the Sun or Earth; Time must cease also, and be no more, because then our Mind will be no longer able to compare the Duration of Created things, with the Duration of certain equal and stable motions.

To this I answer, by denying the Consequence, because Former and Latter is not only in motion, but also in our Thinking Mind, since that in it we find a true succession of Thoughts; for we cannot at once and altogether Think of all things, we can think of. And therefore, tho' all motion should be taken out of the World, yet would not that put an end to succession, but Created things existing in our Thoughts, would be still commensurate to Former and Latter.

Having thus explained the Nature of Time, it remains that we speak a few words of the other species of Duration, viz. Eternity, which they call the Duration of a thing, without either Beginning or End, and which belongs to God alone. And which BOETHIUS defines to be, *The All at once, and perfect Possession of an Interminable Life.* The word Life is here taken for the existence of a thing, endued with all the Perfections it is capable of. The words *all at once* intimate, that Perfection does not agree to the Eternal Being successively, but that he possesseth them all at the same time. Whence we may infer, that no Creatures, whether Material or Incorporeal, could ever be Eternal, because it implies a contradiction for them to possess at once all the Perfections, Qualities and Modes which they are capable of.

From all that hath been said it appears, that there are some things whose Essential Parts, can exist together, or all at once; and that there are others to whom this cannot agree. The better to distinguish these, I call those things successive, whose Essential Parts are in a continual Flowing. Thus Time is a successive Being, because Present, Past and to come, which are the Essential parts of it, are never all at once. And I call those Permanent, all whose Essential parts are together. Thus a Triangle is a Permanent Being, because the Content and the three Sides, of which it is composed, do exist all at once, or at the same time.

CHAP. XXV.

The Ends of GOD are not to be enquired after in Natural Philosophy.

THO we own GOD to be the Efficient Cause of all things, and that all Creatures depend on him alone, yet we have no mind to enquire, for what end they were produced by God, and what Reasons he propounded to himself, in calling them out of the Abyss of Nothing. Who knows not that the Secrets of God are unsearchable, and past finding out? And as it is not the part of an Earthen Vessel, to dispute the Point with the Potter, why he hath made him such; so neither does it become Mortal Man, to question with his Maker, why he hath done so and so. And indeed this Reason alone taken from the Divine Majesty, and our Littleness and Meanness, may be sufficient to restrain us, from enquiring into the Ends God hath proposed to himself in the making of Natural things.

XII.
Whether upon the ceasing of the Motion of the great Heavenly Bodies time ceaseth also.

XIII.
Answer.

XIV.
What Eternity is.

XV.
All Beings are either Permanent or Successive.

I.
It is a piece of Rashness to enquire concerning the ends of God.

II. For tho' in the Contemplation of *Natural* *Our Human* *things*, it be permitted to us to enquire, from what *Principle* they proceed, what their *Matter* is, and with what *Forms* they are perfected; yet is it a piece of Rashness and Arrogance in us, to dive into *Gods Counsels*: Whereas we ought rather to consider that we are weak *Creatures*, of limited *Perfections*, and not fully Masters of our own *Actions*; whereas *God* on the other hand is *Im-* *mense*, *Infinite*, *All-wise* and *Omnipotent*, so as to be able to produce innumerable *things*, the *Reason* whereof could never enter into our *Thoughts*.

III. For if we are not able to give an account, of what use those *things* are to us, which in such great abundance are hid in our *Earth*, and cannot assert but that they have been destinated by their Author, to ends altogether unknown to us: How then shall we dare to pry into the *Arcana* of our most *Good*, most *Powerful* and most *Glorious* Creator? As if we were familiarly acquainted with his *Mind*, and as if we had been his *Privy Counsel-* *lours*. Is it not much better for us to adore his *Good-* *ness*, without determining of those *things*, which it is not allowed *Man* to *know*, nor permitted to search into.

IV. I own that in *Moral things*, where Conjectures are of more Authority, it may be conducive to *Piety*, to enquire into, and determine the end *God* hath proposed to himself in *Creating the World*. Therefore *Preachers* to excite the *Divine Love* in us, set before our Eyes the several uses and advantages, which the *Creatures* afford us, telling us that they were made for our *Sakes*. But in *Natural Philosophy*, where nothing is to be admitted, which is not built upon the most unshaken *Reasons* and *Arguments*, it seems to be a foolish thing to guess at any end, that *God* should have proposed to himself, in the *Creation* of the *World*.

V. But some will tell us, that according to the *Scripture*, all things were made for our *Sake*, because they are of some use to us. And therefore say, that the *Sun* was *Created* to give us *Light*; that the *Soul* of *Man* was made by *God*, to *Contem-plate* him; yea, that the whole *Universe* was *Created* for *Mans Sake*, seeing that all *Creatures*, are some way or other serviceable to him: And that *Consequently Gods ends* may be known by us, as well as any other *Causes*.

VI. To this may be answered, *First*, That true indeed it is, that the six days of the *Creation* are so described in *Genesis*, as that *Man* seems to be the chief end of them: But it may be said, that this *History* of *Genesis*, was penn'd for *Mans Sake*, and that therefore the *Holy Spirit* was pleased chiefly to set down those particulars which have reference to *Man*.

VII. I answer *Secondly*, That it doth not appear at all, that all things were *Created* for the *Sake* of *Man*. For how do we know, *what* and *how*

many things, *God* hath made besides this *Earth* which we inhabit, in the *Stars* and elsewhere? How do we know, but that there may be other *Creatures*, specifically distinct from any of those which we see, other *Animals*, other *Men*, or at least *Creatures* *analogous* to *Men*, in some other places? These things are unknown to us poor *Mortals*, because the *Divine ends* and *Counsels* are hid from us. When it is said therefore, that all things are *Created* for *Mans sake*, we are not so to understand this, as if they had no other use, save what they render to *Mankind*; but only this, that *Man* can and must exercise his *Wit* and *Under-* *standing* about them. Now it is a quite different thing to say, that *Man* was *Created*, that he might *Celebrate* and *praise God* for the excellence of his *Works*; and to assert that all these things were *Created* for *Mans sake* alone. For in the former, *Mans Duty* is intimated, but in the latter, the end and aim of the *Creator* in making the *World* is determined.

Besides, it is an absurd thing to imagin, the *Sun* to have been *Created* for no other end, save only to enlighten us: And that the *Stars* and *Plantes* were ranged in their several *Vortices*, only to assist and pleasure us; since we are the very least part of the *Earth*, and the very *Earth* it self (in respect of the *Heavens*) is no more than a small *Grain* of *Sand*, compared with a *Mountain*. Wherefore let us take heed of entertaining such presumptuous *Thoughts* of our selves, as if all things were made for our use, profit and advantage only; when there may be an infinite number of *Creatures*, that by many degrees exceed us, whose Nature and Excellence is altogether hid from us. Have not we much more reason to have such *thoughts* as these, than to entertain those other presumptions, when we consider the immense *Power* and *Wisdom* of our *Infinite Creator*?

IX. Some, pretending Zeal for the Honour of *God*, tell us, that his own *Glory* was the end and aim he proposed to himself, in the *Creation* of this *Universe*; as if *Gods* aim in the Production of this *World*, had been only to display his *Magnificence*, and to exalt his own *Glory*. But who can believe this? Shall we say, that *God* could not have provided for his own *Glory*, by other things different from these? Would his Honour have been ever the less, if he had *Created* another *World*? You must then own, that his *Glory* was not the sole motive he proposed to himself in creating of the *World*. Moreover, how can it be said, that *Glory* was the *Creators end*, seeing it is a thing extraneous to him, and which doth not at all belong to his *Essence*? For *God* can never be said to be determin'd in his *Actions*, by any thing that is without him, neither can any thing that is without him, be a motive to him.

VII. It seems a great piece of Rashness to assert that all things were created for Mans sake.

IX. The Glory of God was not the Reason why the World was created.

IX. The Glory of God was not the Reason why the World was created.

IX. The Glory of God was not the Reason why the World was created.

THE FIFTH PART OF THE INSTITUTION OF PHILOSOPHY. SPECIAL Natural Philosophy, CONCERNING THE WORLD AND HEAVEN.

CHAP. I.

Of the Unity and Perfection of the World.

HAVING examin'd those things that belong to GENERAL PHYSICKS, and thereby consider'd a Body or Matter in General; that is, its Nature, Principles, General Affections and Differences; we proceed now to SPECIAL PHYSICKS, or that Part of Natural Philosophy which takes a view of Matter, as distinguish'd into Species, and lays open their several Species, Properties, Distinctions, and Mutations, in a more particular manner.

II. Now the Species of Bodies may be consider'd after a twofold manner, viz. either Jointly or Separately; or, as others express it, Collectively or Distributively. The Species of Bodies are Collectively consider'd, when they are view'd all together, as the Parts that constitute one Whole or Entire Being. Distributively, when the chiefest Species of Bodies that compose the World, are in a convenient Order particularly examined.

III. The whole which contains all the Species of Bodies, is called the World; and is the Comprehension of all Natural Bodies Created of GOD, and for GOD, by the most free Motion of his Will

most beautifully Adorned, and most wisely Governed, and powerfully Preserved. And is thus defin'd by ARISTOTLE; *The Structure of Heaven and Earth, and of the several Natures comprehended in them.* Lib. de Mund. Cap. 2.

For the WORLD comprehends all and every thing that can fall under our Thought. Whatsoever Rhetorick commends, or Philosophy admires, is a part of it. And therefore the Ancients have told us, That the World consists not only of Animals and Men, but of Gods also; and that accordingly, the World is a Kingdom or Commonwealth, compos'd of the Gods, Men, and Animals: Which Saying of theirs is true enough, save only in that it imparts the Name of God to many, which is due to none but One alone.

The WORLD is but One only, neither can a Plurality of Worlds be conceived without a Contradiction; for there can be no more than one Universal comprehension of Bodies, seeing that many Worlds cannot be conceived without Distance, neither can Distance be without Extension, nor that without a Body, which mediating Body would then joyn both Worlds together; for the conjunction of the Parts of the World consists in nothing else but this, that all the Bodies in it touch one another. But to imagin two Worlds separated by a Vacuum or Imaginary Space, that is,

two

I. What is meant by Special Physicks.

II. The Species of Bodies may be considered two ways.

III. The Definition of the World.

IV. The World contains all things.

V. There is but one World, and no more.

The Reverend
of Chetwood in Buck-
descended from the
of Wauhull alias Wood-
Arch-Deacon
This Plate is humbly Dedicated

Knightley Chetwood
ingham Shire, Lineally
most antient Barons
hull, in Bedford Shire.
of York &c.
by Richard Blome.

two Bodies distanced from each other by Nothing, is meer Folly; because to this distance by Nothing would belong *Extension*, *Divisibility*, and *Mensurability*; and it might be either nearer or farther off.

VI.
Plurality
of Worlds
implies a
Contradi-
ction; for
as sham
ed blun-
der.

However, if any one should question, whether there may not be another *World* distinct from this. My Answer in short is, that they who hold a Plurality of *Worlds* not to imply a Contradiction, say, that supposing there were a *World* distinct from this we live in, it might be placed in that Space which we imagine to be beyond the utmost *Heavenly Sphere*; but it is impossible that any Bodies should be there; seeing it is supposed to be *Nothing*, or something *Imaginary* only, and which consequently can have neither *Parts*, nor *Effects*, and therefore cannot place any thing. For *Place* being nothing else, according to *Aristotle*, but the *Surface of the ambient Body*, how shall we find a place there, where no Bodies, nor *Surfaces* are to be found?

VII.
Many
Worlds
cannot be
united to-
gether.

Moreover, if beyond the highest *Heaven*, there should be another *World* like to this, either they would touch one another, or be separate. If we suppose them separate, there must be some *Medium* that may wholly surround them both, and so neither of these *Worlds* would be utmost, as having still something beyond them; and if they touched one another, being *Round Bodies*, there must be a *Vacuum* left between those parts, that did not touch; but we have proved a *Vacuum* to be an Impossibility in *Nature*, in our *General Physiology*. Besides, the Space which we imagine to be betwixt these two *Worlds*, is not a meer *Nothing*, but a *Body*, since nothing but a *Body* can make a *Distance* betwixt two Bodies: For we cannot conceive one thing to be distant from another, without some real *Medium* that separates them, which seeing it can be nothing else but a *Body*, it will joyn both *Worlds* together, and so instead of separating these two *Worlds*, it will unite and make but one of them.

VIII.
Whatsoever
we imagine
to be Ex-
tended, is
a Body.

But to put an end to this Dispute, we say that this *World* hath no Bounds of its *Magnitude*. For seeing every Space is something extended, and that no *Extension* can be without a *Body*, we conclude that nothing can be conceived by us beyond the *Heavens*, but what must be Real; and consequently that there can be no other *World* besides this. And yet it cannot be infer'd hence, that the *World* is *Infinite*; but only that it is *Indefinitely Extended*, because we cannot conceive so great an *Extension* in the *World*, but we may still imagine Greater, forasmuch as all imaginable Spaces are fill'd with *Matter*.

IX.
The World
is not Infi-
nite, but
Indefinitely
extended.

You'll say, If the *World* be *Indefinite*, that is, if we can imagine no Bounds or Ends of its *Extension*, it must be *Infinite*, because *Infinite* is nothing else, but that which hath no End.

X.
The first
Answer.

I answer, First, All grant that there are *Indefinite Parts* in every *Body*, so that it is impossible to come to the last of them; and yet no body ever asserted, that therefore a *Body* was *Infinite*. So tho' we admit an *Extension* in the *World*, the end whereof we cannot imagine, yet is not the *World* therefore to be reputed *Infinite*. For I do not see how that which hath *Finite Parts* can be accounted *Infinite*; nor how any *Mass* or *Bulk*, which *GOD* can take something away

from when he pleaseth, can be called *Interminate*.

I answer, Secondly, that there is a great difference betwixt that which is *Infinite*, and a thing *Indefinite*; for we cannot assert any thing to be *Infinite*, except we have a Reason whereby we can demonstrate it is so: Whereas to assert any thing to be *Indefinite*, it is sufficient, if we have no Argument which proves it to be *Finite*. Which cannot be proved of the *World*; for it cannot be understood, that the *Matter* of which the *World* is made should have any Bounds, seeing that whatsoever we imagine beyond the *Heavens*, we still conceive it as an extended Space, which hath Length, Breadth and Depth, which constitute a *Body*. Of which we shall speak more fully in the Third Chapter.

We cannot doubt of the Perfection of the *World*, if we consider either the *Author* of it, who is *Infinite*, *All-wise*, *All-powerful*, &c. or the *Harmony* of the *Parts* of the *World*, the *Distinction* of *Natures*, and *Difference* of *Bodies* that are in it; because we meet with nothing in it which is not Compleat and Perfect.

And tho' the *World* doth not consist of things that are all best in their kind; because all particular things that are in the *World*, if considered in themselves, cannot be said to be *Perfect*, but only with reference to the whole *World*, whose parts they are. For all things that concur to the constituting of any thing, must not be of one and the same Order. What would become of a Republick, if all the *Members* of it were *Senators*? What would the *Body* of *Man* be, if it were made of nothing but *Eyes*? What would *Musick* be without *Discords*? So likewise the *Beauty* of the *World* consists in the *Diversity* of *Kinds* that are in it; and things *Imperfect*, as well as *Perfect*, contribute to its orderly and most excellent Constitution.

Wherefore this admirable Structure of the *World* would want much of its *Beauty*, without that *Vicissitude* and *Inconstancy* which we find in it. Hence it is that all things made by *GOD* are subject to *Corruption*, neither is any *Body* so firm, which in continuance of Time is not changed. Thus it hath been observed of late, that *Worms* are generated not only in *Stone*, but also in *Glass*; so that we may well conclude, that there are no *Bodies* in the *World* that are altogether exempt from *Corruption*.

But you'll say, Why are there so many Excrements of the *Earth*, *Air*, &c. in the *World*? Why were *Worms*, *Flies*, *Serpents*, &c. Created? since these frequently are mischievous; and other *Creatures* again perish, without having been of any use at all? I answer, that none of these things are *Superfluous* in the *World*, seeing that they are Instances of the *Power* of *GOD*, and if *Men's* Industry be not wanting, may be employ'd to many good uses. The very *Poison* of *Venemous Creatures*, by preparation and due exhibition, become great *Antidotes*; neither is there any thing so deformed in the *World*, which doth not add to its lustre and beauty, as *Shadows* set off a *Picture*.

XI.
The second
Answer.

XII.
The World
is Perfect.

XIII.
The Imper-
fection of
Parts, takes
not away
the Perfe-
ction of the
whole.

XIV.
The Har-
mony of
the World
consists in
it Variety.

XV.
It is no
Argument
against the
Perfection
of the
World, that
some hurt-
ful things
are found
in it.

The Creation of the World proved by Natural Reason.

THE Authority of *ARISTOTLE* hath of a long time been so prevalent in the World, that hath been looked upon (and is so still by some) as a great Error to depart from his Opinions: Which is more particularly evident in the matter before us; For he supposed the World to have been from Eternity, and could not conceive how it could be produced, seeing that between *Entity* and *Non-Entity* there was an *Infinite Distance*. Some of his Followers have asserted the same thing, grounding their Opinion on their Masters Foundation; that out of nothing, nothing can be made, and that it was a plain contradiction, to suppose any thing to be made, but from *Præexistent matter*. Wherefore to overthrow this Opinion, so derogatory to the Glory of the Creator, I shall prove, that *Creation* is *Naturally Demonstrable*, and that it may easily be proved, that all things proceeded from *God*.

By *Creation* we understand, that *Action* where- by *God* immediately produceth any thing: And that he hath in this manner produced all *Substances*. I prove thus.

There is nothing in the *Universe*, whereof we may not enquire whence it *Exists*; or what is the cause of its *Nature*, and the efficient of its *Existence*. And this may not only be enquired concerning things *Created*, but likewise of *God* himself; who tho' he be *Independent*, *Infinite* and *Omnipotent*, yet it may be said, that his *Immensity* is the cause or *formal Reason*, why he needs no cause for his *Existence*. But forasmuch, as nothing like this is found in all other things, but rather the greatest Limitation and Infirmary, we must conclude, that they never proceeded from themselves, but from an outward Principle, and that they derive their whole *Essence* and *Existence* from another. For it is most evident, that nothing (if I may speak so amongst *Philosophers*) preceded their *Natures*, and that they came to be, by the Goodwill of the *Creator*, which is to be *Created*, and to proceed without dependence upon any other Cause whatsoever.

The same may be proved from the *Preservation* of all things: For it cannot be conceived, how a thing that cannot preserve it self, should proceed from it self; for if a thing be supposed sufficient to afford it self a *Being*, we cannot but conclude, that it would bestow upon it self, all those *Perfections* it hath any *Idea* of; and seeing *Conservation* is one of these, neither would he deny it self this. For it is the sense of *Philosophers*, that *Conservation* differs only notionally from *Creation*; and that it is the work of the same *Agent*, to produce an effect at first, and to preserve it by a continual influx. Now it is evident by Experience, that no *Created things* can preserve themselves, therefore neither can they produce or *Create* themselves.

This will appear more clearly, if we divide *Time*, by separating the several moments of it from each other: For it is evident, that there is no *Union* between them, and that each single part of it, hath no dependance at all upon the rest. For it doth not follow, that because I was the last year,

therefore I shall be the next year; seeing that I may die, in the very moment that I am writing this. Conclude we therefore, that that *Being* cannot produce it self, which cannot preserve it self; seeing that *Conservation* is nothing else, but a kind of continued *Production*, which is only by our Understanding distinct from *Creation*.

All this *Discourse* is very accommodate to our way of conceiving. For if it be true, that that *Exists*, which we understand to be without its Causes; then that also will be possible, which is clearly and distinctly known by us to be such: But we clearly and distinctly perceive, that it is possible for the *World* to have been *Created*; therefore we must conclude, that it was actually *Created*, since nothing is found in the *Universe*, which is not dependent. For if *Independence* did belong to the *Sun*, for Example, or the *Earth*, the *Sun* and the *Earth* would be *God*, because *Independence* cannot be without *Infinity* and *Omnipotence*. Whence it follows, that either *Creation* must be admitted, or we must expose our selves to one of these two Absurdities; either that there is something in the *World*, that had no *Maker*; or that in the subordination of Causes, there may be a procession to *Infinity*, both which are inconsistent with Reason.

It is absurd to admit any thing in *Nature*, which was neither of it self, nor produced by another. For whatsoever the *Mind* of *Man* can conceive, is either of it self, and then it is *God*, since in the Conception of *God* all manner of *Independence* is included: Or is from another; and of that other we must enquire again, whether it be of another, or of nothing; if it be said from another, we must further enquire of that other, until at last we come to that one Principle, which hath brought forth all things.

For we are not to imagin with some *Atheists*, that the *Creatures* are joynd together like *Links* in a *Chain*, which tho' they be all linked together, yet is there no necessity that the *Chain* made by them, should be united to another *Chain*; because the parts of a *Chain* are not produced of themselves; but only keep some order amongst themselves. Now it is not in the least contradictory, that two distinct things should be united together. We know that all things produced, are caused by another, and that therefore it is necessary, that one thing as to its *Existence* should be before another; for the *Effect* is after its *Cause*, as receiving its *Being* from it. And thus of necessity we must at last come to one *Primary Cause*, which produced those effects, or else must proceed to *Infinity*, which is the greatest absurdity in *Philosophy*, seeing that nothing is more evident than that a *Determinate effect*, must come from a *Determinate Cause*: But how can this be, if we can never come to the *First Efficient Cause*, but still a further cause may be assigned, from whence the effect proceeds? Wherefore we must conclude, that there is some *Determinate Cause*, from which all other things flow and are produced.

This *Truth* was owned by the *Antient Philosophers*, who clearly perceived that the *Mind* of *Man* and *Intelligences* in their *Production*, did not depend on any *Præexistent matter*, as being altogether different in their *Nature* from it. Moreover,

This *Truth* was owned by the *Antient Philosophers*, who clearly perceived that the *Mind* of *Man* and *Intelligences* in their *Production*, did not depend on any *Præexistent matter*, as being altogether different in their *Nature* from it. Moreover,

IV. If the World had not been made, it would be God.

IV. If the World had not been made, it would be God.

VII. Things are not so connected as to have no dependence upon the first principle.

XI. The World is not so connected as to have no dependence upon the first principle.

VIII. The Philosophers owned the Creation.

IX.
It implies
a Contra-
diction
that there
are more
Indepen-
dent Beings
than one.

Moreover, who sees not that it implies a contradiction, that there should be more than one Being of and from it self, that is, Infinite, Omnipotent, Immense, &c. For whatsoever Being is of it self, must include all Perfections; and consequently, if all the things we see in the World, were their own Makers, there will be so many Infinite Beings, as we conceive that there are Independent things: Which is contrary to the order of things, and to the Light of Nature. Wherefore ARISTOTLE attributes to his Heaven, Immutability, the highest Perfection, and Divinity it self: As is evident to him that reads his Book, *de Cælo*. cap. 2. & 6. *Ethic.* cap. 7.

X.
Many mat-
ters of
Faith may
be manifest
by natural
Reason.

Neither doth it thwart what hath been said, that the Creation of the World is one of the Articles of our Faith: For Faith is not contradictory to Reason; yea, we may search out many things by Reason, which we embrace with a Firm Faith, from the Divine Revelation.

XI.
Three sorts
of Questions.

And that we may the better distinguish these Points, from those things which are matter of Faith only, we are to observe that there are three general Heads of Questions: Some are such as we first assent to by Faith only, such are the Mysteries of the Trinity and Incarnation. Other Questions are such, which tho' they belong to Faith, yet may be searched out by Reason, as the Unity of God, the Creation of the World, the Existence of God, and the Immortality of the Soul Man. And the last sort of Questions are such, as do not at all belong to Faith, but Human Reason: Such as are about Gold to be made by the Art of Chymistry, the Squaring of a Circle, and such like. As to the first sort of Questions, tho' they exceed the reach of Mans understanding, yet we are to believe them to be most true, because revealed to us by the Holy Ghost: Such points as these are indeed above Reason, tho' not contrary to it. Concerning the middle sort of these Questions, Philosophers may enquire, and shew that they are so far from being contrary to Reason, that they may be found out, cleared, and confirmed by it. As appears in this Question of the Creation of the World, in the handling whereof, I think, I have made it evident that the World could have no other Original but that of Creation.

XII.
Whether
the World
could have
been sooner
Created
than it
was.

Some curious person may enquire, why the World was Created just at such a time, and neither sooner nor later?

I answer in the First place, that before the Creation of the World there was no Time: For seeing Time is the measure of successive Duration, I do not see how possibly it could have any Being, before the Existence of changeable things. And therefore St. Austin Lib. 5. *de Genes ad Litt.* cap. 5. saith, It is in vain to look for Time before the Creation, as if Time could be before the Creature was. For if there was no motion of any Spiritual or Bodily Creature, by means whereof future things might succeed to things that are Past, by the present, there would be no Time at all; nor could the Creature be moved before it was. Wherefore Time rather had its Beginning from the Creature, than the Creature from Time, and both of them from God. Therefore to speak exactly, the World did not begin to be in Time, but had its Beginning with Time: And consequently, they speak very improperly, who say, the World might have been sooner

or later produced, because these expressions denote Parts of Time: Now it is apparent that Time presupposeth the World and the Creatures, and is a concomitant of them.

CHAP. III.

The World is not Circumscribed by any Figure or Bounds.

THOSE who derive all Knowledge from their Senses, cannot conceive that there should be any sensible parts of matter, of which Bodies are framed, only for this Reason because they cannot see, or perceive them by any of their Senses. For they think it to be an absurd thing, that any thing should be represented to the Mind, which comes not in by the Senses.

There are some of these, who after that they have asserted, that all the Bodies in the World consist of three Dimensions, and that none of them can be imagined so small, but that they consist of various Sides and Surfaces, do conclude the World to be of a Round or Spherical Figure, so that all the Lines drawn from its Center to the Circumference are equal. The chief ground of this their assertion is, because a Round Figure is the most perfect of all, and most conservative of the Body to which it belongs: And that the Universe, as being the most noble of all Creatures, must needs have the most excellent and useful Figure. And they defend their Opinion by ARISTOTLES Authority, who saith, that nothing is corrupted but by its contrary; and that seeing the Heavenly Bodies, are Ingenerable, and Incorruptible, it was necessary they should have such a Figure whose motion hath no contrary.

But ARISTOTLES Authority must not be more prevalent with us than Reason; for if a Round Figure were conducive to the everlasting Permanence of things, it would follow, that things of that Figure must be Incorruptible: Yea, it would depend on our Will to make things Incorruptible; since it is in our Power to make Wood, Wax and such like Bodies of a Round Figure. Nay, if this were true, there would be no Bodies in Nature, but what would be Incorruptible, forasmuch as all of them have some kind of Roundness, because a Circular Figure lies hid under their Angles; and therefore a Cubical or Square Body, as to its Spherical Figure would be Incorruptible, whereas its Angles, which cover the said Roundness, would at the same time be Corruptible.

Neither is a Round, more excellent than any other Figure; for seeing that every Figure, especially those that are Regular, have their Beauty, yea, and that those are lookt upon to be more curious, which have most of variety, why should not a Body of 8, 12 or 20 Sides, be more excellent as to its Figure, than a Globe? Or shall we think a Round Figure to be most beautiful because it is most smooth, and most even? If so, why are not all precious Stones rather formed into a Round Figure? And why is not Man, who is the most excellent of all other Creatures, of the same Shape? Wherefore I will conclude with VELLEIUS; I Wonder at those who will have the World to be a Living Creature, Immortal, Happy and of a Round Figure, because PLATO denies that any Figure is more Beautiful than it; whereas in my Mind, that of a

What we
are to un-
derstand
by the
name of
Space.

a Cylinder, or a Square, or a Long Figure, or Pyramid do exceed it.

But if we consider the Nature of a Body or Matter, we shall be convinced, that no Figure can be ascribed to the World: For the essence of a Body consists in Extension, so that whatsoever hath three Dimensions must be a Body. Which being granted, it will follow, that the whole World cannot be terminated by any Figure, because whatsoever we can imagin without the Bounds of that Figure, must be a Body, neither can it otherwise be conceived by us, than as extended in Length Breadth and Depth: For Nature abhors a Vacuum, neither can any space be assigned, which is altogether empty, that is, devoid of any Corporeal Substance.

Wherefore we cannot represent the World so great to us, but that we may still conceive it greater; for tho' we may conceive that probably there are many Bodies like the Earth, that may be inhabited by diverse Animals, yet is it impossible for us to conceive many Worlds, forasmuch as that wherein we are, takes up more space than we can imagin.

Some endeavour to prove the World to be bounded, because it consists of divers Parts, whereof some one begins its Magnitude, and some other terminates it; and seeing that all the Parts of Matter are bounded, that which results from them must needs be terminated also; because every thing that is Divisible is Finite.

This Argument, how much soever they may value themselves upon it, is very inconsiderable, and more thwarts their own sentiment, than ours. For no Philosopher ever denied that Matter was Partible, since Divisibility is its property; yet no body ever acknowledged, that by dividing Matter, we can ever come to its last Particle. Wherefore they infer wrongly, that the World is Finite, because it hath Parts; for the inference from hence rather ought to be, that the World is Indefinite, seeing that beyond all the Bounds we can possibly assign it, we still find extended spaces, nor can our Imagination ever reach to any last or utmost limit that might bound it.

This matter will be further cleared, if we consider what Space is, and how it differs from a Body. By the name of Space we understand all that Extension, which we conceive as reaching in Length, Breadth and Depth; so that Space properly speaking is nothing else, but Internal Place, whereby the Magnitude, Figure and Situation of Bodies, amongst other Bodies are determin'd. And Space thus described doth not indeed differ from a Body, but according to our way of conceiving; because we conceive the Extension of Space, as something common and Generical; whereas we consider the Extension of a Body, as something Individual and Singular. As for Example, when a Tower is taken away, we imagin that its extension is also taken away, because we conceive the same as Singular, and belonging only to it, and suppose the Extension of the place, wherein the Tower was contained, to remain the same, tho' another Building be erected in the same place, or some other like Body be placed there. Because here Extension is considered in common, and is lookt upon to be the same, whether of a Building, the Air, or any other Body, so it be but of the same Bigness and Figure, and in the same Relation, of Distance or

Nearness, to those External Bodies which determin that place.

We see then, that it is the same Extension that constitutes the Nature of a Body and Space, and that there is no other difference between these two, but that which there is between a Genus or Species and an Individual, that is, between the Nature of a Man considered in General, and that of Anthony or John. And as we say, that a Whole includes all its Parts, and all the Parts united together, comprehend the Whole: So tho' Space be said to include a Body, and a Body to be placed in a Space, yet cannot a Space and Body on that account be said to be really distinguished, seeing that the World, which comprehends all things, is not conceived really distinct, from all the Parts contained in it.

Forasmuch therefore as we can imagin no end to Extension or Matter, but that beyond it we still conceive further Spaces, we must needs assert this World to be Indefinitely extended, and that it cannot be bounded by any Figure whatsoever. And tho' we will not arrogate so much, as to suppose our Mind to be the measure of Truth; yet we say, that it must be the measure of whatsoever we do affirm or deny. For it is absurd for us to pass our Sentence concerning any thing, whose Nature we know we cannot reach. Wherefore we make no difficulty, to assert the World to be Indefinitely extended, seeing we can conceive no Bounds in it.

CHAP. IV.

The matter of Heavenly and Earthly Bodies, it one and same.

IT hath been a frequent Controversy amongst Philosophers, whether the Matter of Heaven were the same with that of Sublunary things. ARISTOTLE supposing the Heavenly Bodies to be Incorruptible, will have their matter to be distinct from ours; so that, according to him, there are two parts in the World, the one Elementary, the other Cæstial. He makes the matter of Heaven to be Ingenerable and Impassible; whereas the Elementary is subject to changes, capable of all forms, and craving those it wants. For if we may believe him, the Heavens never suffered any change, and continue still in the same state wherein they were Created. Because Generation and corruption are only found amongst contraries; and seeing nothing is contrary to the Heavenly Body, because its motion is such, as to be contrary to none; for one motion, according to him, can only be opposite to another motion; and since motion upwards, is contrary to that which is downwards, it is necessary that Circular motion, which is proper to the Heavens, must have no contrary, and therefore that Body which is so moved must be Incorruptible.

But what if we should grant the Heavenly Bodies to be Ingenerable and Incorruptible, yet would it not follow from thence that they are not subject to any changes, which we may prove by ARISTOTLE'S own Argument. Those things may be generated and corrupted, that have their Contraries; but that which is Ingenerable and Incorruptible, is contrary to that which is Generable and Corruptible; therefore the Cæstial Orbs are Corruptible

X.
Space and
Body are

return'd up-
on him, and
confuted.

ruptible and Generable. But to leave these Reasonings, let us see what may be alledged against ARISTOTLES Opinion. For asmuch as the Modern Astronomers, have more exactly viewed the Stars than the Antients, I question not, but that were ARISTOTLE now alive, and made use of our Telescopes, he would be of their Opinion. For they observe that the Sun is frequently obscured by Spots which obscure its face, and that these at some certain times are so condensed, that the Light of the Sun for some Months together, appears much weaker. Now that these are generated, cannot be denied, since almost every day they change their Form; they are sometimes of a Black colour, at other times they seem to have a Dusky appearance of Light; yea sometimes they are of that loose texture, that they exceed the Sun in Brightness. All which could not be without Generation and Alteration.

III. The changes which happen to the Planets confirm the same thing; for what is more instable than these wandering Stars? The Moon almost every day gives a various Representation of herself. Saturn seldom appears with the same face. How frequently is Jupiter clouded with Spots, which interrupt its Light from coming to us? Venus is continually changing, and if we may give credit to the information of the Telescope, we must assertherto have several Faces; since she does not only change her aspect, but also her Bulk and Figure, as Astronomers tell us it happens in the time of King Ogyges. Moreover, how many Comets and New Stars, do there appear in the Heavens, as the Star in Cassiopea, and others that appeared in the Heavens in 1572 and 1604, above the height of the Planets. All which PHAENOMENA may be sufficient to make the followers of ARISTOTLE to reject this foolish Opinion of their Master, and to acknowledge the Corruptibility of the Heavens.

IV. Neither are we to be moved by what ARISTOTLE tells us, that he never perceived any such thing in the Heavens, where he saith; *This is likewise abundantly confirmed by Sense; seeing that according to the Records of all past time, never any such change hath happened in the whole utmost Heaven, nor in any of its proper parts.* Well, let us be so favourable to ARISTOTLE, as to take this to be true; but can it be inferred from hence, that no further observations could be made for time to come? For we read that HIPPARCHUS, 200 years after ARISTOTLE, found out a new Star, by the motion whereof he began to question, whether this might not happen more frequently, and whether the fixt Stars also might not have a motion of their own. We know likewise that TYCHO BRAHE descried the foresaid Star in Cassiopea in the Region of the fixed Stars, above Saturn.

V. But we may put the Point beyond all Controversy, considering wherein the Essence of a Body doth consist, and by removing from it whatsoever is Extraneous to it. Thus in the first place it appears, that sensible Qualities are no constituents of it, since it can be without them, and loseth nothing when they perish. Air, which is soft to the Touch, doth not change its Nature, when by being shut up in a Bladder, it appears hard. A Bean is of considerable Hardness, as long as it abides whole, but when reduced to Flower, it becomes soft. But the Air and the Bean continues Bodies for all that.

Neither do Figure, or Motion conduce any thing to the constitution of Matter, since the World which is of no Figure at all, or at least cannot be conceived by the Mind of Man, under any Bounds, still continues to have the Nature of a Body. And the Heavens, which are considered as immoveable, do not therefore cease to be material. And the same may be said of Heat and Cold, and other like Qualities, which may be absent from a Body, its Nature continuing whole and entire.

VI. We conclude therefore, that nothing but Extension constitutes the Essence of Matter, since that alone cannot be separated from it, and is Reciprocated with it. For if you take away Extension, the Body is gone, as when you take away the Body, the Extension is no more.

VII. Forasmuch therefore as the Matter of the Heavens in Length, is extended in Length Breadth and Depth, and that no thing but this Extension is included in the Conception of it, we conclude that the matter of Heaven and Earth is one and the same, and consequently that the Matter of the Heavens is as well subject to Corruption and Changes as that of the Earth is.

VIII. You'll say, that the Heavenly Matter is not under the same Forms as Sublunary things are, because it was never known that Heaven was generated of the Air, or that a Star was changed into an Earthly Body.

IX. If by the name of Forms, in the Objection, be understood those Substantial Principles, which have a different Being from the Matter, and together with it constitute a Natural Compound, I say, that such Forms as these are meer Fictions, and useless to the explaining of Natural Effects. For such Forms must be either Material or Immaterial. If Immaterial, of what use can they be to Matter? How can they perfect it, and communicate to it their Essence, since Matter (according to them) is meer Potentiality, which derives all its Existence from these Substantial Forms. For how can that which hath no Parts, constitute the Essence of a Material thing? But if they suppose these Forms to be Material, then must they of necessity be constituted by Extension, and must be subject to the self same Modes of Variation, which all other Bodies are. For it cannot be conceiv'd that a thing should be extended, without being liable to the change of Figure, Motion, Magnitude, Rest and Situation. And forasmuch as Generation is nothing else but a congruous Adaptation of the Insensible or Sensible Parts, according to the foresaid Modifications, we must conclude, that all Matter is subject to Changes, and consequently, the Elementary Matter doth not differ from the Heavenly.

CHAP. V.

What the Form of the World is: Whether it be the Soul, that is, the Spirit of Nature, or the most excellent Disposition of its Parts.

I. There is nothing that hath been more controverted amongst the Ancients than this Question, Whether the World be endued with a Soul, and vivified by an Internal Spirit, diffus'd throughout all its Parts. Pythagoras and Plato have compared the Universe to Man, and maintain'd it to be

VI. The matter of Heaven and Earth consists in Extension.

VII. The matter of the Heavens and of Sublunary things is the same.

VIII. Objection that the matter of Heaven and Earth is not under the same Forms.

IX. There are no Forms but may inform Celestial Bodies, as well as Terrestrial.

VI. The Opinion of Pythagoras and Plato, concerning the Soul of the World.

be furnish'd not only with *Life* and *Sense*, but also with *Understanding*. For they could not conceive, how that which was devoid of *Sense*, should produce *Sensible* things. And therefore as there is in us a *Power* whereby we *live*, are *sensible*, and *move*, they thought that so likewise in the *World* there must be a *Principle*, from whence all its *Operations* flow; which the *Poet* describes thus,

*The whole, an Inward Spirit doth maintain,
And a great Soul infus'd through ev'ry Vein
Th' unweildy Mass doth move.*

II. Tho' *Plato* suppos'd the *Soul* of the *World* to be like that which is in *Animals*; yet he holds it not to be a *simple Substance*, but compounded of two *Parts*; the one purely *Intellectual*, the other more *Impure*, tho' *Pure*, if compared with the *Grossness* of *Bodies*; and this he makes a kind of *Vehicle* of the *Immaterial part*. So that he makes a distinction between the *Mind* and the *Soul*; the *Mind* being a *Substance* void of all *Matter*, which is the *Higher part* of the *Soul* of the *World*; and the *Soul* being nothing else but the most *subtil Ether*, by means whereof the *Mind* is brought and united to the *Body*.

III. Tho' this *Opinion* of *Plato* at first sight appears strange and absurd; yet in a sound *Sense* it may be asserted. For if by the *Soul* of the *World* he meant nothing else but *GOD* himself, who holds together the dispersed *Parts* of the *World*, animating, governing and cherishing them, it contains nothing contrary to *Faith* or *Reason*: Provided always, that *GOD* be understood not to be the *Informing Soul* of the *World*, that is, a *Constitutive part* of it; but an *Assistant form* only, that is, the *Ruler and Governour* of *Nature*. For *GOD* is the *Moderator* of all *Things*, and is present to all *Things*, whether *Intellectual* or *Bodily*, operating in them, and by them, according to that of the *Acts* 17. 28. *In him we live, move, and have our Being.*

IV. But if *Plato's* meaning was, That this *Universe* was endued with a true *Soul*, and accordingly was a *Real Animal*, from whence all other *Animals* are generated, nothing seems more absurd, than to suppose an *Animal* compounded of an infinite sort of other *Animals*, which feeds upon it self, and yet is destitute of *Sight*, *Hearing*, and the other *Senses*. What, are the *Stars* nourished with *terrene Exhalations*? Or is the *Earth* supported by *Emanations* from the *Body* of the *Moon*? Who will believe such stuff as this? If the *Earth* be sensible, what shall we say of those hard-Hearted *Husbandmen*, which do cut and wound it with their *Plough-shares*? Besides, if we grant the *Earth* to be *Animate*, must not *Stones*, *Iron* and *Water* be so likewise; yea, all other things of the *World*? But you'll say, *Living Creatures* are generated out of the *World*. What then? Must I thence conclude that the *World* is an *Animal*? Why may not I as well conclude the *World* to be all *Stony*, because *Stones* are generated out of it? Or of *Iron*, because its *Bowels* produce *Iron*? Yea, why may I not with equal ground conclude the *World* to be a *Fidler*, or a *Mathematician*, because such are born in it? For tho' whatsoever hath its *Original* in the *World*, doth derive the same from something that is in the *World*; yet not therefore

from the *Soul* of the *World*, that is diffused throughout it, seeing that the *World* contains all manner of things, whether *Animate* or *Inanimate*.

But to urge this with more *Philosophical Arguments*, I say, that upon this Supposition of a *Soul* being diffus'd throughout the whole *World*, it will follow that there can be no *Passion* of *Joy* or *Sorrow* in the *World*, but what all *Men* must be sensible of, and that no *Body* can wound or strike another, without feeling the same himself. For if one *Sensitive* and *Rational Soul* governs and animates the *World*, there must accordingly be but one *Animadversion*, that is, one part of it must perceive whatsoever the other parts do. But we experience the contrary to all this, and therefore must conclude, that there is no such common *Soul* in the *World*.

For otherwise we should not only apprehend things offer'd to our *Mind*, but we should also remember those things, which were never committed to our *Memory*: For seeing that this *Universal Soul* contains all things, and is diffus'd through all, nothing of all the things that are acted any where, could be hid from it; and therefore since by it we perceive *Objects*, and remember them, it must necessarily follow that the *Mind* must behold those things as present, which it never enquir'd after; that is, it must remember those things, which it never perceived.

Moreover, if we suppose the *World* to be whirl'd about its *Axis* in 24 Hours time, it will follow, that whatsoever I set about when the *Earth* is in the Beginning of *Aries*, I shall remember to have done the same when the *Earth* is in the Beginning of *Libra*; tho' that Portion of the *Soul* of the *World*, which informs my *Body* at that time, be then as far from me, as the *Earth* is from the *Sun*. Which *Arguments* sufficiently prove, that there cannot be a *Soul* common to all *Men*.

Doctor *More*, tho' he doth not defend *Plato's* Opinion concerning the *Soul* of the *World*, and thinks it absurd, that a *Substance* endued with *Sense* and *Reason* should be mingled with all the *Parts* of the *World*; yet he admits of a *Spirit* of *Nature*, which penetrates all the *Matter* whereof the *World* consists, and exerts its *Power* in it; which *Spirit* he describes to be (in his *Third Book* of the *Immortality of the Soul*) an *Incorporeal Substance*, but destitute of *Sense* and *Animadversion*, penetrating the whole *Matter* of the *Universe*, and exercising a *Plastick* virtue in the same, according to the various disposition of the *Parts* in which it operates, directing the *Parts* of *Matter*, and their *Motions*, and discovering those *Phaenomena* in the *World*, which cannot be resolv'd into meer *Mechanical Causes*.

The *Arguments* that persuaded the *Doctor* to admit this *Spirit* of the *World*, were the *Trembling* of an *Unison String*; *Sympathetick Cures*; the *Sympathy* there is between *Heavenly* and *Earthly Bodies*; *Monstrous Birds*; the *Magnetick Attraction* of *Iron*; and lastly, the *Spherical Figure* of the *Sun*. For he could not apprehend how the *Unison Strings* of different *Instruments* do all of them shake; if *One* only be touch'd, without the assistance of this *Spirit* of the *World*. How by the *Weapon-Salve* a *Wound* can be Cured at a great

V. Supposing one common Soul of the World, all Men would feel the same thing.

VI. And would remember things they never had perceived.

VII. Yea, and would remember those things as done in one Part of the World, which were done in another.

VIII. Henry More's Opinion of the Spirit of Nature.

IX. Experiments to prove the Spirit of Nature.

great distance. How the *Heavenly Bodies*, which are assumed by *Magicians* and *Witches*, do communicate their Affections to *Earthly things*; and how it comes to pass, that the same things that hurt those, do mischief to these also. How *Monstrous Birds* come to be generated in a *Human Womb*. How it comes to pass that *Iron* is attracted by the *Leadstone*, and of it self, without any impelling Cause is carried towards it. How the *Sun* attain'd its *Round Figure*, except this *Spirit of Nature* be admitted, permeating all the *Matter* of the *World*, into which all these *Phænomena* may be resolved.

X. But I see no necessity of having recourse to a *Spirit of the World* for the explaining these *Phænomena*, since it may better be done by *Mechanical Principles*. For, as to the *First*, the *Trembling* of an *Unison String*, upon the striking of another, whilst all the other Strings remain without any Motion; this is caused by the vibration of the *String* struck, which moving the *Air*, the *Air* reacheth the *String* that's wound up to the same pitch, and makes it tremble; the *Trembling Motion* being easily communicated to a *Body* disposed for such a *Trembling*; and therefore no wonder if it give forth the very same *Sound*. Whereas if the *Trembling Air* rusheth against a *String* that is differently wound up, by giving several hits against it, it hinders it from reverberating; so that it is impossible for it to sound as the other doth. Yet we must not imagine, that only those *Strings* which are tun'd alike do shake, since they do all, or most of them shake; tho' those only do sound, which are in *Unison* or *Diapason*, or some other Concord with the *String* struck.

XI. As to the *Cure of Wounds* by the *Sympathetick Ointment*, or the *Powder of Calcined Vitriol*, and that at a great distance; this is a thing which may very well be question'd. For what is there in *Vitriol* to perform this, save only an *Adstringent* virtue, whereby it is proper to stop *Blood*, and to bring it to a *Scar*? But by what means shall the outflowing *Particles* thereof be guided to the *Wound*, since they only exert themselves to a very small distance? Whence the *Doctor* concludes, they are directed to the *Wound* by this *Spirit of Nature*. But forasmuch as this *Spirit* is diffus'd throughout all the *World*, and indifferently present to all *Wounds*, why doth it rather heal that whence the *Blood* came, than all the rest, since it is destitute of *Sense* and *Animadversion*, and is no more present to that *Wound*, which it is supposed to *Cure*, than to any other? Wherefore when a *Wound* at a great distance happens to be Cur'd this way, the *Cure* is not to be ascribed to the *Powder* or *Weapon-Salve*, which is apply'd to the *Instrument* that made the *wound*; but it seems to happen, because the *wound* is kept clean and wash'd with *Urine*; as is prescrib'd in this case: For *Salt of Urine* is very deterfive and adstringent, and therefore readily closeth the *Mouths* of the *Veins*, consolidates the *Parts*, and skins them over.

XII. As to that particular of *Mens Souls* sometimes quitting their *Bodies*, and appearing in the shape of a *Cat*, *Dog*, &c. and that whatsoever is inflicted on these assumed *Bodies*, doth redound to the hurt of their true *Earthly Bodies*; this I take to be impossible, and therefore think it in vain to

trouble my self about searching out the Reason of it.

As to those *Monstrous Birds* and *Animals*, that sometimes proceed from the *Wombs* of *Women*, there seems no necessity to put this drudgery upon this *Spirit of Nature*, when it may be more commodiously explicated by a propension in the *Matter* apposite to the *Forming Power*, and the intention of *Nature*. Thus we find that the *Seed of Coleworts* degenerates into *Turneps*; and why may not we as well suppose that the *Parts* of an *Animal* may be perverted, by manifold defects of the *motions* and *humors* of the *Womb*, discomposing and altering the *Seed*. And indeed, what wonder is it for a *Woman* to bring forth a *Monster*, when we see the *Body of Man* familiarly to breed *Lice*, which are dreadful *Monsters* when beheld with a *Microscope*. Seeing therefore that *Lice* and *Worms* are apt to be generated, especially where the *Parts* of the *Body* are ill affected; it will not seem strange that in a depraved state of the *Womb* *Monsters* should be generated. But of *Monstrous Births*, see more in my *History of Nature*.

The Reason of the *Leadstone* drawing *Iron*, shall be treated at large in the *Tenth Chapter of the Sixth Part*. And so likewise the Cause of the *Round Figure* of the *Sun*, and *Fix'd Stars*, will be handled in the *Fourteenth Chapter* of this *Part*; to which I refer the *Reader*, to avoid Repetitions.

Forasmuch therefore as the *World* is not endued with a *Soul*, or any *Spirit of Nature*, there being no need of either of them for explaining any *Natural Phænomena*, we conclude, that the *Form* of the *World* is nothing else, but the fit disposition of all its *Parts*, and their intimate Union. For such is the constitution of the *Parts* of the *World*, that tho' they be different, and at a distance from each other; yet they have a mutual *Relation* and *Reference*, and are joyned together by a *virtue* that penetrates them all. But what *virtue* is this that unites them? I answer, that it is the *Subtil* or *Ethereal Matter*, which permeating all *Bodies* is the cause of this *Union* and *Harmony*, as *LUCRETIVS* seems to hint, *Lib. 5.*

The Fluids are all differently Light,
And therefore reach'd the less or greater height.
Then Liquid Ether did the farthest rear,
And lies on softest Beds of yielding Air.

CHAP. VI.

That GOD, as he is the Efficient and Conserving Cause of Matter, so likewise of Motion.

HAVING thus explain'd the *Nature* of the *World's Matter*, and enquired of the *Soul* that acts it, it remains now that we consider, whether the same quantity of *Matter* always remains in the *World*, or whether it be increased or diminished. Some are so stupid as to imagine, that when *Fire* is extinguish'd, it wholly periseth; not considering that *GOD* is the *Creator* of all things, and that the *Creatures* cannot destroy any thing, which his *Omnipotence* hath produced. For tho' the subtil particles of *Fire*, may by a *Fan*, *Bellows*, or the blast of ones *Breath* be dissipated; yet are not they therefore annihilated, but being separated

XIII.
How Monstrous Birds are framed in the Wombs of Women.

XIV.
Magnetick virtue in the Leadstone, elsewhere handled at large.

XV.
The Form of the World consists in the most excellent Constitution of its parts.

Nothing in the World is annihilated.

rated exist in another manner than they did before. For as *Division* doth not make *Matter*, so neither can it destroy it: Wherefore, *Matter* divided loseth nothing of its *extension*, but only ceaseth to be such a *Body*, and becomes changed into another. It is a great mistake to suppose, that those things which cease to affect our *Senses*, are altogether destroyed and annihilated.

II.
Matter is
neither
subject to
Generation,
nor Cor-
ruption.

Matter, according to the Opinion of all *Philosophers*, is neither subject to *Generation*, nor *Corruption*: Wherefore, we must conclude, that there is always the same quantity of it. For indeed how can any new *Matter* enter, seeing there is no *Vacuum*, and that the penetration of *Bodies* implies a *Contradiction*? For if any one part of the *Eyes* suppose, should be taken away or annihilated (as they fancy of the *Fire*, when it goes out) it is certain a *Space* must be left in the room of it, which forasmuch as it hath *length*, *breadth* and *depth*, we must say that another *Body* supplies the place of it. For it becomes the *Infinite Power* of *GOD*, to act in the most constant and unchangeable manner, by preserving that which he hath produced without increase or diminution.

III.
How New
Bodies are
brought
forth in
the World.

But you'll say, That we daily see new *Parts* of *Matter* appearing, which were never before: Thus in *Spring* time many *Herbs* and *Flowers* shoot forth from the *Earth*; and in *Autumn*, the *Trees* are laden with *Fruits*, which did not exist before. Wherefore we may conclude, that the *Substance* of *Matter* is increased.

This Difficulty may be easily solved, by distinguishing between the *First* and *Second Matter*. By the *First Matter* is understood a *Body* in its general Notion, as it includes three *Dimensions*. By the *Second Matter* is meant a *Body*, which besides *Extension*, is endued with *Figure* and other *Modifications*, by which it comes to resort under one or other of the *General Heads* of things. Wherefore a *Body* in this sense is not to be called *Simple Matter*, but something compounded of an *Extended Substance*, and one or more *Modifications*. Thus a *Tulip*, for Example, besides *Extension*, implies such a conformity of *Leaves*, which at different *Seasons* rise and perish. And this *Second Matter* admits some kind of *Latitude*, and may be multiplied or diminished. But the *First Matter* is *Indivisible*, seeing that all *Bodies* agree in *Extension*; the *Soft* and *Insensible*, as well as the *Hard* and *Sensible*. And such *Matter* as this, is neither subject to *Generation* or *Corruption*, and consequently can neither increase or be diminished, being only capable of admitting different *Modifications*, and of assuming divers *Forms*.

IV.
GOD is the
Cause of
the Motion
that is in
the World.

And the same is the case with *Motion*, forasmuch as all things proceeding from *GOD*, depend on him in a peculiar manner, and have nothing of *Truth* or *Goodness*, but what they have received of him: And that *Independency* is the necessary *Attribute* of a most *Perfect Being*, as *Dependency*, as to *Being* and *Conservation* is the *Attribute* of all *Creatures*. For who can believe that the *Motion* of the *Stars* about their several *Centers*, the *Course* of *Rivers*, the daily *Ebbing* and *Flowing* of the *Sea*, and the *Earths* being poised in the *Liquid Air*, are caused and continued by *Chance*? It implies a *Contradiction* to suppose these *Regular Effects* to be produced by any *Power*, besides that of a most *Perfect Being*, who not only created *Matter*, but

also imparted *Motion* and *Rest* unto it. And since the *Conservation* of any thing is a continued *Creation*, we must conclude, that *GOD* is the *Preserver* of that *Motion*, which at the *Beginning* he imparted to the *World*.

So that as *GOD* preserves the same *Quantity* of *Matter* which he created, so likewise of *Motion*, and that without increase or decrease; which is a remarkable *Proof* of *GOD's Wisdom* and *Unchangeableness*. And as for *Matter*, as it could not move it self at first; so it being once put in *motion*, it never ceaseth from it, but continues in the *state* wherein it is put. So that if the *Motion* that is in the *World* should either be diminished, or cease altogether, this must be from the *Divine Will* appointing it so; but no such *Will* of *GOD* appearing, it is certain the same *Quantity* of *Motion* must still continue in the *World*.

When I say, that the same *Quantity* of *Motion* is preserved in the *Universe*; this is not so to be understood, as if all *Bodies* that were first put into *motion*, continue in the same *motion*; and that those that were left at *Rest*, do persevere in the same; but that the same *measure* of *Motion* is preserved in the whole *Universe*, tho' it may be varied and altered in the particular *Parts* of it, with respect to the diverse *Bodies*, on which it exerciseth its force. Much in the same manner, as we say, that in a certain *Kingdom* there is such a determinate *quantity* of *Money*, tho' some *Men* have more of it, and others less, and tho' it be in a continual *Relation* from one to another. So likewise we must conceive, that the same *quantity* of *Motion* is found in the *Universe*, tho' the same be variously possessed by the particular *Parts* of it.

GOD alone can be the *Cause* of this so constant *Motion* in the *Universe*. For if we consider *Motion*, we find nothing by which it should be increased or diminished, for having not produced it self, neither can it increase or destroy it self; nor can the thing moved, or matter, conduce any thing this way, because it is merely *Passive*, and consists only in *Extension*. Wherefore, we must conclude *GOD* to be the *Total* and *Universal Principle* of *Motion*; who at the first instant of the *Creation* of *Matter*, put *Motion* into it, and maintains the same by the same *Action* wherewith he preserves the *Matter* it self; that is, he makes use of the same moving *Force*, without increase or decrease, which removes from one *Body* to another, according as *GOD* applies the same to divers parts of the *World*. For it might seem to be an *Argument* of *Inconstancy* in *GOD*, if he did not maintain the same *quantity* of *Motion* in the *World*, as well as of *Matter*, and this by one and the same *Course*. So that the *Force* whereby *Matter* is moved, is nothing but *GOD* himself, who being most *Wise* and most *Powerful*, acts in the most stable manner; and therefore on his part, this *virtue* can neither increase or be diminished, but ever continues the same, tho' in particular *Subjects* it may be various.

But you'll say, *GOD* is a *Free Agent*, and that Things that are done in the *Universe* proceed from his *Will*. For who knows not, that the *Number* of *Men* depends on his good *Pleasure*, who produceth and preserves more or less of them, as he pleaseth? So that there seems no reason, but that there may be an unequal *measure* of *Motion*

VIII.
An Obje-
ction taken
from GOD's
free Action.

in

IX.
The First
Answer.

in the *World*, seeing that according to the *Free Will* of the *Creatour*, it may be increased or diminished. To which I Answer, *First*, That those *Things* which depend on the alone good Pleasure of *GOD*, cannot be known but by *Divine Revelation*; wherefore the Consideration thereof does not belong to *Natural Philosophy*, wherein nothing is to be admitted, but what may be discovered by *Reason*.

X.
The Second
Answer.

In the *Second* place I Answer, That as *GOD* acts freely, so likewise he acts constantly, and immutably preserves whatsoever he hath once produced. So that we are not only to consider the *Liberty* of *GOD*, but the same in conjunction with his other *Attributes* of *Wisdom*, *Unchangableness*, &c. which all together do constitute his one *Eternal* and *Permanent Nature*. And as his *Liberty* appears in the vast Variety of the *Things* he hath made, so his *Unchangableness* is demonstrated by his conserving the same *Quantity* of *Motion* and *Rest* in the *Universe*. For *Conservation* being a continual *Production*, it would seem to argue *Changableness* in *GOD*, if either any new *Motion* should arise, or præexistent *Motion* should perish.

XI.
There can
be no In-
constancy
in Motion,
neither in
respect of
GOD, nor
of the
World.

We acknowledge indeed, that such is *GOD's* absolute *Power* of all *Things*, that he can destroy, lessen, or increase, whatsoever he hath made, according to the pleasure of his *Will*: But as long as such his *Will* is not discover'd to us, we cannot assert any thing concerning it. And seeing that with respect to the *World*, no *Reason* can be given for the increase or decrease of the *Motion* that is in it, we must conclude that the same force which at first put the *Matter* in *Motion*, doth still continue in it.

XII.
Whence so
many Mo-
tions arise
in the
World.

It remains now, that we explain how this *Motion*, or rather *Virtue*, that moves the *Parts* of the *Universe*, does indivisibly continue the same, when so many *New Motions* are seen every day: As when *Men*, and other *Animals*, that rested in the *Night* time, are all in *motion* in the *Day*; and when *Guns* are discharged, it is certain that the great *Concussion* caused thereby, was not before in the *World*; wherefore, it seems there must needs be more *Motion* in the *World* at one time, than at another.

XIII.
A Body
moved,
dashing
against
another,
doth com-
municate
some part
of its mo-
tion unto
it.

But this will be easily answered, if we consider that every *Body* whilst it pusheth on another, doth lose as much of its own motion, as it transfers to that *Body* it pusheth forwards. As appears in *hard Bodies*, which by dashing against any soft matter, transmit all their motion to it, and are reduced to *Rest*. Hence it is, that a *Stone* falling down from on high to the ground, doth not rebound, but lies still, because it communicates all its motion to the *Earth*. And in like manner, when *Men* or other *Animals* are moved, we must not suppose that they produce new *Motions* in the *World*, when the agitation of their *Spirits* is transmitted to their *Members*; because the more motion the *Members* receive, the less the *Spirits* retain.

XIV.
The Con-
cussion of
the Air by
Guns, does
not prove a
greater

Neither can we infer, that the *Quantity* of *Motion* is increased by the *Concussion* of the *Air*, caused by the discharge of *Canon*: For tho' there may be more of that motion which we call *sound*, yet is there no more motion simply taken: For tho' the commotion of the *Air* be at first made

more vehement, because of the narrowness of the *Space*; yet by degrees afterwards it becomes more remis, as it spreads into wider *Intervals*, because the *Air*, having communicated its motion to the *Neighbouring Bodies*, doth lose as much agitation as it imparts to them.

CHAP. VII.

Of the Action of Bodies, and the Communication of Motion.

Forasmuch as the *Matter* of the *Universe* is divided into innumerable *Parts*, and every one of them have their proper *Motions*; it cannot be doubted but that they must frequently run against one another, and by contrary motions be either hindered, retarded, or wholly reduc'd to *Rest*. Hence, according to the variety of their pushing against each other, the manifold *Action* of *Bodies*, and *Communication* of *Motions* ariseth: *First*, When two *Bodies* by *Contrary motions* run against each other: *Secondly*, When the *Body* moved, runs against a *Body* that is at *Rest*: *Thirdly*, When two *Bodies* are moved the same way, but with a different degree of *Swiftness*. For it is impossible that *Bodies* should push against one another, but that some change of *Motion* or *Rest* must follow thereupon.

The *Communication* therefore of *Motion* consists in this, that according to the *Will* of the *First Mover*, the *Body* that doth exceed the *Body* it meets with in the *Force* of moving forward, doth carry the same along with it, and loseth as much of its *Motion*, as the other receiveth: So that the same *Quantity* of *Motion* always continues in the *World*.

Neither must we infer from hence, that upon this Supposition an *Accident* must remove from one *Subject* to another; because the *Body* that is at *Rest*, doth not receive the same *Numerical Portion* of *Motion*, from the *Body* that runs against it: But forasmuch as according to the *Will* of the *First Mover*, a like motion only ariseth in that *Body*, which upon the impulse of another, begins to move (as has been before explain'd, *Part IV. Chap. XV.*) it cannot be said, that in this case an *Accident* removes from one *Subject* into another.

This *Communication* of *Motion* will be the better apprehended, if we suppose the *Bodies* that are moved to be perfectly *Hard*, and so divided from all the rest, that their motion be neither hindered nor promoted by any circumjacent *Bodies*. For except *Bodies* were perfectly *Hard*, they would not be able to act upon one another; and if they were not separate from all others, so as not to be retarded or turned aside by *Ambient Bodies*, the proportion or difference of *Motions* would not be discernible.

In the *Second* place, we are to suppose, that the medium wherein the *Bodies* move, be such as doth neither hinder nor promote the motion of them. For if the way through which they pass be either soft or fluid, it will hinder their motion, turn it aside, or wholly take it away; and so no exact account could be taken, what the *Force* of each *Body* is in acting or resisting.

Thirdly,

Quantity
of Motion.

I.
There is a
manifold
Communi-
cation
of Motion.

II.
Wherein
the Com-
munication
of Motion
doth consist.

III.
In the Com-
munication
of Motion,
an Accident
doth not
move from
one Sub-
ject to
another.

IV.
In order to
the exact
Determina-
tion of the
Action of
Bodies, it
is required
that they
be perfectly
hard.

V.
And that
the Medium
in which
they are
moved, be
no hin-
drance to
their Mo-
tions.

VI.
A Body is
not changed
but from
an Exter-
nal Cause.

Thirdly, We are to suppose, that every Body, forasmuch as it is simple and undivided, doth as much as in it lies, continue in the same state; nor is it ever changed, but by some *External Cause*. These things being thus far settled, we are, *first*, to enquire, what must happen at the meeting of two Bodies? For every one knows by Experience, that Bodies, whether *Moved* or *Resting*, variously change the condition wherein they are, according to the different Nature of the Bodies they meet with. Thus, for Example, a Body moved changeth its state, by meeting a Body that is at *Rest*, otherwise than it would by meeting with a Body in *motion*. It also variously changeth its *motion*, in meeting with a *hard* or *liquid* Body. And the *Rules*, according to which these Changes happen, are properly that which we call in general, the *Laws of Motion*.

VII.
What Di-
rect Motion
is

Lastly, We are to presuppose, that *Direct motion* is the Translation of a Body out of the Neighbourhood of one that is consider'd as *Resting*, into the Neighbourhood of another, by a right line, which is the shortest of all others, and equally stretch'd out between two Points.

VIII.
The First
Rule.

Figure
15.

Suppose we therefore the two Bodies A and E to be equal, and to move directly towards one another with the same *swiftness*; when they come to D, they will both rebound back the contrary way, A towards the Left, and E towards the Right, with the very same *swiftness* wherewith they came to D. For these Bodies being supposed altogether equal, must consequently have equal force of *Moving* and *Resisting*. And seeing that *Motion* is not contrary to *Motion*, there is no cause that can reduce them to *Rest*: Wherefore we must conclude that they must reflect or rebound with the same *swiftness*, their *Motion* continuing whole and entire.

IX.
The Second
Rule.

But if the Body A be somewhat Bigger than E, and both be moved with the same *swiftness*, A towards the Right hand, and E towards the Left, when they meet together in D, E alone will rebound, and afterwards both of them proceed to move, with the same *swiftness* towards the Right. The Reason is, because every Body that hath less Force, to proceed in a right line, than the other hath to resist, loseth the Determination of its *Motion*: And it being supposed that the Body E hath less force to proceed forwards, towards the Left, then A hath to proceed to the Right, it follows that E, must lose its Determination, that is, must rebound; but because A and E, are supposed to move with the same *swiftness*, and this *swiftness* cannot be changed by any *External cause*, therefore it remains in the same state wherein it was before. And accordingly E, will move towards the Right, with the same *swiftness* it had at first; and A retaining the same *swiftness*, without changing its Determination, will move the same way, and follow E, yet without being able to push it forward.

X.
The Third
Rule.

Again, if these two Bodies A, and E, be supposed equal in Bulk, but that A moves somewhat swifter than E, then not only E will rebound backwards, but A will also communicate to E, the one half of its *swiftness*, wherein it exceeds E. That is, if before there had been six degrees of *swiftness* in A, and four only in E, after their meeting, they would both tend to the Right, with five degrees of *swiftness*, and so proceed to move the same way with the same *swiftness*. For seeing that the Body E, hath

less force to resist, than the Body A, against which it pusheth, hath to move it, it is agreeable to Reason, that it should give way and reflect, and suffer something from the Body A, and that so the Body A should immediately follow E. But seeing that A hath more *Swiftness*, it cannot follow E, and proceed the same way with it, without pushing it forward, and imparting so much of its *motion*, which being added to that which was in E before, makes both their *motions* to be equal. So that if A hath six degrees of *Swiftness*, and E but four; let the two degrees whereby A exceeds E, be divided into four Parts, and then let one part be communicated to E: But because thus the *motion* of A is still swifter than that of E, let the second also be communicated. And seeing that upon the Communication of these two Fourths, the *motion* of the Body E, is made as swift as that of the Body A, it will not be able to receive any farther increase from A, and therefore will retain the remaining two Fourths; and so both of them, with the same *swiftness*, that is, with five degrees of *swiftness*, will move towards the Right hand.

But if the Body E be wholly at *Rest*, and somewhat bigger than A, then with whatsoever *swiftness* A may be supposed to move towards E, it will never be able to move it, but will be beaten back by it, still retaining its *motion* entire. For a Body at *Rest* doth more resist a greater degree of *Swiftness* than a less, and that according to the degree of the Excess of the one above the other; and consequently there will always be a greater force in E to resist, than in A to push forwards. For a Body at *Rest*, doth as much as in it lies continue in its *Rest*, and must by some outward force be driven out of its place, before it can tend any way. Wherefore such a Body doth not only, with all its Parts joyn'd together, resist the *motion*; but also proportionably to its bulk, whereby it exceeds other Bodies, it is made more strong to withstand others that oppose it. And therefore the Body E, because of its greater Bulk, hath a greater Force to resist, than A hath to move. By which means it comes to pass, that it is not changed by A, but with the same Force continues in *Rest*, wherewith the whole Body A will be moved, and dash against it.

Now, that a Body at *Rest* doth more withstand a greater degree of *Swiftness*, than a less, and that according to the excess of the one above the other, is demonstrable from the most common Law of Nature; that every thing, forasmuch as it is simple and undivided, continues (as far as in it lies) always in the same state, neither is ever changed but by outward Causes. Now the state of the Body E, is *Rest*, and in the swifter Body A, the state is quite contrary, and that proportionably to the Excess of *swiftness*. For the slower the *motion* of A is, the less contrary is it to the state of the Body E, which is at *Rest*, because slowness of *motion* partakes of the Nature of *Rest*. Wherefore, if A with the greatest degree of *swiftness* be carried towards E, *Resting*, E will also have an absolute power of *Resisting*; and forasmuch as it resists, it will with a greater force of Action, resist the greater force that pusheth it, than a lesser.

If the Body at *Rest* E, be less than A, then tho' A move never so slowly towards E, it will carry it along, and communicate to it such a part of its *motion*,

XI.
The Fourth
Rule.

XII.
A Body
that is at
Rest, doth
more resist
a greater
Swiftness
than a less.

XIII.
The Fifth
Rule.

motion, as that both of them afterwards may move with the same swiftness. As for Example, If A be as big again as E, it will communicate to E the *Third part* of its *motion*, because that one Third part will move E, as swiftly as the Two remaining parts will move A, because it is as big again. And since whatsoever accrues to the one, is the loss of the other, it is necessary that after this meeting A move one Third part slower, than it did at first, that is, in the same time wherein before it run through the distance of *three Foot*, it will only move *two Foot*.

In like manner, if A were *thrice* as big as E, it would communicate the *Fourth part* of its *motion* to it. If it were *four times* bigger, it would impart a *Fifth part* of its *motion*; and so on. But if A should only a Third part exceed E, and consequently should have the Relation to it, not of Two to One, but of Three to Two, then two *fifth parts* of the *motion* will be transferr'd from A to E, and three *Fifths* will still continue in A. If E be one *Fourth* bigger, and have the same Relation to A, as Four to Three, three *Seventh parts* of its *motion* will be communicated to E, and so four *Seventh parts* will remain to A.

This account will be more evident, if we express the foresaid Fractions by whole Numbers: Saying, if A be to B, as 3 to 2, then of the *five* degrees, into which its *motion* may be distinguish'd, two must be communicated, which will have the same proportion to E, as the three remaining to A: And if A be as 4, and E as 3, out of the seven degrees of its *motion*, three must be communicated, which will have the same proportion to E, as the remaining 4 to A. And if A be to E as 5 to 4, of the 9 degrees into which its *motion* may be distinguish'd, 4 will be communicated, and will have the same Proportion to E, which the Five remaining have to A. And thus we may proceed to Infinity; for tho' the excess of *Quantity* in A, above *that* which is consider'd in E, does by this means grow less, yet it will always be something; and since we may always take so many degrees of *motion*, as there are parts considered in the *Body moving and moved*, taken together, we find no Reason why A should move E along with it, seeing the difference is of one Sixth, Seventh, Eighth, or even of a Hundredth or Thousandth part, and so on.

The account will proceed in the same manner, whether you reckon the *Parts of Motion* to be so many, as there are consider'd in the Bulk of both *Bodies*, viz. the *Moving and Moved*, or whether you attribute two, or three, or four *Parts or Degrees*, and so on, of *motion*, to every one of the *Parts of Bodies*; because the same Proportion will continue every where between the *Motion* that is communicated, and that which continues in the *Mover*. Thus we may say, that if A be one Third bigger than E, of the 10 parts into which its *motion* may be distinguish'd, 4 will be transmitted to E, the remaining 6 continuing with A: Or, if we suppose 15 parts of *Motion*, then 6 will be communicated and 9 will remain; if 20, the *Body E* being a Third part less than A, will receive 8 of them, and A will retain the other 12. For all these Numbers, 12 to 8, 9 to 6, 6 to 4, have the same Proportion together which they ought to have, which is 3 to 2; and therefore it is all one

which of them you take, and you may increase them to Infinity. And how slow soever you suppose the *motion* in A to be, it will still in the same proportion act upon E, that is, will always communicate to it only such a *part* of its *motion* as shall bear the same proportion to E, as the remaining part hath to A. And thus, if A be as big again, whether it be swiftly or slowly *moved*, it shall always transfer a Third part of its *motion* upon E; if thrice as big, only a Fourth, and so on.

If the *Body E*, *Resting*, be exactly equal to the *Body A*, *moved towards it*, it will partly be push'd forward by it, and partly beat it back to the opposite side. So that if A should come towards E, with four degrees of Swiftness, it would communicate to E one degree, and with the three remaining parts would rebound to the contrary side.

For seeing that both these *Bodies* are supposed of equal bigness, they must also have the self same Force of *Acting and Resisting*: Now this Force to Resist in E, is not only *Negative*, but *Positive*, or, if you will, *Reactive*; because E so admits the *motion* of the *Agent A*, as to cause some change in it, to wit, by *Reflecting* it, and communicating some part of its own *Rest* unto it. And by this means the *Body E* obtains the half of its effect. But the *Body A*, because of its inequality, transfers a part of its *motion* to E, not the whole; for so it would tend to its own destruction, by losing all its *motion*. Thus if the *Body A* should move towards E with four degrees; in meeting with the *Body E*, it would impart one degree to it, and would rebound back with the three remaining parts. If with eight degrees, it would impart two of them to the *Body E*, and rebound with the other six. If it mov'd forwards with twenty degrees, it would communicate five of them to E, and fly back with the remaining fifteen, and so both would obtain the half of that effect, the whole of which they would have, if either of them were greater or less.

Suppose we now the *Bodies A and E*, to move the same way, E more slowly, and A following it more swiftly, so as at last to overtake and touch it: Suppose we also E to be greater than A, but A to exceed in degrees of swiftness the Greatness of E; in this case A will communicate so much of its *Motion*, as that both of them afterwards shall move with an equal degree of swiftness the same way.

That A must overtake E, appears from the Supposition of its being mov'd more swiftly than E; and that it must act upon it, and push it on along with it self, is also evident, because upon examining the proportion of *Magnitude* and *Swiftness* that is between them, we find that the Excess of *swiftness* is greater in A, than the Excess of *Greatness* in E; and therefore by reason of the inequality of *Action* and *Resistance*, it must follow that A, by communicating some part of its *motion* to E, must push it forwards; and so both of them with the same *swiftness* move the same way.

But if the Excess of *Swiftness* be less in A, than the Excess of *Greatness* in E, it will rebound back, and retain all its *motion*. The Reason is, because that which is the stronger in *Action* and *Resistance*, must needs obtain its effect. Now seeing

The Eighth
Rule.

the Body E, by its Greatness or Bulk, exceeds the swiftness of A, and has more force to *Act* and *Resist*, it must push forwards the Body A, and make it rebound backwards. But forasmuch as every thing inclines to continue in its state, except it be hindered by an outward Cause, and this Cause is found in E, viz. an Excess of *Magnitude*, above the Excess of *Swiftness* in A, which changeth the determination of A, but doth not destroy or diminish the Motion it self, therefore it happens that A, by rebounding, loseth nothing at all of its own motion.

But if the Excess of Bulk be greater in E, than the Excess of *Swiftness* in A; that is, if E be as big again as A, and yet A be not moved with a double degree of *swiftness*; then when A comes to dash against E, it will reflect the contrary way, without communicating any thing of its motion. Lastly, if the Body E doth equally exceed A in Bigness, and that it be as big again, which is just as much as A exceeds E in *swiftness*, and therefore hath a motion, that is, as swift again, it will follow that A must communicate some part of that its swifter motion to E, and with the residue rebound back from it.

C H A P. VIII.

Of the Ptolomaick, Copernican, and Tycho-nick Systems of the World.

I. What a System is, and how many there are.

A System in Natural Philosophy is that, whereby a thing acts after a certain manner, by virtue of its Composition, and those Dispositions which constitute its Nature. Thus we call the System of the World, the Order or Disposition wherein we conceive, that all we see in the World is performed, by supposing it to be compos'd of certain Parts, the Nature and Connexion whereof is such, that thence results whatsoever is, or is done in it. Amongst the Systems of the World, invented by Astronomers, there are Three more famous than the rest, viz. those of Ptolomy, Copernicus, and Tycho Brahe, to which all the rest that have been invented by the Ancients may be referr'd.

II. The Ptolomaick System.

Figure 16.

PTOLOMY placeth the Globe of Earth and Water in the Center of the World, and supposeth it destitute of all motion. Next to the Earth, he placeth the Air mingled with Vapours and Exhalations, which raising it self only a few Miles above the Earth, is called the Atmosphere. Next below the Moon he placeth his Element of Fire; the several Spaces above which he divides into Eleven Spheres, in the first Seven whereof he ranks the Planets: In the first ♀, the Moon; in the second ☿, Mercury; in the third ♀, Venus; in the fourth ☉, the Sun; in the fifth ♂, Mars; in the sixth ♃, Jupiter; in the seventh ♄, Saturn; which he calls Wandering Stars: Not that they wander at Random; but because they are carried with an unequal motion within the Zodiac, so as not to keep the same Distance from one another, if compar'd with the fix'd Stars. In the Eighth Sphere he placeth the Firmament, in which the fix'd Stars are supposed to be fastned.

After these follow two other Spheres, which he calls Crystalline, or the Heavens of Libration and Trepidation; the first Moving from the East to the West, the other from the North to the South.

The Eleventh and highest Sphere he calls the Primum Mobile, or First moved. This Description of the World is by the Common People generally approved and maintain'd; who look upon the Heaven as a Vaulted Roof, equally distant from us, who are as in the Center and suppose all the Stars that appear in it, to be in the said Circumference of the World.

NICOLAUS COPERNICUS, a Physician of Thorn, and Canon of Frassenburg, who flourish'd not much above an hundred years since, introduced another System in Imitation of the Pythagoreans, who attributed a motion to the Earth, and plac'd the Sun as the Scul of the World, in the Center of it; and consequently assigns the same place to the Earth, which Ptolomy allows the Sun, that is, betwixt the Planets Venus and Mars. The Earth, according to Copernicus, hath two motions; the one Diurnal, which in 24 Hours space is performed about its own Axis, from West to East; which Motion makes Days and Nights, as shall be said hereafter. And this Motion performs the same Service, which the Primum mobile doth in the Ptolomaick System, to wit, by effecting that all the Stars seem to move from East to West; much in the same manner as a Ship, which sailing from the Shoar, or towards it, makes the Shoar it self seem, as if it drew near, or withdrew from the Ship. The other Motion of the Earth, is its Annual motion, by which she is carried about the Sun, from the West also to the East, according to the Succession of the Signs of the Zodiac; by which means, the Sun which stands immovable in the Center of the World, doth seem to run through those Signs, tho' indeed it is the Earth only that truly doth so. And whereas the Space that is between Mars and Venus, is large enough for the Moon to be carried round between them, she accordingly performs there two Motions, the one Monthly, wherewith she is whirl'd about the Center of the Earth, and appears in her several Changes; the other Yearly, whereby (together with the Earth) she goes round the Sun.

Wherefore, according to the Copernican System, the Sun is placed in the Center of the World immovable. Tho' this hinders not, but that it may be carried round about its own Axis within the space of 27 days, which that it is, appears by the turning round of its Spots, discovered by the Telescope. Next to the Sun, Mercury is whirl'd about; in the second place, Venus; in the third, the Earth, together with the Moon its Attendant; in the fourth, Mars; in the fifth, Jupiter; and in the last, Saturn. After which follows the Region of the fix'd Stars, so called, not because they are without all motion, but because they do not wander up and down like the Planets, but continue in their own places, and keep the same distance from one another, as will be shewed in the XXth Chapter of this Part.

Besides these two Systems, a Third hath been contrived by TYCHO BRAHE, which partakes of both the foregoing Systems. For as to the Digestion of the Parts of the World, it agrees with the Copernican, save only in this, that it constitutes the Earth to be the Center of the Firmament, and accordingly makes the Moon and Sun to run round it. Thus in explaining the seeming motion of the Heaven, which seems to be performed

III. The System of Copernicus.

Figure 17.

IV. The System of Tycho Brahe.

Figure 18.

in 24 Hours, he follows *Ptolomy*, and supposeth the *Earth* to stand immov'd in the *Center*, and the whole *Heaven* to be carried round it, from *East* to *West*, by the Force of the *Primum Mobile*. But in explaining the Appearances of the *Planets*, he agrees with *Copernicus*; making *Mercury* and *Venus* to be carried round nearest to the *Sun*, as their *Center*; but *Mars*, *Jupiter* and *Saturn* at a farther distance; and in the middle Space placeth the *Earth*, with the *Moon* that is carried round her, in the same time that *Copernicus* assigns to it. The *Tychonick System* has this peculiar to it self, that the *Planets*, which perform their own motions about the *Sun*, are whirl'd about by it, so as that *Mercury* and *Venus*, in their Turnings round about the *Sun*, do never take in the *Earth*, as *Mars*, *Jupiter*, and *Saturn* do. So that as *Gassendus* observes, If instead of the *Sun's* whirling about together with *Mercury* and *Venus*, who exclude the *Earth* from the compass they take, and with *Mars*, *Jupiter* and *Saturn* enclosing it, the *Earth* had been suppos'd to be whirl'd about with the *Moon*, comprehending in its compass *Venus* and *Mercury*, but comprehended within the compass of *Mars*, *Jupiter* and *Saturn*, it would come to the same thing; and *Tycho's System* would appear to be nothing else but the *Copernican* inverted.

V. Having given this brief Description of these three Systems, we are next to examine which of them appears the Truest. For seeing that they all differ, and that the Structure or Disposition of the Parts of the World is but one only, we must reject two of them as false, and choose the third us the truest. And tho' we should suppose nothing of Contradiction to be found in any of these Three, yet ought we to pitch upon that as the best, which appears the most simple, and supposeth least particulars.

VI. Wherefore we cannot admit of the *Ptolomaick System*, as being contrary both to Reason and Experience: To Experience first, with regard to the appearances of *Venus* and *Mercury*, seeing it is evident that these Planets are not always whirl'd about on this side of the *Sun*, as *Ptolomy* supposeth, but sometimes appear above, and sometimes beneath, yea, and sometimes also side-ways to it; so as that sometimes they are nearer to, and at other times they are further from us than the *Sun*. For this Cause *Copernicus* took occasion from the various appearance of *Mars*, to assign motion to the *Earth*. For he perceiving that *Mars*, whilst he is opposite to the *Sun*, appears much greater; and that he grows less, as he nearer approacheth to it, could not attribute this change to any thing better, than to the Circumrotation of the *Earth*: According to which, it was necessary for *Mars* to appear biggest, when the *Earth* moves nearest to him; and least, when the *Earth* leaves him on the other side of the *Sun*.

Secondly, Pursuant to this System, no Reason can be given why *Mars*, *Jupiter* and *Saturn* are always in the lower part of their Epicycles, when they are Retrograde. Whence it is that the *Moon* doth always turn the same part of her Body towards us: Why *Saturn* appears in a various shape to us, sometimes Oval, and at others Round, when beheld through a Prospective.

Thirdly, This Hypothesis doth not explain the

contrary Motions, whereby the Stars at the same time seem to move from East to West, and from West to East.

Fourthly, Neither can the rise of Comets, nor their motions, be solved, as long as we suppose the Heavens to be solid, as he doth.

Fifthly, According to this Hypothesis we cannot give any account, how the Spots about the Sun are generated, and afterwards dissipated; nor how they can perform their Circuits about the Sun.

This System is also contrary to Reason, by allowing the motions of Trepidation and Libration to the Crystalline Heavens. For what is more misbecoming a Philosopher, than for the extricating of a lesser Change, to admit a far greater? For a Body that is carried towards one Point, tho' by an uneven motion, questionless doth not undergo so great a Change, as another, which is also carried towards one Point, and suddenly rebounds to the opposite Point. To this may be added, that it was in vain that the Ancients had recourse to this motion, for the explaining of the Equal progress of the fix'd Stars; since the most exact Astronomers frequently Experience, that what they deduce thence by their Computations, doth not correspond with the Phenomena. Besides, the Motion of the Heavenly Orbs will be swifter than can be competent to such vast Bodies, and more especially to the Brittle Crystalline Spheres; for the utmost Sphere of the World must be whirl'd about in 24 Hours. Moreover, what is more improbable than that the *Primum Mobile* should have the force to carry round with it all the Inferiour Orbs, from East to West; and yet that the *Earth*, which is included in them, should remain unmov'd? When yet, according to *Ptolomy*, the *Earth* is altogether Passive, and is encompass'd with the subtil Matter. These Absurdities are sufficient to make us reject this *Ptolomaick Hypothesis*.

Tho' the *Tychonick Hypothesis* seem more probable than the *Ptolomaick*, forasmuch as it gives an account of the Inequality and Diversity of the Celestial Appearances, yet is it not without its obscurity and defects. For it seems in a manner to disjoyn the whole System of the World, forasmuch as whilst the *Sun* (the Center of Five of the Planets) whirls about the *Earth* in its Annual motion, this his Annual motion is entangled with the proper motions of the several Planets; for the explaining whereof he is fain to make use of a Circle, describ'd from the *Sun's* Center with two Epicycles; whereas the structure of the World, is without doubt very far from any intricacy or confusion, and allows every Planet a sufficient Space to run its Course in.

Besides, this System hath several other Defects for which it is to be rejected, as well as the *Ptolomaick*. For tho' it admits of less Suppositions for explication of the Motion of the Planets, and gives a plausible account of the Appearances of *Venus*; yet it cannot be deny'd, but that it requireth something, which the Mind of Man can hardly assent to, in that it supposeth that Motion, whereby the Mass, consisting of the Heavens and Planets, in Twelve Months time, moves towards all parts of the Firmament. For tho' we should admit, that it had been put into such a motion by the Author of Nature, at the beginning of the Creation; yet withal

VII. This Hypothesis is likewise contrary to Reason.

VIII. The Tychonick System also hath its Errors.

IX. And is to be rejected, as well as the Ptolomaick.

withal we must suppose, that according to the *Laws of Nature*, which GOD himself hath established, the said *Motion*, in success of *Time*, must be diminished, and at last cease altogether; since (according to the same) it must have been communicated to the *Heavenly matter*, which the fore-said *Matter*, to which *BRAHE* assigns this *Motion*, drives from those *Parts* to which it tends.

X. It remains therefore, that we only admit of the *Copernican System*, as being both more plain and simple than the two foregoing, and solving the *Phænomena* of the *Heaven* the best of the three. But forasmuch as *Des Cartes* professeth himself to dissent from *COPERNICUS* and *TYCHO* as to the *Motion* of the *Earth*, which he denies with more *Truth* than *TYCHO*, and with more *curiosity* than *COPERNICUS*, we intend last of all to propound his *Scheme*, as the only true one.

CHAP. IX.

Of the true Systeme of the Universe.

I. **D**ES Cartes supposeth that *Matter* indefinitely extended, and by *motion* imprest upon it, divided into various *Particles*, did run together into several *Vortexes* or Whirl-Pools, whirling about some certain *Points* with a most swift *motion*; that the more subtil *matter* gathered together about the *Center* of these *Vortexes*, constitutes the *fixt Star*; that the *matter* which is a degree bigger, makes the *Heavens*; and that the more solid *Bodies* (such as is the *Earth* and the rest of the *Planets*) hanging poisd in this fluid *matter*, comply with the *motion* of the *Vortex* about the *fixt Star*, and may over and above this, be whirled about their own *Axis*; as we often see that *Bodies*, carried in a fluid *Stream*, are turn'd round by a *motion* of their own, that is, proper to themselves, and not derived from the *Stream* wherein they are carried.

II. Moreover *Des Cartes* divides all the *Vortexes*, that compose this *World* into two *Heavens*. In the first, he supposeth all the *Matter* of *Heaven* in which the *Planets* move, to run round continually in manner of a great *Vortex*, or mass of fluid *Matter* whirling round, in the *Center* whereof is the *Sun*, S, and that those *Parts* that are nearer to the *Sun*, move more swiftly, than those that are more remote, and that all the *Planets* (of whose number also the *Earth* T is,) have their course continually amidst the *Parts* of that *Celestial Matter*.

III. The second *Heaven* comprehends an immense number of other *Vortexes*, which surround this *Vortex* or first *Heaven* A, B, C, which in their *Centers* have the several *fixt Stars*. And because we are uncertain at how great a distance the *fixt Stars* are from us, and cannot conceive them so remote as to contradict the *Phænomena*, we will not content our selves with placing them above *Saturn*, but will take the liberty to conceive them much higher; seeing that it is apparent from the *Celestial motions*, that they are so far distant from us, that *Saturn* compar'd to them, seems to be very near us. *Des Cartes* to illustrate the *Truth* the more about the *motion* of the *Planets*, and especially of the *Comets*, made no difficulty to assign an immense distance between *Saturn* and the *fixt Stars*.

IV. Neither is this in the least contrary to Reason, forasmuch as we know that *Mercury* is above two hundred *Diameters* of the *Earth* distant from the *Sun*; *Venus* above Four hundred; *Mars* Nine hundred or a Thousand; *Jupiter* above Three thousand, and *Saturn* Five or Six thousand. And proportionably we may extend the Space between *Saturn* and the *fixt Stars*, to any distance how vast soever. For tho the *Region* of the *fixt Stars*, be commonly reputed the utmost Bounds, of the *World*, yet its *Figure* cannot be certainly determined by us, seeing we can perceive nothing of its *Internal* nor *External Superficies*.

V. The first of the *Planets* and nearest to the *fixt Stars* is *Saturn*, who sometimes appears as if he had three *Bodies*, sometimes Long or Tall, sometimes Spherical, sometimes Oval, with *Ears* and *Ear-rings*. For tho' *Saturn* like the other *Stars*, be of a Round *Figure*, yet is he surrounded with a broad *Circle* or *Ring*; standing at an equal distance from him; the proportion of the *Semidiameter* of the *Planet*, being to the distance of the *Ring*, as 3 to 5: but the entire *Diameter* of the *Ring*, to that of *Saturn* is about the proportion of 11 to 5. The *Ring* is thin, but broad, and if continued, would pass through the *Center* of *Saturn*. This *Planet* being most remote from the *Sun*, the *Center* of this our *World*, and being moved in a large *Vortex*, is almost 30 years in finishing his *Circuit* in our *Heaven* A B C.

VI. Three *Satellites* or *Guards*, are observed to move about him, the First whereof is distant from the *Center* of *Saturn*, one *Diameter* of the fore-said *Ring*, and performs his *Circuit* about *Saturn* in the Space of 4 days, 12 hours and 27 minutes. He is seen through a *Telescope* of 35 Foot, in his furthest digression from *Saturn*, but is imperceptible when nearer to him. The Second is much more illustrious, and may be descried by any moderate *Telescope*, and is distant from *Saturn* four *Diameters* of the said *Ring*, and whirls round him in the time of 16 days and 23 hours. The Third is distant from him 10 *Diameters* of the *Ring*, and performs his *Circumvolution* in the Space of about 80 days.

VII. The next to *Saturn* is *Jupiter*, who absolves his Course in almost 12 years. He hath four less *Planets*, as so many little *Moons* to be his Companions, to which *GALILÆUS* gave the name of the *Medicean Stars*, because he first discovered them in the Dominions of the Duke of Florence. Their special names are, the *Jovial Saturn*, *Europa*, *Ganymedes*, *Calisto*; whereof the First or remotest wheels about *Jupiter* in 16 days; the Second in 7 Days; the Third in 85 hours, and the Fourth in 42 hours.

VIII. The Third *Planet* *Mars* is carried about a in greater *Vortex* than the *Earth*, and in a less than *Jupiter*; and finisheth his *Revolution* in near two years. In the midst of this *Planet* C A M P A N E L L A by the help of *Prospectives* discovered a Black *Mountain*, higher than the *Mountains* of the *Moon*: From whence, as likewise from the *Spots*, wherewith his *Face* is sprinkled, *CASSINUS* gathered, that *Mars* was whirled about his own *Center* in the Space of 24 hours and 49 minutes. There is also a round *Ring* somewhat resembling a *Rainbow*, but of a Redder Colour, which surrounds the Foot of that *Mountain*.

The

IX. The fourth place is taken up by the *Earth*, which absolvs its Course together with the *Moon*, (which she carries about in her *Vortex*) within the Space of a Natural year. All the Matter that reacheth from the *Earth* to the *Moon*, is called *Elementary Matter*; and because this Matter contains many parts, which are moved more swiftly than the *Rest*, it follows that they must all of them be unequally determined to recede from the *Center* of their *Motion*, and that those which are more swiftly moved, withdrawing themselves with greater force, do by this means thrust the other parts downwards: Which is the cause of *Gravitation*, as hath been said before.

X. Now that the *Earth* is not placed in the *Center* of the *World*, but rather is as far distant from the *Center*, as from the *Sun*, appears from hence; that all the *Planets* are sometimes nearer, and at other times farther from the *Earth*; and that with such a vast difference, that *Venus* when she is farthest from us, is at a six-fold greater distance, than when she is nearest; and *Mars* is eight times farther distant in the one State, than in the other, which could never be, if the *Earth* were the *Center* of the *World*.

XI. The Fifth is *Venus*, who runs her course in 224 days. She is carried below the *Earth*, surrounding the *Sun*, which may be concluded from the changes of her *Figure* and appearance, proceeding from the *Illumination* thereof.

XII. Next to *Venus* is *Mercury*, finishing his Course about the *Sun* in the Space of 80 days, or as others will have it in 87. He very rarely appears, being for the most part obscured by the *Sun's* Rayes. Hence *GALILEUS* conceives, that *Saturn* for his slowness, and *Mercury*, for his almost continual occultation, ought to be accounted the last of the *Planets*. Now forasmuch as *Mercury* doth not appear, but in his farthest *Elongation* from the *Sun*, he is seldom seen *Round* through a *Telescope*; but sometimes as it were cut in two, as the *Moon* in her *Quarters*, sometimes more *Gibbous*, and at other times *hollow*; and being nearest unto the *Horizon*, and obscured by *Vapours*, its *Figure* or *Bulk* can scarcely be discovered.

XIII. In the midst of this great *Vortex* the *Sun* is placed, as in the *Center* of the *World* unmoved, and like a *Prince* seated in his *Royal Throne*, illustrating all the *Bodies* about him, both *Cherishing*, and *Quickning* them with his *Heat*. *TRISMEGISTUS* calls him the *Visible God*, and *SO-PHOCLES* gives him the *Epithet* of *Beholding all things*. But notwithstanding what we have said of his being unmoved, he may whirl about his own *Axis*, in the of Space of 24 days, which *Astronomers* conclude from the most constant *Motion* of its *Spots*.

XIV. Tho' all the *Planets* with regard to their different *Degrees* of *Solidity* be unequally distant from the *Sun*, the *Center* of our *Vortex*, A, B, C; yet is this common to them all, that they perform their *Periodical Motions* after the same manner, viz. from *West* to *East*, or from A, through B, towards C, according to the succession of the *Signs* of the *Zodiack*. Save only that the *Earth* is carried with a threefold *Motion*, and as the chiefest *Star* amongst the *Planets*, hath the *Moon* for her *Attendant*: So that the *Vortex*, which hath the *Earth* for its *Center*, carries the *Moon* about the

Earth in a *Months* Space, the *Earth* it self being whirled about every day, round its own *Axis*. Thus in the same time, that the *Earth* and *Moon* finish their *Common Circle*, or *Great Orb* once, the *Earth* is 665 times whirled about its own *Axis*, and the *Moon* twelve times carried about the *Earth*.

The Common Objection against this Hypothesis is, that the *Horizon* in all parts of the *World*, divides all the great *Circles* into equal *Parts*, so that always one half of the *Equinoctial* is above it, and the other half under it, and consequently always 6 *Signs* of the *Zodiack* above the *Horizon* and as many under it; whence it must follow, that the *Earth* is in the *Center* of the *World*, and not the *Sun*.

To which I answer, that this proves indeed, that the *Earth* is in the midst of all the great *Circles* of the *Sphere*, but not that she is in the *Center* of the *World*, because it is our *Imagination* only, that represents these *Circles* about the *Earth*. Accordingly it would be a false consequence to say, that the *Earth* is in the *Center* of the *World*, because the *Parts* and *Degrees* of the *Earth*, do correspond proportionably to the *Parts* and *Degrees* of *Heaven*; for on the contrary it follows that these *Circles* are equally distant and proportional in their *Parts*, with regard to the *Earth*, seeing that it is our *Imagination* which conceives them round its *Center*.

Notwithstanding the *Earth* and all the other *Planets* be carried by the *Celestial matter* that surrounds them from *West* to *East*, yet they may more properly be said to *Rest* than to *move*. For seeing that *Local motion* is nothing else but the *Translation of one Body, from the Neighbourhood of those Bodies, which immediately touch it, and are considered as immoveable, into the Neighbourhood of other Bodies*, and that neither the *Earth*, nor any of the other *Planets*, are translated from the *Neighbourhood* of those parts of *Heaven* that immediately touch it, and are looked upon as immoveable, the *Earth* and *Planets* according to the *Truth* of the thing are not moved, that is, have no *motion* properly so called.

Yea, if we give head to the *Definition of motion* we shall easily discern, that that which we call the *Diurnal motion* doth not belong to the *Earth*, by itself considered, but as it is an *Aggregate of Earth, Seas and Air*, seeing it is to be looked upon at altogether at *Rest*, whilst it is whirled about by the stream of the *Heavenly matter* wherein it swims; like as a *Man* who sleeps in a *Ship*, is said to *Rest*, whilst the *Ship* is carried from one place to another. We shall also perceive, that the *Annual motion* of the *Earth*, whereby it is carried about the *Sun* from *West* to *East*, through the *Signs* of the *Zodiack*, cannot be ascribed to her, but to the *Celestial matter*, which carries this vast *Mass* round the *Sun*.

Moreover we are to mind that the *Circuits* the *Planets* make about the *Sun*, are not perfectly *Circular*: For as we see that in some parts of *Rivers*, where the *Water* whirling about, makes a *Vortex*, and carry many *Straws* along with it, some of them at the same time are whirled round about their own *Centers*, and are moved more swiftly as they are nearer to the *Center*, and tho' they incline to move *Circularly*, yet do not always describe exact *Circles*;

XV.
An Objection answered.

XVI.
The Planets may more properly be said to Rest than to move.

XVII.
Neither the Diurnal nor Annual Motion do properly belong to the Earth.

XVIII.
The Orbs of the Planets are not exactly Circular.

cles; so we may without difficulty imagine all the same things concerning the *Planets*. As is manifest from their nearer and further distances from the *Sun*, and from their Descent and Ascent in the *Zodiack*, being sometimes above the *Ecliptical Line*, and at other times under it.

CHAP. X.

That the Heavens are Fluid Bodies.

I. **I**T will not be difficult to have a certain knowledge of the Nature of the *Heavens*, if we consider that the *Matter* whereof they consist, is the same with that of the *Inferiour World*, nothing being to be found in it besides *Divisions*, *Figures*, *Magnitudes* and *Motions*. Which Modifications, wheresoever they are, still cause the same changes. And therefore we are to *Philosophize* concerning the *Heavens* no otherwise, than of our *Bodies* here below.

II. We are therefore to suppose that *Bodies* are either *Hard* or *Fluid*. *Hard* are those whose parts are so joyned, as not to be separable from one another without difficulty. Whereas *Fluid* are such whose Parts do readily give way: But how it comes to pass, that some *Bodies* do easily give way to others, and that others are not removed from their places without Force and Difficulty, we shall easily apprehend, if we consider, that these things which are moved, do not hinder other *Bodies* from entering their places; whereas those that are at *Rest*, are not without some force pushed out of them.

III. Whence it follows, that those *Bodies* are *Fluid* whose parts are tossed with various *Motions*; and those *Hard*, whose *Parts* being closely joyned together are at *Rest*. And tho' it may be our Sense may not perceive the parts of *Fluid Bodies* to be moved, yet are not we therefore to deny it; because we see the *Water* and *Air* do corrupt solid *Bodies*, which cannot be done without *Motion*.

IV. We say therefore, that the *Heavens* are no *Hard* or *Solid Bodies*, but *Fluid*. For if they were *Hard*, they could not transmit the *Light* of the *Stars*: For *Hard* and *Diaphanous Bodies*, transmit the *Light* because their Pores are rang'd in *Right Lines*, which could never be, if the vast Bulk of the *Heavens* was *Solid* like *Crystal*, or did much infringe the *Light*, as we see, that when many pieces of the clearest *Glass*, are laid one upon one another, they become very opaque.

V. If the *Heavens* were *Hard*, we could never explain how the Lower *Heaven* should be snatch'd along by the *Heaven* above it; as the *Peripateticks* imagin. For how can the *Heavenly Orbs*, supposed polish'd and even, hurry away with their *Motion* the *Spheres* that are under them? Yea when the *Sun* and the rest of the *Planets*, are whirl'd about round their *Center*, as hereafter shall be declared, no reason can be assign'd, why they should not as well be carried in the *Liquid Ether*. And indeed all the Antient *Philosophers*, before *ARISTOTLE*, were of Opinion that the *Stars* moved in the *Heavens* like *Fishes* in the *Sea*. And *Astronomers* are of the same Mind, who have observed that *Mercury* and *Venus* have sometimes got above *Mars*, and come down again, which could never be if the *Heavens* they move in were *Solid*.

VI. The same may be evinc'd by the *Comets* which are found to be above the *Region* of the *Moon*, and to slide through those *Ethereal Spaces*, which could not be without those *Spaces* were filled with a *Fluid Body*. The *Astronomers* have also observed, that the *Medicean Stars*, do roul about *Jupiter*, as *Venus* about the *Sun*, which likewise proves the Fluidity of the *Heavens*.

VII. Neither only are those *Heavens Fluid*, which contain *Mercury*, *Venus*, *Mars*, *Jupiter*, *Saturn*, and our *Earth*, together with the *Moon* its Companion, but the *Matter* of the *Sun* it self is also *Fluid*, and is continually whirl'd about its own *Axis*, as is evidenced from the *Motion* of the *Spots* about the *Body* of the *Sun*; for they are not generated in the *Air*, as some have supposed, but in the very *Body* of the *Sun*. For at first they are seen in the midst of the *Sun's Body*, and near to his *Ecliptick*, and never towards the *Poles* of the *Solar Body*. This is confirmed by many *Astronomers*, who at great distances of *Place*, have observed the very same *Spots*, at the same time, and in the same places. Now that the *Sun* doth not only move these *Spots*, but also the *Planets* that are about him, appears from hence, that the nearer any *Planet* is to the *Body* of the *Sun*, the swifter it is turn'd about. And the same is to be conceived concerning that vast *Space*, which is found about every *fixt Star*.

VIII. But you'll say first, that the *fixt Stars* observe the same distance from one another, which could not be if they wandred in a *Fluid Heaven*, changing their places, as is evident concerning the *Planets*, who oft enter one anothers *Orbs*. I answer, that the equal distance the *Stars* keep, doth not prove the *Solidity* of the *Heavens*, but that they possess some determinate *Orbs*. For the *fixt Stars* are not placed in the Circumference of one *Sphere* as some imagin, but every one of them hath its own *Space* or *Orb*; and because they observe the same Order and Proportion amongst themselves, therefore are they called *Fixed*.

IX. In the Second place you'll say, If we suppose the *Heavens* to be *Fluid*, it cannot be conceived how *Solid Bodies* can be carried about in them, seeing that they have not so much Power, but do readily give way to *Hard Bodies*. And indeed what likelihood is there that, that which is *Hard* and *Solid*, should be hurried along by that which is *Fluid* and *Weak*? I answer, that it must indeed be confessed, that *Fluid Bodies* are not of so great force, as those that are *Solid*, to hinder the motions of other *Bodies*; for seeing they having a motion themselves, and that motion is not contrary to motion, they do not resist them so much as *Solid Bodies*. But for all this it cannot be denied, but that the motion of *Fluids* where determin'd one way, doth carry all *Hard Bodies*, along with it. As appears in a *Stone*, which the *Water* of the *River* carries along with it, so long as it is not detained by some *External Cause*. And therefore there is good ground why the *Globe* of our *Earth*, resting in the pure *Ether*, should easily be carried about by its *Heaven*. In like manner as we see *Straws* on the surface of the *Water* carried about by the whirling round of the *Water*, whilst some of them whirl at the same time about their own *Centers*, being all of them moved the swifter, by how much the nearer they are to the *Center* of the said *Whirl-pool*.

X. The Reason whereof is, because a *Hard Body* encompass'd with a *Fluid*, and Resting in it, lies there as in an Equal Poise; and how great soever it may be, will be easily carried away by a little force, whether that Force come from abroad, or that the *fluid Body* it self, wherein it is contain'd, be wholly carried one way; as the Course of *Rivers* tends towards the *Sea*; or as the *Air*, when the *East-Wind* blows, is carried towards the *West*; which whenever it happens, any *hard Body* that is in that *fluid*, must of necessity be carried along with it.

XI. Hence we may infer, that seeing the *Heaven* doth on all sides surround the *Earth*, and drive all the *Bodies*, that are on the surface of it, towards its *Center*, it doth by this means keep it from Falling: So that the *Earth* cannot but be carried along by it, and being thus without any *motion* of its own, yielding only to that of the *Heavens*, it may with good reason be said, to be at Rest. And the same may be said of the *Sun*, who is hindered by the *Globuli* of the *Second Element*, which surround him, from flying from the *Center*; and the lower *Globuli*, by those above them; and the utmost, by those of the contiguous *Vortexes* of the *fix'd Stars*, who by a contrary pressure do keep them within their Bounds.

C H A P. XI.

How the Heavens were disposed at first, and of their divers Motions.

I. IT will not be difficult to demonstrate the first Disposition of the *Heavens*, or that order which the *Heavenly Orbs* now observe, and did from the Beginning, by supposing only a few things, which we have proved in the *Fourth Part*.

II. First, That there is no *Vacuum* in Nature; for seeing that *Space* is not distinct from a *Body*, it must necessarily follow, that wheresoever *Space* is found, there must be a *Body* also.

III. That there can be no penetration of *Dimensions*; for seeing that the Conception of a *Body* involves *Extension*, and by it excludes all other *Bodies* out of the same place with it, it is evident that many *Bodies* cannot be contain'd in the same place.

IV. Whatsoever is moved, is moved in a *Circle*; for seeing all places are fill'd with *Bodies*, it is clear, that one *Body* cannot be removed out of the *Neighbourhood* of some *Bodies*, into the *Neighbourhood* of others, without being mov'd in a *Circle*. So that when any *Body* enters into a place, the *Body* that was there before leaves it, and enters into the place of the next, and so on to the last; which at the same instant of time enters into the place the first *Body* hath left.

V. It will not be amiss for us also to explain what we intend by the Words, *Vortex*, *Center*, *Ecliptick*, *Poles* and *Axis*. By the word *VORTEX* we understand, a vast number of parts of *Matter*, which move together about the same *Center*. By the *Center* of a *Vortex* we mean, the point about which all the parts of *Matter* that constitute the *Vortex* do move. And because when a *Vortex* turns round, all the Points of the *Surface* describe *Crooked lines*, which resemble *Circles*, except two that turn about themselves, we call those two Points the *P O L E S*; and the *Circle*, which is

equally distant from the two *Poles*, we call the *ECLIPTICK*; and the *Right line*, which reacheth from one *Pole* to the other, passing through the *Center* of the *Vortex*, we call the *A X I S*.

These things premis'd, we say that the Parts of the *Universe*, being in the Beginning of the *Creation* put into *motion*, must naturally run themselves into several *Vortexes*; for these *Particles* being of different bulk and figure, and unable to move forwards in *Right lines*, because of their various determination, they were forced to move in *Circles*, and by this means did constitute *Vortexes* of a stupendous Magnitude, according to the Quantity of the *Matter*. For it is an unquestion'd Truth amongst *Philosophers*, that a *Body* which is dash'd against another, must of necessity rebound back from it, and so be carried in a *Circle*, that it may continue its *motion*, which may be proved by many Experiments. For the *Vortexes* of the *Air*, or those of the *Water*, which we see in *Rivers*, are caused, because the *Vapours* that make the *Wind*, and the running *Waters*, being beat back by occurring *Bodies*, are hindered from moving strait forwards: and therefore being reflected on one side, must necessarily turn round, because the subsequent *Air*, or *Water*, is successively push'd forwards after the same manner as the first, and so must twist in and be carried Circularly.

That this was the Original of the *Vortexes* is unquestionable, by those who admit the *Matter* of the *World* to have been divided into particles of different *Magnitude* and *Figure*; and that they had as much *motion* from the beginning, as there is now found in the whole *Universe*. Because these *Particles* dashing one against another, must needs be carried round about divers *Points*, and so run together into divers *Vortexes*. So that all the *Particles* that were whirl'd about the *Sun S*, did constitute the *Vortex*, terminated by A, Y B, M, and that others which rould about the *fix'd Stars* L, C, O, K, compos'd other *Vortexes*.

We admit only two visible *Heavens*; the first, that whose *Center* the *Sun S* is, in which we live, and wherein *Venus*, *Mercury*, the *Earth* and the rest of the *Planets* are contained, and in which they are rould about with various motions. And the *Second Heaven* is that which contains innumerable *Vortexes* Z L Z, M C M, Y O Y, T K T, which have *fix'd Stars* in their several *Centers*, and on every side surround the *First Heaven S*. Whatsoever reacheth beyond these *Heavens*, does not fall under our Senses, tho' we conceive it Immenſe, and not confin'd within any Limits, being therefore called an *Expansion* or *Firmament*, from its vast and *Indefinite Extension*.

The Disposition therefore, and ordering of the several *Bodies* of this *World* was made, when the *Planets*, and all other *Bodies* that lay confounded together in the *Chaos*, were separated by the subtil *Matter* flowing between them, and got into several places, according to the thickness and solidity of the *Matter*. Whence it is evident, that the *Forms* of the *Vortexes*, are the very first and most simple *Forms* that were ever introduced into the *Matter*; they are the *First*, because they are the immediate product of the *Laws* of *Motion*; and the most *Simple*, because they suppose none before them; and because all other *Forms* depend on them, as on their *Principles*.

VI. How the Vortexes came first to be.

VII. The Divisibility of Matter being suppos'd, the Vortexes could not but be made this way.

Figure 20.

VIII. That there are but two visible Heavens.

IX. How the Vortexes came to be divided, and what the Form of them is.

X. There is one Difficulty seems to arise from the Disposition of these *Great Bodies*, viz. how these *Vortexes* could fall into such a *motion*, as that one should not hinder the other: For it is hard to conceive how *Bodies* of so great a Bulk should not interfere with one another in their Circumvolution, seeing that according to the *Laws* of *Nature*, the *motion* of one *Body* is turned aside by the meeting of another.

XI. This Difficulty may be answer'd by shewing, that these *Vortexes* may be so placed, that their *Motions* will rather further than hinder each other; that is, if we conceive them so ranged, that the *Ecliptick* of one, (or that part of the *Vortex*, which whirling about its *Axis* describes the largest *Circle*) do correspond to the *Poles* of the other: For by this means they will so agree together, and move so freely, as not in the least to hinder one another.

XII. Yea, if we examin the matter, we shall find that the *Heavenly Vortexes* cannot be so, but that the *Poles* of one must touch the *Ecliptick* of another. As suppose the first *Vortex*, whose *Center* is S, be moved from A, toward Y; another *Vortex* contiguous to it, whose *Center* is O, and another whose *Center* is C, must touch it in those *Parts* that are most remote from both the *Poles* A and B, of the *Vortex* S. For if we should suppose the *Poles* of two *Vortexes* to touch one another, they will either by a like determination of *motion* be carried the same way, and so will run one into another; or they must by a different determination be carried oppositely to one another, and so clashing in their *Motions*, they will never be able to continue them long; and therefore to the end their *Motions* may not interfere together, the *Vortexes* must be so ranged, that the *Pole* of one *Vortex* may not touch that of another, but the *Ecliptick*, or those *parts* which are most remote from them; forasmuch as by this means they support and preserve one another.

XIII. The First *Heaven*, in which the *Sun* S is the *Center*, and by the force of whose *motion* the other *Planets* are wheel'd about, is most swiftly turn'd round by it; for the *Sun* being with great celerity whir'd about its own *Axis* A B, carries the nearest *parts* along with it, and imparts his *motion* unto them: So as that the *parts* nearest to him are more swiftly moved, than those that are more remote, and so on to the *Region* of *Saturn* H N Q R, where the *parts* of the *Heaven* are moved slowest of all. The Reason whereof is, because those *parts* that are nearer to the *Center* of the *Vortex*, are less than those further off, and consequently are more swiftly moved. And that the *parts* towards S, are less than those that are about H N Q R, is evident; for that if they were bigger or equal, by being so near the *Center* of the *Sun*, they must needs be more swiftly moved, and by consequence possess themselves of Higher places.

XIV. According to this Proportion therefore, the *motion* of the *Celestial Matter*, grows by degrees more slow to a certain term, beyond the *Region* of *Saturn* H N Q R, where the highest or utmost *parts* of this our *Vortex* begin to be more swiftly moved, not by the *Sun*, as is apparent enough; but from the Neighbouring *Vortexes*, which surround the First *Heaven*; for they being unequal, do variously shake the *Surface* of the First *Heaven*,

and thereby conduce to the swiftness of those *Parts*. This great degree of their swiftness, appears from the swift *motion* of the *Comets*.

From what hath been said, we may gather these two things: First, That the *Vortexes* are circularly moved; for being hindred by other *Bodies*, from proceeding in a *Right motion*, they are forc'd to change the same into a *Circular*, and therefore must continually be whir'd round.

Yet is it not necessary that these *Vortexes* therefore should be exactly *Round*; for tho' they counterballance one another by their equal Force, yet is not this Force equally dispers'd through all their *parts*; because those which are about the *Ecliptick* of one *Vortex*, are always more strong than those that are towards the *Poles* of another: Which makes (since the *Ecliptick* of one *Vortex* commonly meets with the *Poles* of others) the *parts* that are about that *Ecliptick*, to advance more towards the *Poles* of other *Vortexes*, than the *parts* which are about the *Poles* of other *Vortexes*, do advance towards this *Ecliptick*. We see also in the precedent *Figure*, that the Neighbouring *Vortexes* make the *Vortex* S, which is between them, irregular.

Secondly, We may gather from what hath been said, that the *Motions* of the *Vortexes* are perpetual, since there is nothing that can be assign'd that should change or diminish their *Motions*. For a *Body* therefore only ceaseth to move, because by running against another *Body*, it imparts its *motion* unto it, which cannot happen to the *Heavens*, because they have no *Bodies* at Rest; or slowly Moved, to which they may communicate their *Motion*, and so come to lose it. For the Law of *Nature* requires, that every thing, inasmuch as it is single and undivided, should remain in the same state, nor ever be changed; but from *External Causes*; and since no such *Causes* are in the *Heavens*, but all the *Vortexes* do comply together, we are rather to conclude, that they maintain and preserve one another.

As to the Bigness of the *Vortexes*, we have no reason to think, that all those which were the result of the First Division of the *Matter*, were all of them *Equal*. For as the only Reason we have to believe, that the vast number of *Vortexes* are not confounded one with another, is, because their Forces are equal and opposite; we may also well imagin, that a *Vortex*, which is less than those that are about it, will for all that preserve its station amongst them, if we consider that the Defect of its Bulk may easily be made up by its greater degree of Swiftness in *motion*. This Inequality of the *Vortexes* is represented to the Eye in this *Figure*, where the *Vortex* S, tho' greater, cannot destroy that of O, nor K, tho' lesser than it.

We may gather from what hath been said, why gross and Earthly *Bodies*, are Heavy about the *Centers* of the *Vortexes*; tho' *Light*, when they are at a distance from them. For seeing these *Bodies* derive their *motion* from the subtil *Matter* wherein they swim; which *Matter* is actually turn'd Round, and inclin'd to move forwards in *fract Lines*; it by this means communicates its *Circular motion* to those thicker *Bodies*, which it carries along with it; but not the Force it has in proceeding in *right Lines*, save only so far as that Force accompanies the *motion* it imparts to them.

But

XV. The *Motions* of the *Vortexes* are *Circular*.

XVI. It is not necessary that the *Vortexes* should be exactly *Round*.

XVII. The *Heavens* are moved continually.

XVIII. A small *Vortex* may preserve it self, amongst others that are greater.

XIX. What *Bodies* are said to be Heavy.

But because the *subtil Matter*, which is about the Center of the *Vortex*, hath much more agitation than is required to *Circular motion*, (for every of the *Particles*, besides the *Circular*, or *Common motion*, are also variously moved) it so happens that those *Bodies* which have less *motion*, have also less *force* to continue their *motion* by *Right lines*, and by this their weaker *force*, are forc'd to give way to those, which with greater *force* press on towards *Strait lines*, and therefore must tend towards the Center of the *Vortex*, that is, become so much the more *heavy*, as they are more *solid*.

XX.
What Bo-
dies are
said to be
light.

But when *Earthly Bodies* are at a great distance from the Center of their *Vortex*, seeing the *Circular motion* of the *subtil Matter* is very intense, forasmuch as it employs almost all its *motion* in its *Revolution* about the Center of the *Vortex*, they have the more agitation, as they are more *solid*, because they follow the *motion* of the *subtil Matter* in which they swim; and therefore have more *force* to continue their *motion* according to a *Right line*: so that the *grosser Bodies*, at a certain distance from the Center of the *Vortex*, are by so much *lighter*, as they are more *solid*. For by the word *Lightness*, we understand nothing else, but the Endeavour wherewith the *Bodies* that are moved Round, tend to withdraw from the Center of their *motion*; as by the word *Heaviness* we understand that *strife*, whereby less agitated *Bodies*, or less *solid*, are thrust down towards the Center of their *motion*, by such as have more *force* than they to withdraw from it.

XXI.
The Planets
Earth
are not
Heavy.

From hence it is evidently deducible, that the *Earth* about its Center is very *solid*, but less towards the *Circumference*; as also that the *Water* and *Air* must continue in that situation wherein we see them, and that consequently they are *Heavy*. For seeing all these *Bodies* are more *solid* than the *Matter* of the *First* or *Second Element*, they cannot avoid being push'd towards the Center by it: Whereas the *Moon*, being at a considerable distance from the Center of the *Vortex* of the *Earth*, is not look'd upon as *Heavy*, tho' it be a *solid Body*; as neither *Mercury*, *Venus*, *Jupiter*, and *Saturn*, which cannot fall down towards the *Sun*.

CHAP. XII.

Concerning the Action and Motion of the Heavenly Matter.

I.
How Light
was made
in the First
Day of the
Creation.

HAVING thus been inform'd how the *Heavens* were ranged, and what Order they still keep, we are next to consider how the *Heavenly Matter* is moved, and what *Action* it exerts in them. For as soon as the *Vortexes* began to be formed, it could not be but that some part of the *Matter* of the *First Element*, made by the rubbing of the divided *particles* against one another, must be gather'd towards the Center, and from thence propel the surrounding *Globuli*, which was sufficient to make *Light*. And thus we may perceive how *Moses* is to be understood, when he saith, that *GOD* divided the *Light* from the *Darkness*, and that *Light* was in the First Day of the *Creation*: Because the *Matter* of the *First Element*, which was about the Center of each *Vortex*,

press'd the *Globuli* of the *Second Element*, and so procured the *Light*. Yea, this was in some measure effected upon the first Turn of the *Vortex*, before the *subtil Matter* run to the Center. For by the name of *Light* we can understand nothing else, than that pressure of the *Globuli* in *Right lines*, which does excite in us the sense thereof. And therefore, when it is said, that *GOD* commanded the *Light* to be, it must be thus understood, that *GOD* put the *parts* of *Matter* into *motion*, and gave them an Inclination to continue the same in a *strait Line*.

But after that the *Matter* of the *First Element*, by the continual rubbing together of the several *Bodies* was increased, it betook it self in great Quantity to the Centers of the *Vortexes* *S L C K O*, and there made the *Sun* and the *fix'd Stars* on the *Fourth Day*. For seeing that all *Circular moved Bodies*, continually strive to recede from the Center of their *motion*, and that those that are strongest recede farther than such as are weak; it follows, that the *Particles* of the *Second Element*, that are more strong than those of the *First*, because they are *solid*, do more recede from the Center of their *Motion*, and that in this their recess they push down thither all those *Particles* of the *First Element*, that are left after the filling the *Intervals*, which are between the *Particles* of the *Second Element*. Whence it follows, that about the Center of each *Vortex*, there is a *Body* only composed of the *Matter* of the *First Element*, which cannot but be of a *Round Figure* that way it turns; that is to say, If one should cut it by a *Flat* parallel to the *Ecliptick*, in what part soever this Section should be made, it would be always a *Circle*: For otherwise it must be supposed, that some *Particles* of the *Second Element* are not so far removed, as they might be, from the Center which they describe, which is impossible.

Now that *Body* of the *First Element* which is formed in the Center of a *Vortex*, is commonly called a *Star*; so that by this word *STAR*, we understand nothing else, but a *Body* compos'd only of the *First Element*, which has been driven by that of the *Second*, towards the Center of each *Vortex*.

It is evident from what hath been said, that the *Matter* of the *First Element*, is not every where moved alike, but more strongly in the *Bodies* of the *Lucid Stars*, than without them in the *Globuli* of the *Second Element*. For the *subtil Matter* gather'd together in the *Sun* or *fix'd Stars*, hath a greater *force*, by reason of the Consent of its Parts to all those swift *motions*, by which it pusheth forwards the *Aethereal Matter*, or the *Heavenly Globuli*. But without the *Stars*, and between the *Globuli*, its *force* is diminish'd, and by being divided, is much weaker: So that every one of its *Particles* are push'd this way and that way, by the *Globuli*, and thereby are forc'd to comply with their various *motions*. Hence it is, that the *Matter* of the *First Element*, because of the exceeding smallness of its Parts, is forc'd to change its *Figure*, and to be toss'd with various *motions*. For as it is tost amongst the *Globuli*, it hath several *motions*; first, its own proper *Motion*, by which it continually changeth the figure of its little particles, to be fit to fill up exactly all the Corners

II.
How the
Sun and
fix'd Stars
were made
the Fourth
Day.

Figure

III.
What we
understand
by the
word
Star.

IV.
The most
subtil Mat-
ter is most
strongly
mov'd
within the
Bodies of
the Stars.

it passeth through. Next it hath a *Circular motion*, which is common to all *motions* that are moved together. And lastly it hath a *Straight motion*, whilst by the *Circular motion* of the *Vortex*, it is thrust in great abundance towards the Parts that are most remote from the *Poles*.

V. And tho' there can be but one *Proper motion* assign'd to a thing, yet doth not this thwart the Truth of what we have just now said, because tho' this *motion* hath several names, yet it is still but one and the same, from the *Center* to the *Circumference*, by a *right Line*, tho' in its going forth it may undergo several *Figures*; even as the *motion* whereby any *Liquor* is transmitted through a *Channel* or *Pipe* is said to be one, tho' it run to the term to which it is directed, in one place through a *square Pipe*, in another through a *Triangular*, in one through a narrower, in another through a wider *Pipe*.

VI. We are also to take notice of some difference there is between the *Globuli* of the second *Element*, because the Bigger, as being more *Solid*, are more suited to receive a swift *motion* from the matter of the first *Element*, than the Less, and therefore they are more swiftly moved, and withdraw further from their *Center*.

VII. Next, we are to consider that the first *Element*, is continually carried towards the *Center* of each *Vortex*, from other Neighbouring *Vortexes* about it, by those Parts which are nearest to the *Poles*, where there is least resistance, that so they may make up again that which is lost: But that the same matter breaks out of its own *Vortex* into others, by the *Ecliptick* or those parts which are furthest from the *Poles*. For let us suppose *A B*, to be the *Poles*, about which the *Vortex* in which we are, *Whirls* round, *H* and *Q* to be the *Ecliptick*, or Parts most remote from the *Poles*, where the *motion* is the *Swiftest*. Let us also suppose the *Vortex* to be *A Y B M*, round about which four others *Vortexes* *L C K O* rowle, so as to touch *O* and *C*, at their *Poles*, and the other two *K* and *L*, in those Parts that are most remote from their *Poles*; I say, this supposed we may easily guess, that the matter which strives to withdraw from the *Axis* *A B*, of our *Vortex*, doth with greater Force tend towards the Parts *Y* and *M*, than towards *A* and *B*. The reason is, because the most subtil matter in *Y* and *M*, meets with the *Poles* of the *Vortexes* *O* and *C*, where there is no great Force of Resistance; whereas in *A* and *B*, it meets with those parts of the *Vortexes* *K* and *L*, which are most remote from their *Poles*, and have a greater Force of moving from *L* and *K*, towards *S*, than the Parts about the *Poles* of the *Vortex* *S*, have to tend towards *L* and *K*; and therefore it is manifest, that the most subtil matter which is in *K* and *L*, must move on towards the *Center* of our *Vortex* *S*, and that that which is in *S*, must tend towards the opposit *Vortexes* *C* and *O*. So that as much of this subtil matter, as gets out through *Y* and *M*, so much of the same matter enters, from the other *Vortexes* *L* and *K* through the *Poles* of our *Vortex*.

VIII. But there is no such passage of the matter of the second *Element* from one *Vortex* to another; for being whirled round as well as the subtil matter, it endeavours to preserve its Swiftness, but would certainly lose much of the same, if it should wan-

der out of the limits of its own *Vortex*, since the *motion* is so very slow in the *Polar Parts* of the other *Vortexes* *M* and *Y*, that it cannot meet with any free entrance there. Yea, tho' we should suppose, that the *Aethereal Globuli* should pass from the *Poles* of one *Vortex*, towards the *Center* of another; and that all the matter both of the first and second *Element*, contained in the *Vortex* *L*, at the very same moment of time, had begun to move, from the middle place between the *Centers* *S* and *L*, towards *S*; yet we shall easily understand, that the said subtil matter will arrive sooner at the *Center* *S*, than the *Globuli* of the second *Element*. Because the Agitation of the first *Element* far surpasseth that of the second, and hath always an open passage, through those little *Angles*, which cannot be fill'd up by the matter of the second *Element*. To which we may add, that the matter of the first *Element*, by passing through the narrow spaces left by the *Globuli*, meets with no impediment, nor loseth any part of its Swiftness, seeing that according to the Laws of *motion*, it always endeavours to recede from the *Center*, and hath a force to persevere in its Swiftness.

IX. Having thus seen how the Matter of the first *Element*, which is impatient of Rest, breaks forth from one *Vortex* to another; we are to enquire how the said matter is moved amongst the *Stars*. Consider we therefore, that a part of the most subtil matter, in the Space *d e f g*, where we place the *Sun*, moves from *A*, by a *right line* to *d*, and there meeting with the *Globuli* of the second *Element*, beats them back towards *B*; and that contrarily another part of the said matter comes from *B* to *f*, and there drives before it the *Globuli* of the second *Element* which it meets with, towards *A*, and that immediately thereupon, as well the matter about *d*, as about *f* becomes reflected towards all the parts of the *Ecliptick* *e g*, and doth equally drive before it all the adjoining *Globuli* of the second *Element*, and lastly gets away into *MY*, through the materials that separate those *Globuli*, about the *Ecliptick* *e g*.

X. Whereupon this Space must needs be *Spherical*, because the matter of the first *Element*, which is entred into the *Body* of the *Sun* by its *Poles* *A B*, must equally beat back all the circumjacent *Globuli* of the second *Element*, as well those, against which it is only obliquely reflected, as the other against which it pusheth in a direct *Line*; after the same manner as we see, that a *Glass pipe* is formed Round, because the *Air* driven through the *Iron pipe*, with an equal force spreads it self round, and equally preffeth it on all sides.

XI. The matter of the first *Element* without the *Stars*, or whilst it wanders between the *Globuli* of the second *Element*, hath a various *motion*. For first it hath a *Proper motion*, whereby it runs to the filling up of the little Spaces left by the *Globuli* of the second *Element*, which the diversity of *motion* changeth every moment. And it hath also a *Circular motion* about the *Poles*, common to the whole *Heaven* *A M B Y*; because that which is contained between the little spaces of the *Globuli*, follows the *motion* of them. As *Water* contained in a *Barrel*, follows the *motion* of it, and accommodates its self to its *Figure*. It hath also a *Straight motion*, from the *Poles* *A B* to the *Sun*; and likewise from the *Sun* to the *Ecliptick* *Y M*, according-

How the matter of the first Element is moved amongst the Stars.

The motion of the matter of the first Element is the cause of the Roundness of the Stars.

The motion of the subtil matter amongst the Globuli is various.

ing to the Law of motion, that things which are circularly moved, always tend to recede in a right Line, from the Center of the Circle they describe.

XII. VVhence it appears that the matter of the first Element, collected in the Center of the Sun and first Stars hath a very great Force, because the motion of all its particles do readily agree and conspire together, to push forward the Globuli with an equal Force: But this Force grows weaker out of the Body of the Stars, because it spends the greatest part of its Agitation, in changing the Figures of its little Particles, to the end it may exactly fill all the little Corners through which it passeth.

XIII. VVherefore whilst the matter of the first Element, passeth through the Triangular intervals 1 and 2 of the Globuli touching one another, it must needs assume a Triangular Figure, and become shaped into striate Particles 3 and 4 bent a contrary way. It is not easy to determin the length of those Particles, because this depends on the slenderness or abundance of the matter, whereof they are made: But it is sufficient to conceive them like little Columns, with three Notches round them like a Screw; so that in their whirling round, they may pass through those narrow passages 1 and 2 of a Triangular Form. For seeing that they are longish, and with a most swift motion pass between the Globuli of the second Element, which touch one another, whilst the Globuli in the mean time by a different motion are whirled round, about the Poles of the Heavens, we clearly understand, that their Notches must go winding about, like those of Screws, which winding must be more or less according as they pass through parts that are more remote from the Axis of the Vortex, or nearer to it, because they move more swiftly in those, than in these.

XIV. As to the Globuli of the second Element, of which the Vortexes consist, they are not all of the same bigness; for those that are nearer to the Star and its Center, are less than those that are farther off, and consequently absolve their Circle in a less time. VVhich inequality of their Magnitude, extends it self to the Region of Saturn H N Q R, where the parts of Heaven move most slowly. Yet beyond that Orb it is probable, that the Globuli are all of an equal Magnitude, and that the Higher move more swiftly than the Lower. So as that the Higher must move more swiftly towards M and Y, than the Lower towards H and Q. The reason whereof is amongst other things, that the bordering Vortexes being unequal, the motion of the subtil matter, between those unevennesses of the surface, becomes much accelerated.

CHAP. XIII.

Of the Heavenly Sphere and its Circles.

I. BY the word Sphere we understand that common instrument of a round Figure, consisting of several Circles, invented to explain and represent the Heavenly motions, and the Fabrick of the whole VVorld. This Sphere hath a little Ball in the midst or Center of it, with an Axis through it, the Extremities whereof are called Poles, about which the whole Body of the Heavens is supposed to turn round in the Space of 24 hours.

The Axis of the World is a right Line, which extending from one Pole to the other, passeth through the Center of the World. By this the Earth is said to be supported: Not that there is indeed any such visible Axis in the Globe of the Earth, which is terminated in the Heavens, and whereby the Earth is sustained; but only that such a Line is understood, which passing through the Center of the Heaven and Earth, reacheth to the utmost Heaven, and ends at two points, which are called the Poles of the World.

The Poles therefore are nothing else but the Extremities of the Axis, or two Points in the highest Heaven, Diametrically opposit, about which the whole bulk of the Heavens is conceived to be whirled about. The one of these Poles is always visible to us, and from its nearness to the constellation of the Bear is called Arctick, the other which is always hid from us, being from its opposition to the former called Antarctick.

The Northern Pole is reard in sight on High,
The other hid under our Feet doth lie.

There are ten Circles in an Artificial Sphere, six whereof are called Greater, whose Diameter passeth through the Center of the World, or which divide the Sphere into two equal Parts, and these are the Horizon and Meridian (between which standing immoveable, the other Circles are turned round) the Aequator, the Colure of the Solstices, the Colure of the Equinoxes, the Zodiack or broad Circle, and the middle line thereof, which is called the Ecliptick. The four lesser Circles are those whose Diameter doth not pass through the Center of the World, or which divide the Sphere into two unequal Parts. They are the Tropick of Cancer, the Tropick of Capricorn, the Arctick and Antarctick Circle, which also with the Aequator are called Parallels, as being at an equal distance from each other.

The Aequator or Aequinoctial Circle, which is the chiefest of all the rest, is that Circle, which in all its parts is equally distant from the Poles of the World, which it divides into the Northern and Southern Hemisphere. By the Greeks it is called the Even-day Circle, because the Sun twice in a year, that is about the 10 of March, and the 13 of September intersecting the same, makes two Equinoxes, by rendering the Days and Nights equal, through his equal stay above and under the Horizon, because the Aequator intersected by the Horizon, becomes divided into two equal parts, one Superior, and the other Inferior.

The Zodiack is a greater Circle superinduced over the other moveable Circles, unequally distant from the Poles, and intersecting the Aequinoctial at two opposit Points; so that its middle line which is called the Ecliptick, hath one part of it inclining to the North Twenty three degrees, and Twenty eight minutes, according to the Antients, and the other part of it as many degrees reaching towards the South. This Circle is conceived Broad, because the Planets which move through it, do not all of them keep the same tract, but whilst the Sun takes its Course through the midst of this Circle, along the Ecliptick they swerve to the North and South. The Points at which the Zodiack Intersects the Aequator, are called the Aequinoctial Points: because when the

Sun

II. *Sun* reacheth them, it makes *Day* and *Night* of equal length. And the *Points* by which the *Ecliptick*, declines furthest from the *Aequinoctial*, are called the *Solstitial Points*, because when the *Sun* comes to them he seems to stand still. The *Zodiack* is furnished with twelve *Signs* or *Constellations* of which hereafter.

VII. The *Colures* are two greater *Circles*, which intersecting one another in right *Angles* at the *Poles*, do intersect all the other moveable *Circles*, dividing them into four equal *Parts*. For the *Colure* of the *Solstices* passeth through the *Poles* and the *Solstitial Points* of *Cancer* and *Capricorn*; but the *Colure* of the *Aequinoxes* is described through the *Poles* of the *World*, and the *Aequinoctial Points* of the *Zodiack*, at *Aries* and *Libra*. The use of the *Colure* is to mark out the four *Cardinal Points*, viz. the beginning of *Aries*, where whilst the *Sun* is, the *Night* is equal with the *Day*, and the *Spring* begins; the beginning of *Cancer*, where the *Sun* makes the longest *Day*, and begins *Summer*; the beginning of *Libra*, where the *Sun* makes *Day* and *Night* equal, and begins *Autumn*; and the beginning of *Capricorn*, where the *Sun* makes the shortest day, and *Winter* begins.

By *Crab* and *Capricorn Solstice* is made,

The *Ram* and *Ballance* equal *Light* with *Shade*.

VIII. The *Horizon* is the utmost *Circle* in a *Sphere*, encompassing all the rest, and is that *Circle* which is equidistant from the *Vertical Point* of every place; and therefore is called by the Greek *Horizon*, that is to say, *Terminator* or *Finisher*, because it boundeth our sight. For when standing in a *Plain* we take a *Prospect* round about, we see the *Heavens* every where, as it were touching the *Earth*; from which *Commixture* of the *Heaven* and *Earth* as the *Stars* get upwards, they are said to *Rise*, and when they sink beneath it are said to go down. Tho' the *Horizon* with regard to every particular place of the *Earth* be *immoveable*, yet considered in general it is mutable, forasmuch as whilst we *Travel* from one place to another, we also pass from one *Horizon* to another.

IX. The *Meridian* is a greater *Circle* which passeth through the *Poles*, and the two *Points*, the one directly over our heads, called the *Vertical Point*, and the other opposit to it, under our Feet called the *Nadir*. This *immoveable Circle*, within which the other *Circles* are moved, is called the *Meridian*, because when ever the *Sun* reacheth it, he makes *Noon* or *Midday*, by dividing the *Day* into two equal *Parts*. Whence it appears, that the *Altitude* or *Elevation* of the *Pole* in every *Country*, is nothing else but that *Arc* of the *Meridian*, which is intercepted betwixt the *Horizon* and the elevated *Pole*, and whose complement to the *Zenith* or *Quadrant* of the *Circle*, is always equal to the *Altitude* of the *Aequator*.

X. The *Tropick* of *Cancer* is a less *Circle*, Parallel to the *Aequator*, passing through the *Northen Solstitial Point* of the *Zodiack*. The *Tropick* of *Capricorn*, is a less *Circle*, Parallel to the *Aequator*, passing through the *Southern Solstitial Point* of the *Zodiack*. They are called *Tropicks*, that is to say *Turn-agains*, for that as soon as the *Sun* in his withdrawing from the *Aequator* reacheth them, he begins to return again towards it. Their distance from the *Aequator* is 23 Degrees and an half; that

being the furthest *Elongation* the *Sun* ever makes from that *Line*; wherefore, also it is called the greatest *Declination* of the *Sun*.

The *Artick* or *Northen Polar Circle*, is a less *Circle*, Parallel to the *Aequator*, passing through the *Pole* of the *Zodiack*, near the *Northen Pole*. The *Antartick* or *Southern* is a *Circle* passing through the other *Pole* of the *Zodiack*, near to the *Southern Pole*. These two *Circles* are at the same distance from the *Poles*, as the *Tropicks* from the *Aequator*, that is 23 Degrees and an half. They have also this common use with the *Tropicks*, that they serve to distinguish the *Zones*, the *Torrid* being comprehended within the *Tropicks*; and the *Frigid* within the *Polar Circles*; but the *Temperate Zones* lie between the *Polar Circles* and the *Tropicks*.

XI. All these *Circles*, the *Aequator*, *Ecliptick*, *Meridian*, with the *Tropicks* and *Polar Circles*, are applied to the *Terrestrial Globe*: For the *Earth* also hath its *Aequator*, commonly called the *Line*, corresponding to the *Celestial Aequator*; and every place on the *Earth* hath its own *Meridian*. And these *Circles* are exceeding useful to distinguish the various *Situation* of *Places*, as well as to the *Art* of *Navigation*, and to the *Knowledge* of *Geography*. For since we may distinguish the *Earth* as well as the *Heaven*, in *Length* and *Breadth*; the *Latitude* of any *Place* is nothing else, but a *Portion* of the *Meridian*, intercepted between the *Aequator* and that *Place*. Wherefore, those who live under the *Aequinoctial* have no *Latitude*; whereas they have the greatest *Latitude*, who are at the greatest distance from the *Aequator* under the *Poles*. The *Latitude* of a *Place*, is the same with the *Elevation* of the *Pole*, for they who live under the *Line*, see both the *Poles* in their *Horizon*, but as we withdraw from the *Aequator*, one of the *Poles* is *Elevated* above our *Horizon*, and the other depressed beneath it.

But the *Longitude* of a *Place* is taken in the *Aequator*, and is nothing else but a *Part* of the *Aequinoctial Circle* intercepted between the *Meridian* of any particular place (suppose *Paris*) and the first *Meridian* appointed by the consent of Men, which *Meridian* is conceived to pass through the *Islands*, of *Azores*.

XII. A *Sphere* is either *Right* or *Oblique*. A *Right Sphere* is that whose *Horizon* passing through the *Poles* of the *World*, cuts the *Aequinoctial* at *Right* or *Equal Angles*.

XIII. An *Oblique Sphere*, is that whose *Horizon* cuts the *Aequator* at unequal *Angles*, and doth not pass through the *Poles* of the *World*.

XIV. They therefore have a *Right Sphere*, who live under the *Aequator*, and they an *Oblique* who live under the *Tropicks*. Whence it appears that the *Sun* and the rest of the *Stars* in a *Right Sphere* seem to rise and set in *Right Lines*, both the *Poles* lying on the *Horizon*; whereas in an *Oblique Sphere* EFGH, (where one of the *Poles* E, and the *Axis* of the *World*, is more or less obliquely inclin'd towards either side of the *Horizon*) they are seen to rise above the *Horizon*, come to the *Meridian*, and set beneath the *Horizon* obliquely. For any one may easily apprehend, that where both the *Poles* lie on the *Horizon*, there the *Aequator* must be *Vertical*; and seeing it cuts the *Hori-*

zon at Right Angles, the Stars must needs arise and set in Right Lines; and in like manner, whatsoever else is in the Heaven, forasmuch as all the Circles, which they describe parallel to the Equator, will likewise cut the Equator at Right Angles. And on the contrary, those that live between the Equator and the Elevated Pole, because of the Oblique ascent and descent, have some Stars always in sight, and others ever out of sight.

CHAP. XIV.

Of the SUN.

I. From what hath been already said of the *Formation* of the Heavenly Matter, we may easily understand how the Sun was formed at first. For whilst the Globuli of the Second Element, being more solid than the Matter of the First, withdrew from the Center, betaking themselves to the Circumference, the most subtil Matter being increased to too great a quantity (from the continual rubbing of Bodies against one another) to be contained in their Intervals, rush towards the middle part, where being tost with different motions, and most swiftly whirled about its Center, it constituted the Sun, and the other fix'd Stars. For seeing that our World, in the midst whereof the Sun's Seat is, and which extends it self beyond the Sphere of Saturn, doth constitute one great Vortex, whose fluid and transparent Matter is circularly moved; it must follow that the Globuli of the Second Element will strive to recede from their common Center, and as far as their Figure and Motion will permit, come nearer together, and lye upon one another; which they cannot do, without driving the Matter of the First Element, whereof there is greater store than is needful, to fill their Intervals, towards that place which they have left; so that it cannot be, but that about the Middle of the Vortex, there must be a great concourse of the Matter of the First Element; which we take to constitute the Body of the Sun.

II. Accordingly we may define the Sun to be a Lucid Body, consisting of the Matter of the First Element, gather'd together in the Center of a Vortex, in the room of the Globuli that recede from it.

III. From the Account we have here given of the Sun's Formation, we gather first, that the Sun must be of a Round Figure; because the most subtil Matter entering the Sun at either of its Poles, continues its course in a Right line, until it meet with the Globuli of the Second Element, which are about the opposite Pole, and running against them, drives them forward by the force of its motion, and thereupon is immediately reflected, and turns round in all its parts towards the Ecliptick, and so drives forwards the adjacent parts of the Second Element, that are next to the Center of the Star, and by this means makes the Sun to be Round: So that if it should be intersected by a Plain; parallel to the Ecliptick, in whatsoever part the Section be made it will always be a Circle. For otherwise it would follow, that some parts of the Second Element, do not recede so far as they can from the Center of the Circle they describe; but this is impossible, considering the Fluidity of the Heavens.

In the Second place, we infer from hence that the Sun is Lucid; because the Matter of the First Element, gather'd together in the Center of the Vortex, by pressing every way upon the Heavenly Globuli, (besides the motion they have, as they are a Liquid Body) do communicate to them such a force or impression as is sufficient so to affect our Eyes, as to produce the sense of Seeing.

The Sun therefore, and the rest of the fix'd Stars, shine with their own Light, which their brisk and lively Rays are an evident Proof of. And the reason why the Sun appears so great to us, in comparison of the fix'd Stars, is, because he is nearer to us, who are in the same Vortex. For which reason also, the Sun doth not only abundantly illuminate our Earth, whence he is called in Scripture, the Greater Light; but also communicates heat and warmth to the same: Whereas the fix'd Stars, tho' visible to us; because of their Remoteness can do neither.

The Sun therefore is no solid Body, neither a burning Stone, nor Red-hot Plate, as some of the Ancients apprehended, but consisting of a very fluid and movable Matter, which whirls all the Circumjacent parts of Heaven round with it. And thus much is not only confirm'd to us by Reason, but also by Astronomical Observations: For SIMON MARIUS, in Scheinerus his *Rosa Ursina*, tells us, That he had beheld the Sun thro' an Optick Glass, boiling like molten Gold in a Furnace. ATHANASIUS KIRCHERUS, in his Book entituled, *Ars magna Lucis & Umbræ*, writes, That he had seen the Sun, like to the Sea, tost and foaming with Waves. And RAPHAEL AVERSA assures us, That he had observ'd the Sun to be a Fluid Body, contain'd in its place, as if it were in a Vessel, and agitated within it self, like a molten Metal. Yea, there are several who have assured me, that the whole Body of the Sun boyls continually, and that they had often observ'd it through a Prospective-Glass, boiling like Water in a Kettle.

Whence all Modern Philosophers that are of any Note, take it for granted, that the Sun is nothing else but a Fire or Flame. Since we have great reason to conclude that Body, which gives forth Warmth and Light, to be Fire; but we Experience the Sun to give forth Heat and Light: Therefore we must conclude the Sun to be a Fire. The Minor is manifest, because we are convinced that both these proceed from the Sun by our Feeling and Sight; neither do we find any thing in the Fire, which we may not with equal right attribute to the Sun. Besides, we cannot conceive any Body to have an inborn or connatural Light, by means of which it produceth Heat, except it be of the nature of Fire. Wherefore, seeing the Sun is as communicative of Light and Warmth, as Fire is, and that both of them have the same Properties; for the Sun dries, melts, kindles, and burns, as well as Fire: Therefore we must conclude that the Sun is Fire. For we can have no stronger Argument to prove two things to be the same, than by demonstrating, that all the Effects of one of them, do also proceed from the other. For as if any one by Night should meet with a Body that sent forth flames, heated the Bodies that were near it, and enlighthned the Air, he would make no scruple to conclude it to be a Fiery Body: In like manner,

IV. Why the Sun is Lucid.

V. How it comes to pass, that the Sun appears so much greater to us than any of the fix'd Stars.

VI. The Sun is a Fluid Body.

VII. The Sun is a true Fire.

seeing the Sun performs all these things; we are not to question but that it is a Fire or Flame.

VIII. But against this you will object, First, if the Sun were a Flame, and as such continually diffus'd its heat through the whole World; it would follow from hence, that the Air would never be cold; but this is contrary to Experience: For we find the Air much hotter in Summer, than in Winter.

Some endeavour to solve this Objection, by saying, that the Difference of Heat we feel at divers Seasons, proceeds from the various incidence of the Sun-beams on the Surface of the Earth, which in Summer come down to the Earth more directly, and in Winter more obliquely or slantingly. But this Answer will scarcely satisfy those, who consider that the Surface of the Earth is not polish'd, as a Looking-Glass, but rough and very uneven; and that consequently it may receive direct Rays in Winter, as well as Summer. The reason therefore why the Cold is more intense about the Earth in the Winter season, is, because the Air we breathe in, which is ten or twelve Miles high, hath a very smooth and even Surface, as having no Winds to ruffle it; and the Sun-Rays falling very slantingly in the Winter upon this smooth Surface, is the reason why fewer Rays are transmitted to us in Winter, than in other Seasons of the Year. To which may be added, that more Vapours and Exhalations at that time proceed from the Earth and Sea, which filling the Air, do allay the Heat of the Sun.

IX. In the Second place, you'll object, That our Fire here below stands in need of Fuel, which is no sooner taken away, but it becomes extinct, and vanisheth. But in the Heaven there is no Fuel to feed the Sun's Flame. Therefore it is a great mistake to suppose it a Fire.

X. I Answer in the first place, That the state of the Sun, and our Flames here below, is very different: For our Flames stand in need of Nourishment, because they are compos'd of a Fluid and Moveable Matter, which is easily destroy'd by the Bodies that surround it; and therefore it is needful it should be furnish'd with New Matter, to supply that which is extinguish'd and vanisheth. But above the Sun there are no such Agents as are able to dissipate its Matter, and therefore it needs no Fuel to preserve it. For so vast a quantity of Fiery Matter is heap'd up in the Sun, that it can neither be exhausted or extinguish'd by it self, nor by the Heaven that surrounds it.

XI. I answer in the Second place, That the Matter of the First Element is the Fuel of the Sun's Flame, which is continually convey'd to the Sun, in the room of the like Matter, it loseth at any time. For the Stars entertain such a Communication among themselves, as to convey food to one another through their Vortexes, bestowing upon others what goes out by their Ecliptick, and receiving from others what comes in by their Poles. And thus New Matter continually enters into the Sun, by the Poles, and other Matter again flows out from it, in that part which is farthest from the Poles. And accordingly the Sun is always said to be the same, in like manner as a River is supposed the same, notwithstanding that New Matter con-

tinually makes up the defect of that which runs away.

The Sun is not only the Cause of the Light, which in the day time is diffus'd through the Air; but also of the Twilight, which is perceived in the East before its Rising, and in the West after its Setting; forasmuch as the Rays of the Sun falling obliquely upon the Vapours that are in the Air, are refracted towards the Earth. The Beginning of this Twilight happens, when the Sun is deprest beneath our Horizon, about 18 Degrees, perpendicularly taken from the Vertical Circle. Hence it is, that in those parts of the Earth where the Sun doth not in Summer sink below the Horizon 18 Degrees, there they have a continual Twilight all Night long.

Whatsoever part of the Earth the Sun salutes with his Rays, there he is said to Rise; and to Set in those Parts which he ceaseth to illuminate. Now forasmuch as there is no part of the Earth in which he may not sometimes Rise, and sometimes Set in this manner, we may assert, contrary to the Vulgar receiv'd Opinion, that there are no certain Points of the Sun's Rising or Setting.

XII. How the Sun makes Twilight.

XIII. There are no certain Points of the Sun's Rising and Setting.

CHAP. XV.

Of Light.

The Peripateticks generally are of Opinion, that Light is a Quality really distinct from Substance; and propagated to the Senses they don't know how. But this Opinion, at present, hath but few Followers: First, Because it is evident, that Qualities are no Entities really distinct from Substances, but only their Modifications; which neither can remove from the Substances wherein they are, nor do any thing without them.

Secondly, Because the Beams of Light are reflected from some Bodies: Now every Reflexion is caus'd by Resistance, and whatsoever meets with Resistance, must be Corporeal; but forasmuch as meer Qualities, abstracted from Substances, include nothing of Corporeity, neither can they be liable to Resistance. Whence we must conclude, that Light which is Reflected, is no pure Quality, separately existing from the Lucid Body.

Thirdly, The Rays of Light are refracted, and by the help of Convex-Glasses are strengthened; which could not be in case the Light were a meer Quality, for then, as being destitute of all Quantity, it would equally penetrate all Bodies. For the better understanding whereof, two things especially are to be supposed.

First, That all Bodies consider'd in themselves, strive to move in Right lines. For a Stone thrown from you always moves strait forwards towards some part or other; nor ever turns aside, except by other Bodies meeting with it, it be forced to rebound or deflect. Secondly, That whatsoever is Circularly moved, as far as it is able, strives to recede from the Center of its motion; as we may experience in a Leaden Bullet tied to a String, for we feel that the swifter the Bullet is whir'd about, the stiffer the String is extended and stretch'd; which cannot be attributed to any other Force, but because it strives to recede from the Center of its motion.

I. The Opinion of the Peripateticks, concerning Light, refuted.

II. Two things are to be supposed, in order to the understanding of the Nature of Light.

When

III. When I say, that the *Bullet* strives to withdraw from the *Center* of its *motion*, it is not so to be understood, as if the *Bullet* or any other *Body* had a perceptive inclination to move one way rather than another; but only that it hath such an impulse to *motion*, that it would move in such a manner, in case it were not hindered of something else.

IV. We assert therefore, that *Light* consists only in this, that the *Matter*, which is in the *Center* of every *Vortex*, by its swift *whirling* about, doth shake the *Luminous Matter*, that is dispers'd throughout the whole *Heaven*, and all *Diaphanous Bodies*, which in *Right lines* beating against the *Nervous Fibres* of the *Tunica Retina*, produceth that perception, whence *Bodies* are denominated *Lucid*: For as a *Blind man* by the means of his *Staff*, because of its *Resistance* only, is able to distinguish betwixt *Bodies*; tho' no *Species* be transmitted by the *Stick* to the *Eye*: So likewise the Cause of the Perception of *Light* is nothing else, but that a certain *Matter* dashing against the *Organs of Sight*, stirs up the *Soul* to such an *Animadversion*.

V. *Light* therefore is a *Quality* proceeding from the *Vibration* of the *Globuli diffus'd* in *Right lines*, and moving the *small fibres* of the *Optick Nerve*, dispers'd through the *Net-like Membran* of the *Eye*. Which is then chiefly, when the *Matter* of the *First Element*, contained in the *Center* of the *Sun*, or any other *Lucid Body*, strives to withdraw from it: For in so doing it presseth the adjacent *Globuli* of the *Second Element*, and they again those which are above them to the very last. So as that by this means the *Light* is diffused in a moment, to any distance whatsoever. Which will not be hard for us to conceive, if we consider that the *Action* of *Light* doth not so much consist in *Motion*, as in *Pression*, or a first disposition to *Motion*; and therefore that the *Rays* of *Light* are nothing else but so many *Lines*, by which that quick and lively *Action* is performed.

VI. From whence we conclude, that the *Sun* doth not more forceably drive forwards the *Matter* which is towards the *Ecliptick*, than that which is towards its *Poles*: For the *Sun* being of a *Round figure*, the *Matter* of the *First Element* entering into its *Center*, doth equally drive from it all the *Globuli* that surround it; so that no greater Force proceeds from one, than from any other *Point* of its *Superficies*, by which means infinite *Rays* are extended to every part of the *Body* it illuminates.

VII. To the Production therefore of *Light*, is required, *First*, *Matter* very swiftly agitated, as is that which is in the *Center* of every *Vortex*. *Secondly*, A certain *Matter* that is shaken, as is that *Matter* which is about the *Stars*, that is, the *Globuli*. *Thirdly*, It is requisite that this *Matter* be shaken or vibrated in *Right lines*, or such as are equipollent to *Right ones*: For tho' in all *Diaphanous Bodies*, the *Pores* are not *Mathematically* strait; yet are they sufficiently so, for the transmission of the *Action* of *Light*. *Fourthly*, That this *Vibration* of the *Matter* be such, that by Moving the *Nerves* the *Soul* may be excited to that perception we call *Sense*; for it is our *Soul*, and not the *Body* that is sensible. When therefore either the *Organ* is unfit to receive this *Vibration*,

or that it be affected by any stronger *Vibration*, the *Sensation* will be thereby hindered. And this is the reason, why after the *Sun* is risen we cannot see the *Stars*; because the stronger *Vibration* of the *Sun*, renders the weaker *Vibration* of the *Stars* imperceptible, except it be in case of some very great *Eclipse*.

Tho' the *Light* diffuse it self on every side, and equally drive before it the adjacent *Matter*; yet is its *Action* lessen'd according to the *Degrees* of its elongation from the *Luminous Body*. The better to comprehend this, suppose we the *Tube ABC* here decypher'd, enlarging it self by *degrees* to contain *Water* as high as *DE*; and let afterwards, by means of a *Spring*, so much *new Water* be spouted into it by the *Hole A*, as may be sufficient to fill the *Space AFG*, which tho' it be of some height, yet it hath but little breadth; it will hence appear, that by the accession of this *New Water*, the *Water* contained in the *Tube* will be sensibly raised a little higher towards *HI*, but not toward *DE*. By which *Example*, the Nature of *Light* is fitly illustrated: For as we cannot say, that the *Water* above *DE* is not raised higher at all, but only that it is raised very little; so in like manner we must say, that the farther the *Beams* of *Light* recede from the *Luminous Body*, the weaker and less their *motion* is.

As a *Body* that is in *motion* upon meeting with another *Body* that resists it, doth lose its determination, and is forced to turn aside; as we experience in a *Ball*, which being struck against a *Wall*, rebounds; so we are to conceive, that the *Light* meeting with some *hard Body*, is by it reverberated. For seeing that *Light* is nothing else but a *pression* of the *Globuli* of the *Second Element*, which tho' in the *Pores* of *Water*, *Air*, *Glass*, and other such like *Bodies*, do touch one another in various *ranks* or *rows*: Suppose the *Globuli* that constitute the *Row CD*, to represent those *Parts* of the *Second Element* that constitute one *Ray*, falling upon the *hard Body AB*; it is necessary that the *Action* of this *Ray*, be continued by the *Line DE*, towards *E*, that so the *Angle* of *Reflexion BDE*, may be equal to the *Angle* of *Incidence ADC*; that is, this *Action* must be transmitted by the very same *Lines*, which the *Globulus C* would describe, in case it were alone, and were moved by the *Line CD*: For it is manifest, that the *Globulus D* is disposed to move onwards that way it would really move, if its *Power* were reduced to act. And because this *Globulus*, by meeting with the *Body AB*, would neither tend towards *G* nor *H*, but only towards *F*, it is evident that the *Globulus F* only is push'd forwards by it, and that that alone receives its *Action*. This is confirm'd by daily Experience, for we find that the *Sun-beams* falling upon the *Surface* of any *Compact Body* (as *Gold*, or *Steel*) are reverberated, and that the *Light's* *Angle* of *Reflexion*, is equal to the *Angle* of *Incidence*.

I know no *Body* that hath better explained the nature of *Light* than our *Author*: And tho' they who maintain *Light* to be *Fire*, do support their Opinion by strong *Arguments*, yet they struggle with many difficulties, which are of no force against our *Opinion*. For according to their *Hypothesis* two *Bodies* would be in one place, if *Light* and *Fire* were one and the same thing. Again there

VIII. The farther the Beams of Light withdraw from the Luminous Body, the less and weaker they grow.

Figure 24.

IX. How tho Light must be reflected upon its meeting with some Bodies.

Figure 25.

X. Light cannot be Fire.

are many things that give *Light* without imparting *Heat*. Moreover, what shall we say becomes of the *Light*, when the *Sun* leaves our *Hemisphere*? shall we suppose that such a vast *Body* can perish in a moment? And lastly, how can the *Light* without interruption or disturbance reach our *Eyes*, when the *Air* is shaken by *Winds*, seeing one *Body* always resists another? And other such like difficulties that may be urged against the *Light's* being *Fire*.

IX. But by constituting the nature of *Light*, in the *Pression* of the *Subtil matter*, we are delivered from the Danger of *Penetration of Dimensions*: neither are we necessitated to admit that *Light*, is always in conjunction with *Heat*; forasmuch as the *matter* of the first *Element*, can withdraw from the *Center* of the *Lucid Body*, and push forwards the *Globuli* of the second, which compass it about without producing the effect of *Heat*, as appears in *Glow-worms* and *Rotten-wood*. Neither are we pinched by that Question which demands, what becomes of the *Light* when the *Sun* withdraws from our *Hemisphere*, seeing we maintain the *Light* to be no more than *motion*, which cannot but cease as soon as the cause vanisheth. Neither needs the objection of the *Air* tost with *Winds* to trouble us, forasmuch as the *Intervals*, which we conceive to be between the *Parts* of *Bodies*, are fill'd with the *Subtil matter*, and are always open for the *Globuli* of the second *Element*, so that nothing hinders the *Light* from coming to us in a *Right Line*.

XII. There is one difficulty only which seems somewhat to affect us, viz. how the *Light* of the *Sun*, and *fixt Stars* can reach our *Eyes* in a moment; yet even this also will be removed, if we consider, that the nature of *Light* doth not consist in the *Duration* of *Motion*, but that it is only a *Subitaneous Action*, directed to our *Eyes*, through the *Pores* of the *Air* and other *Diaphaneous Bodies*; much after the same manner, as we by night with a *Stick* can discern and distinguish between *Water*, *Clay*, *Stones* and such like: For we then experience that the same *Action*, wherewith the end of the *Stick* toucheth the *Body*, is at the same instant felt at the Head of the *Stick*: And which would be the same were the *Stick* never so long, as might be demonstrated by many Examples.

XIII. If it be objected, that the *matter* of the second *Element* being *Fluid*, a Range of its little *Pellets* reaching from the *Sun* to our *Eyes*, cannot have the same effect in pushing forwards in a *right Line* as a *Stick* would and must have; for the more round and slippery these *Pellets* are, the more apt they are to slide away, and by this means to make the impulsion of no effect. To this I answer, that tho' the *matter* of the second *Element* be the most *Fluid* of all *matters*, yet this doth not hinder but that a Rank of them, reaching from the *Sun* to our *Eyes*, may be as effectual in pushing, as an inflexible stiff *Line*: For the *World* being every where full, every Ray of *Light*, hath always many others about it, which hinder it from sliding away, and consequently transmits the *Action* of the *Lucid Body*, in the self same manner as if it were a stiff *Stick*.

XIV. You'll say, that no *Motion* can be made in an instant. We grant it, for in that *Motion* wherein the *Action* of *Light* consists, no *Body* is transmitted, but the *Motion* only is transferred from one

Body to another. For the *Sun*, who is the *Principle* and *Fountain* of *Light* is not transmitted to our *Eyes*, but its *motion* only is continued to our *Eyes*, by means of the *Subtil matter*, which fills the *Pores* of the *Air*, and other *Pellucid Bodies*. Nor is it any contradiction that a *motion* should be transmitted in an instant, tho' no *motion* can be made in an instant.

From what hath been said, it may be clearly understood, how that *Action*, wherein we conceive the nature of *Light* to consist, spreads and diffuseth it self every where from the *Body* of the *Sun* and *fixt Stars*, and how in the least moment of time it extends it self to the farthest distance; and to *Right Lines*, not only from the *Center* of the *Lucid Body*, but as well from any other *Points* of its *Surface*: Whence all other *Properties* of *Light* may be deduced. And I may add further, which will seem to some a great *Paradox*, that all these things would happen in the *Heavenly matter*, tho' there were no force at all in the *Sun* or any other *Star*, about which it was whirled: So that if the *Body* of the *Sun*, were nothing else but an empty *Space*, yet should we perceive his *Light* as well as now we do, (tho' it would not be so strong) at least in that *Circle* wherein the *Heavenly matter* is moved.

Some, it may be, will object that *Des Cartes* makes *Light* to be nothing else, but an *Aptitude to motion*; as when he saith *Dioptric. Cap. 1. that Light is nothing else, but the Action of the Celestial matter, or a Propension to motion*. Now if it be only a *Propension to motion*, it is no *motion*, and therefore the *Light*, which he saith, is received in the most *Subtil matter*, that fillsthe *Pores* of other *Bodies*, will never be produc'd, as long as it hath only a *Propension to push forwards* the same. Whence we must conclude, that if *Light* be an *Action*, and that such an one, as tends to the production of *motion*, *Light* must be before *motion*; for every cause is before its effect, and therefore *Light* cannot be *motion*.

This difficulty will be easily cleared, by distinguishing betwixt *Light* in its *Fountain* or *Principle*, such as are *Lucid Bodies*; and *Light* in a *Medium*, that is, any *Transparent Bodies*. The *Propension to motion*, or *pression* which is in the *Lucid Body*, as the *Fountain*, is properly called *Lux*: But when considered in its progress, that is, in the *Heaven*, or the *matter* of the second *Element*, then it is called *Lumen*, tho' *Authors* commonly confound both these words, using them promiscuously; *Lux* therefore, or *Light* in its *Fountain*, is a *Propension to motion*; or is that *Action* in *Lucid Bodies*, which tends to produce some *motion* in *Transparent Bodies*, which is *Lumen* or *Light* in a *Medium*. Neither doth it imply any absurdity to say, that *Light* in the *Fountain*, preceeds *Light* in the *Medium*, since every cause is before its effect. The *motion* therefore which is in *Lucid Bodies*, produceth another *motion*, that is, *Light* in the *Air*, and other *Pellucid Bodies*.

It may be you'll urge, that if *Light* be that *Action* or *Motion*, whereby the *Sun* or any other *Lucid Body* pusheth forwards the *Subtil matter*, which is in *Transparent Bodies*, then the *Sun* must be conceived to be before that *Action*, and by consequent would be destitute of all *Light*; every cause being before its effect.

is no Trans-
lation of a
Body.

um.

XVIII. The Sun is
not before
the Light.

But

X.
The Answer

But I answer, that this doth not follow, because the *Light* it self, or that *motion*, whereby the *Sun* doth circularly push forwards the *Subtil matter* whereof it is composed, is natural to it, and therefore it is not necessary, that as an *Efficient cause* it should be before it. Forasmuch therefore as the *Sun* is composed of the most *Fluid matter*, which is wholly whirled about its *Center*, it is necessary according to the *Rules of motion*, that it press the *matter* of which the *Heaven* is made, that is, the *Subtil matter*, which from the *Stars*, reacheth to our *Eyes*; in which *Action*, the nature of *Light* consists.

CHAP. XVI.

How Spots come to be Generated about the Sun, and fixt Stars, and how they vanish again.

I.
What the Spots of the Sun are and who was the first discoverer of them.

BY the *Spots* of the *Sun*, we understand those close or compact *Bodies*, consisting of gross and flow *Particles*, mixt with others that are more *Thin* and *Subtil*, which since they cannot comply with the *motion* of a more *Subtil matter*, are cast out from it; and by reason of their slower *motion*, clinging together about the *Surface* of the *Sun*, continue there for some time, and follow the *Sun's motion*, according to the course of the *Ecliptick*, till by the *Sun's* force they be dissolved, or sucked in again by it, or wholly expell'd from it. The first Observer and Discoverer of these *Spots* was *GALILÆUS*, in the year 1610, when he was *Mathematick Professor* in the University of *Paduā*; and asserted them to be contiguous to the *Body* of the *Sun*, and that they moved round it, or rather were whirled about by the *Solar Globe* in the Space of 26 or 27 Days.

II.
The Colour and Figure of the Solar Spots.

The *Spots* of the *Sun* appear for the most part of a *Black-colour*, and are commonly surrounded with a *Darkish cloud*, which in the inside is more *Bright* than it appears on the outside. They vary their *Figures*; as appears by that *Spot* which was first discovered by the Famous *CASSINUS* in 1672, and which appeared 36 or 37 Days. These *Spots* are moved more slowly from the *Eastern part* of the *Sun*, to the *West*, and pass from one brim to the other in about 13 Days time. Their *motion* is found to be more swift near the *Center*; and they seem to make as great way in that part in 4 Days, as they do in 9 or 10 Days when they are near the *Circumference*. They appear likewise bigger in the *Center*, but near the *Circumference* long and narrow. From this their swifter *motion* near the *Center*, it is concluded either that they cling to the *Sun*, or at least are very near to him.

III.
How these Spots are formed.

Now as to the manner of their *Formation* we are to note, that the *Particles* of the first *Element* are not all of them of the same *Bigness* and *Figure*; and tho' we conceive them to be very *Little*, yet withal we must conclude some of them to be cornerd, and not so fit for *motion*, if we consider the Spaces or Intervals of the *Globuli* through which they pass: For these Spaces being mostly *Triangular*, they by passing through them get the same *Figure*, not much unlike the form of a *Screw*, as hath been before observed: By which means it is, that they cannot move so swiftly as

before, but do as it were rest or lye still, with respect to others that are more swiftly moved, and so more easily cling together. For tho' they retain the name of the first *Element*, as long as they continue between the *Globuli* of the second *Element*, because then being yet in their swift course, they only fill up the Spaces that are betwixt the *Globuli*, without composing any grosser *Bodies*: Yet they obtain the name of the third *Element*, when they come near to the *Body* of the *Sun*, especially the more gross and slowly moved *Particles*; for seeing they cannot comply with the *motion* of the rest of the subtil Matter of the first *Element*, they are cast out from it, and by running together into great Lumps or masses, they obscure and at last wholly hide the *Star*, from whence they came forth; for by clinging to its *Surface*, they darken and obstruct the *Light* proceeding from it, and hinder it from pushing forwards the subtil Matter in right *Lines*, wherein the force of *Light* doth consist.

Some *Spots* are more *Solid*, and very compact, as are those which run round the *Sun*; others are more *thin*, and therefore dissipable, such as are those which sometimes appear about the *Sun*, and then vanish again.

For as we see that *Water* or *Oil* boiling in a pot, doth cast off those *Particles* that are less fit for *motion*, and raise them up to the *Surface*, reducing them into *Scum*: So the *Sun*, whose matter is agitated with a fervent *Heat*, doth cast off from it, those grosser and many corner'd *Particles*, which cannot accommodate themselves to the motions of others, and these afterwards running together, constitute a kind of *Scum*, and so obstruct the *Light*. Which then more especially happens, when the *Sun* darts his *Rays* more forceably against them, for by this means, they are driven more closely together, and become more compact.

By this means it may happen, that a *Spot* which at first is *Soft* and very thin, may at last grow to that hardness, as to stop the passage of the *Sun's Rays*. Thus *Historians* assure us, that the *Sun* hath been seen for many days together of a *Pale colour*, not much exceeding the weak and dim *Light* of the *Moon*. Neither, in my Judgment, is there any other reason assignable, why some *Stars* appear now greater, and at other times less, but because their *Aspect* is varied, according to the diversity of *Spots* that surround them: Yea, they may sometimes become so totally cover'd by them, that for many years they may be hid from us. So formerly the *Constellation* of the *Pleiades* consisted of 7 *Stars*, whereas now 6 only can be seen.

And on the contrary it sometimes happens, that a *Star* not seen before, all on a sudden appears to the *World*: Which is when the *Vortex* wherein the *Spot* is, by pressing the Neighbouring *Vortexes* more strongly, than they press it, doth enlarge its Bounds; by which means the *Matter* of the first *Element*, rushing in more abundantly, to the obscured *Star*, diffuseth it self over the *Surface* of the *Spot*; as *Water* is seen sometimes to overflow the *Ice*: and then the *Star* shines forth as *Bright* as if it had no *Spot* at all to darken it. According to this *Hypothesis*, we may understand how the *New Star* came to appear in *Cassiopeia* in the year 1572, which continued for 2 years, but

IV.
Spots are of two sorts

V.
Spots like a kind of Scum, stick to the Star whence they proceed.

VI.
The Sun appears sometimes more dim and obscure because of the interposition of his Spots.

VII.
How a new Star may suddenly appear.

appeared greatest at first, and afterwards being darkned by Degrees, at last wholly vanished.

VIII.
How these
Spots are
sometimes
turned into
Torches.

It also happens sometimes, that the *solar Matter* flowing about the *Spots* wherewith it is covered, doth rise above or beyond them, which *Matter* being thus pent up between them, and the *Surface* of the Neighbouring *Heaven*, is made to move more swiftly; as a *River* that is straitned in its passage doth run with more violence. And for this reason it is, that often *Torches* or *bright Flames* have been seen where formerly *Spots* appeared; and so on the contrary, the parts of *Spots* beginning to appear again, *Spots* have been seen where formerly *Torches* appeared.

IX.
Why the
Spots about
the Sun
move so
slowly.

The *Spots* about the *Sun*, take up no less time than 26 Days in running round it, notwithstanding they are so near to the *Body* of it; which slowness of their motion proceeds chiefly from hence, that a kind of *Aether* is generated, of the *Striate Matter* which the *Sun* continually casts forth, which extending it self a great way towards the *Orb* of *Mercury*, doth hinder the motion of the *Maculae*.

X.
The Cause
of the
Darkness
which hap-
ned at the
Death of
Christ.

It doth not appear by *Authors*, whether the whole *Earth* was darkned at the Death of *Christ*, or the *Holy Land* only: But supposing (as it is most probable) that the whole *Earth* was obscured (as the *Scripture* seems to assert, and *Dionysius* the *Areopagite* does plainly witness, who was a Spectator of this wonderful *Eclipse* at *Heliopolis* in *Egypt*) the cause of this Obscuration can't be attributed to any thing better than to these *Spots*. Seeing it is possible for one *Spot* to spread it self over the whole *Surface* of the *Sun*, and to continue there for some time, before it be dispers'd again. And forasmuch as the *Body* of the *Moon* is much less than that of the *Sun*, we must conclude, that this total Obscuration could not proceed from the *Moon* alone, without the assistance of these *Solar Maculae*, or *Spots*.

XI.
The Moon
assisted in
the obscu-
ration of
the Sun,
at our
Saviour's
Death.

I will not deny, but this famous *Eclipse* might be caused by the intervention of the *Moons Body*, notwithstanding that it hapned at the time of the *Full Moon*. It appeared so to *St. DENTS*, as he testifies in his *Epistle* to *Polycarpus*: *Whilst I was* (saith he) *at Heliopolis in Egypt, I beyond all expectation saw the Moon upon the Body of the Sun*. Whereupon, as being astonished at this *Prodigy*, he cried out, *Either the God of Nature suffers, or the Frame of this World is dissolving*. But then, because the *Body* of the *Moon* was not great enough to effect a total obscuration, the *Solar Spots* came to its assistance, and wholly cover'd the *Sun* for three Hours together.

XII.
How these
Spots come
to disap-
pear again.

As these *Spots* are generated, so in like manner are they dissolved again and vanish. For as *Oil* and other *Liquors*, do after some time suck into themselves again the *Scum* that hath cover'd their *Surface*; so likewise the *Striate Particles*, that cover the *face* of the *Sun*, in process of time grow less; and as they at first came from it, so they return to the *Sun* again. Except the thickness of the *Parts*, into which they are resolv'd, be such, that they are not able to pass through the *Globuli*, that are near the *Sun*; and therefore are forc'd to wander about, and disperse themselves in the adjacent *Heaven*.

CHAP. XVII.

Concerning COMETS.

COMETS are certain Bodies appearing amongst the *Stars*, in the utmost part of our *Heaven*, and that in various *Forms*, and in bigness resembling *Mars*, *Jupiter*, or *Saturn*, when they are cover'd with a *Mist* or little *Cloud*. They are compos'd of the *Parts* of the *Third Element*, and are so solid, that after they have for some time been swiftly carried in our *Heaven*, they are cast off into some of the Neighbouring *Vortexes* of the *Second Heaven*, and so disappear to us. They are sometimes called *Hairy Stars*, because of *Beams* like *Hair* proceeding from them, by which they are distinguish'd from the *Planets*, which appear exactly Round.

I.
The Nature
of Comets.

The *Comets* therefore agree with the *Planets*, in that both *Planets* and *Comets* are Vast, Round, Opake Bodies, flowing or swimming in the *Heaven*. And they differ, in that *Planets* are less solid than *Comets*, and therefore not capable of so great agitation; as whereby they may be driven out of the *Sun's Vortex*, into other Neighbouring *Vortexes*; as *Comets* which have a stronger impulse, by reason of their greater solidity, do continually pass out of one *Vortex* into another.

II.
How Co-
mets agree
with, and
differ from
Planets.

The *Peripaticks* rank *Comets* amongst *Fiery Meteors*, and therefore attribute their Generation to *Exhalations* arising from the *Earth*, and kindled in the upper *Region* of the *Air*; but the *Modern Philosophers* are of a different Opinion, and that for these following Reasons.

III.
The Peripa-
ticks sup-
pose Comets
to consist of
Earthly
Exhalations.

First, Because *Comets* are in the *Heaven*, and not in the *Air*, as being observ'd to have either no *Parallax* at all, or a very small one, that is, less than the *Moon*, and consequently must be at a greater distance from us than she is: For the lesser the *Parallax* of any *Star* is, the greater is the Distance.

IV.
Reasons
against the
foresaid
Opinion.

Secondly, *Comets* cannot consist of *Earthly Exhalations*, because they are bigger than the *Earth* it self: For their appearing *Diameter* (their Distance consider'd) is oftentimes greater than the *Diameter* of any of the *Planets*. The appearing *Diameter* is different, according to the Distance of the *Body*, as being Smaller in a less Distance, and Greater in a greater Distance.

Thirdly, If *Comets* were kindled *Exhalations*, no reason could be given why they should not decrease daily, as their *fuel* decreaseth; whereas we find that they all increase and decrease after one and the same manner: For they are less at the Beginning and End of their appearing, and biggest in the Midst. But because some relate, that *Sublunary Comets* have at some times appeared, we will distinguish *Comets* into *Bastard* and *True*.

We call those *Bastard Comets*, which are compos'd of *Earthly Exhalations*, raised into the upper *Region* of the *Air*, and there kindled. But *True Comets* are such as are above the *Moon*, and which shine by reflecting of the *Sun's Beams*, not by being kindled into a *Flame*. Those of the first kind, if any such be, are *Meteors*; but the latter are all *wandering Stars*.

V.
The distin-
ction of
Bastard
and true
Comets.

A *Comet* therefore is a *Wandering Star*, compos'd of the *Matter* of the *Third Element*, which because of its solidity and great agitation passeth

XI.
The Place
of the Co

from one Vortex to another. I take both Comets and Planets to be perpetual Bodies, made in the Beginning of the World, and continually tost between the Superiour or utmost parts of the Vortexes.

VII.
The Original of Comets.

But to the end we may the better understand the Original of Comets (in case we should suppose any of them to be produc'd anew) we are to remember, that the Matter of the First Element, which from other adjacent Vortexes, passeth thro' the Poles into the Center of our Vortex, doth carry along with it many striate Particles, which being unfit to comply with the swift agitation of the subtil Matter, are cast forth; which afterwards, because of the inequality of their Figures easily cling and stick fast together, and by this means come to constitute great Masses, and being close to the Star from whence they proceed, resist the Action, wherein the Nature of Light consists; and in this respect, are very like those Spots about the Sun, which we have already spoken of.

VIII.
How a fix'd Star becomes changed into a Comet.

Now, whenever it happens that a Star is cover'd with so many and thick Spots, as that its Vortex becomes swallow'd up of other adjacent Vortexes: Then if it be so solid, that before it comes to that Term or Limit, where the parts of the Vortex are most slowly moved, it happens to acquire a motion equal to that of those Parts amongst which it is, in this case it descends no lower, but from this Vortex passeth into others, and becomes a Comet. But if it be less solid, and consequently descends beneath that Bound, then it continues there at a certain distance from the Star, which is in the Center of that Vortex, and whirls round about it, and by this means becomes a Planet. For this is the difference betwixt a Comet and a Planet, that a Comet being more solid, is carried from one Vortex into another; whereas a Planet continues fix'd to one Vortex, and is obsequious to its motion.

IX.
The Air is not the Place of Comets.

Tho' Modern Authors be much of the same mind with one another about the Substance of Comets; yet are they at great Variance about the Place of them. Some will have them generated in the Third Region of the Air, as being of Opinion, that the Exhalations, of which they suppose Comets are made, cannot ascend higher. But this Opinion, as hath already been made out, is not probable; forasmuch as the same Comet, is at the same time perceived, in divers very remote Parts of the World, especially that of the Year 1618, which was seen in Europe, and in the East-Indies, which could not have been, had its place been in the Air.

X.
They run round the Earth in 24 Hours.

Besides, Comets commonly compass the whole Earth in 24 Hours time, and are observ'd to make the same stay above, as under the Horizon. All which may easily convince us, that they must be above the Air. For the Earth is not far distant from the Circle of the Air, and compar'd with it, hath a considerable Magnitude; so that if from its Surface we should divide the Air into two Halves, they would not be equal, but the Half hid from our sight, would far exceed the other; and accordingly a Comet would longer continue under, than above the Horizon; which we find not to be so.

XI.
The Place of the Co-

Comets therefore are to be placed in that Space, which is between Saturn and the fix'd Stars; as

appears by their Excursions, and other of their Appearances. Neither can they be placed amongst the Planets, forasmuch as they are Regular in their Motion about the Sun, and never wander out of their Spheres. And by this means we may easily apprehend, how Comets absolve their Revolution in 24 Hours time, and continue no longer under, than above our Horizon; because the Bigness of the Earth being inconsiderable, with respect to that Space they move in, we may well enough divide the Circle of the Air into two equal Halves.

And tho' Tycho, and other Astronomers, who have accurately observ'd their Appearances, have only said, that they were above the Moon, towards the Spheres of Venus or Mercury, and not above Saturn, (tho' they might as well have concluded, that from their Calculations;) the Reason whereof was, because they disputed against the Ancients, who took the Comets to be Meteors, and therefore were content to shew that they were in the Heavens, and were loath to attribute to them all the height, which they had found out by their Calculations, lest they should be disbelieved, by advancing such incredible Paradoxes.

But forasmuch as the Space which is between Saturn and the fix'd Stars, is Immense; we say that Comets, how great soever they may be, cannot be seen by us, if they be far distant from our Heaven; for the Light which they borrow from the Sun is very weak, neither have they force enough, at such a distance, to affect our Sight. Which is the Reason, that when they approach to the fix'd Stars, they disappear; or if their Body appear, yet their Tail is hid. But the fix'd Stars, which are beyond them, easily transmit their Light to us, because they have a Light of their own, which makes them dart their Rays more strongly; whereas Comets that shine only with a borrowed Light, must be in our Heaven, to be seen by us.

The Comets do all of them seem to move about the Earth from East to West, and in this their Motion they describe Circles almost parallel to the Equator. But besides this apparent Motion, which is common with them to all the rest of the Stars, they have another that is peculiar and proper to themselves, but very irregular and indeterminate, by which some of them move from East to West, others from West to East, or to other Coasts of the Heavens. Neither can their Course be said to be Regular, but rather various and unequal, since some of them pass through a greater Space of Heaven than others. But however Great this Space may be, there are but few of them that ever were perceived to run through above one Half of the Heaven.

When a Comet casts its Rays towards that part of the Heaven, whither it is carried by its own Motion, such Rays are commonly called a Beard; but when they tend to that part from whence it tends, then are they called the Comets Tail; and when they are cast forth circularly, we call them Hair, or a Rose.

It will not be difficult to give a Reason of these Phenomena, if we call to mind that the Heavenly Globuli of the Vortex wherein we live, are by so much less, as they draw nearer to the Center, and by degrees grow greater and greater until the

Comets is between Saturn and the fix'd Stars.

XII.
Why some Astronomers say, that Comets are only above the Moon.

XIII.
Comets that wander out of our Heaven, are no longer seen by us.

XIV.
How the Comets are moved.

XV.
What the Beard, Tail, and Hair of Comets is.

XVI.
The Cause of these Appearances.

Sphere

Sphere of Saturn, where they are of an equal bigness, and are more swiftly moved. When therefore a Comet, taking its Course beyond the Region of Saturn, transmits the Rays it receives from the Sun to us, it at the same time pushes forwards the Globuli of the Second Element in Right lines to our Eyes, which imparting their active Force to others that are under them, produce an entire and pure Light, which makes the Head or Body of the Comet to appear to us: Whereas those which fall obliquely upon the little Globuli that are beneath, or on the sides of them, are partly refracted, and so represent a Beard or Tail to us. But those which are dispers'd round about on all sides, exhibit Hair, or a Rose. For the variety of all these Appearances proceeds only from the Reflexion of the Rays of Light upon the Comet; which having been refracted by passing through the Heavenly Globuli, are so received into our Eyes, as if they came from those parts, where we think we perceive the Beard, Hair, or Tail of the Comet.

Figure
26.

Thus the Globuli of the Second Element, 3, 2, 1, 9, 7, which are extended from the Sun to the utmost Bound of the Sphere of Saturn H, C, I, are very small, whereas those that go beyond that Sphere H, F, A, 4, 5, 6, I, do exceed them in Bigness; so that each of the greater Globuli, that are in the utmost part of the Sphere of Saturn, may be surrounded by 7 or 8 of the smaller Globuli that are lower. And forasmuch as the greater Globuli, falling perpendicularly upon the Sphere of Saturn, do push upon few of those that are under them, they must necessarily produce only a weak Refraction of Light; whereas on the contrary, those that fall obliquely upon it, since they have many little ones on one side of them, must needs make a greater Refraction of weak Rays. As for Example; the Greater Globulus C, falling perpendicularly on the little ones that are under it, hath only 2 Globuli, viz. 1 and 3 on each side, and therefore both ways produceth small Refractions, deflecting from the Perpendicular C B, whereof the one is only directed from C to D, but the other from C to E: But the greater Globuli H and I, falling obliquely on the lesser, do push forwards 6 or 7 of them, viz. those that lye under them; and therefore the greater Globulus I, produceth a considerable Refraction from I unto B, deflecting from the Perpendicular I K; and so likewise the great Globulus H, makes a great Refraction from H, to B, deflecting from the Perpendicular H G.

XVII.

How Comets come to appear with Tails, Hair, and like Beams.

Figure
27.

Hence it appears how Comets come to appear with Tails, Hair, or like Beams. For let us suppose the Sun to be S, and the Sphere through which the Earth is supposed to be carried in 24 Hours time, to be 2, 3, 4, 5; the Term from whence the Heavenly Globuli begin to grow less and less by degrees till they reach the Sun, to be D, E, F, G, H, and C, to be the Comet plac'd in our Heaven; it is manifest that the Rays of the Sun are not only reflected from the Comet in the Right lines C F 3, C H 6, C G 4, C E 2, and C D 7; but that they are also refracted side-ways, and dispers'd; so that according to the various Position 2, 3, 4, 5, of the Spectator upon the Globe of the Earth, the Comet seems either to have a Tail, as in 2 and 4; for

by means of the direct Rays C, G 4, or C, E, 2, the Body or the Head of the Comet appears to us, and by the help of the refracted and weaker Rays, its Tail or Hair is discovered by us: Or with Hair, as in 3; for its Head is seen by us, by means of the strong and direct Rays C, F, 3; and by the Refracted and weaker on one side of it, C, G, 3, and on the other C, E, 3, we see the Hair of the Comet: Or nothing but its Tail is seen by us in the form of a fiery Beam, as in that part of the Sphere of the Earth 5, by means only of the weaker and refracted Rays C, D, 2, 5, or C, H, 4, 5; because no other Rays can reach the Eye of the Beholder, as long as he is posited in that part of the Terrestrial Orb, marked 5.

And from what hath been laid down, a Reason may be also given of all the other Phenomena of Comets. As,

First, Why they appear rarely, and not at set times or seasons.

Secondly, Why they do not move long in our sight.

Thirdly, Why they seem to be less at the Beginning, greatest in the Midst of their Course, and afterwards grow less and less by degrees. Which happens, because at first they are further from us; in the middle of their Course, nearer, and in a fitter condition to reflect their Rays; and towards the end of their Course, again more remote from us.

Fourthly, Why their Motion at the beginning is slower, in the middle swifter, and at the end slowest of all. The Cause whereof is, because the Comet at its first ingress meets with some Resistance, because of the Renitency of the Vortex, from whose Force it afterwards receives power to move more swiftly; and towards the end of its Course it is resisted by the Neighbouring Heaven, towards which it tends.

If any demand, why no Hair appears about Jupiter and Saturn, as well as about the Comets? I answer, That sometime there is a kind of appearance of short Hair seen about them, in that part which is opposite to the Sun, in places where the Air is very pure and clear. Wherefore, when ARISTOTLE saith, Lib. 10. Meteorologic. cap. 6. that the fix'd Stars have sometimes been seen, with Rays in the manner of Hair about them, I suppose it ought rather to be understood concerning these Planets. But as to that which he relates of the Hair, that appeared about one of the Stars in the Thigh of the Great Dog, it must have proceeded either from some very oblique Refraction in the Air, or rather from some fault or defect in his Eyes: For he adds, That it was less conspicuous when he fix'd his Eyes strongly upon it, than when he beheld it more remissly, and without any earnest intention.

CHAP. XVIII.

Of the Nature, Original, and Affections of Planets.

THE Planets are Various, Round, and Opaque Bodies, hanging in the Vortex of the Sun, and by it carried about the Sun, as a kind of a common Center of their Motions, receiving its Light, and variously conveying the same to our Eyes.

XVIII.
A Reason given of the various Appearances of Comets.

XX.
Why no Hair appears about Saturn.

I.
What the Planets are.

Eyes. That they are solid and opaque Bodies *GALILÆUS* shews, who by the help of his Tube hath discover'd no less inequalities in the Moon, than we meet with in our Earth.

II. There be Seven of them, which are counted in this order; Saturn, Jupiter, Mars, the Earth, the Moon, Venus and Mercury.

III. The SUN is commonly counted to be one of the Planets, but by a mistake; for besides that the Sun is not an Opaque, but a Lucid Body, nor hanging in another Vortex, but having its own proper Vortex; neither hath it likewise a wandering Motion, like the Planets, but is continually turn'd round in its own Vortex; and therefore cannot be reckon'd amongst the Planets.

IV. The Planets were formed of the Particles of the Third Element, from the running together whereof they became great Bodies. For no sooner was Motion communicated to the several Parts of the World, but the most subtil Parts (made so by their rubbing against one another) constituted the Sun and fix'd Stars; the Round parts (which Roundness they obtain'd also by their running against each other) made the Heavens; and the thicker and grosser Parts, being by reason of the inequality of their Figure, less fit for motion, formed the Seven Planets; *♄* Saturn, *♃* Jupiter, *♂* Mars, *♁* the Earth, *♁* the Moon, *♀* Venus, and *☿* Mercury. So that the whole Matter of this visible World may aptly be divided into three General Heads of Bodies, viz. such as send forth Light, as the Sun and fix'd Stars; such as transmit Light, as the Heavens; and such as Reflect the Light, as the Earth, with the rest of the Planets.

V. For the Planets being destitute of all Light of their own, shine only with borrowed Rays; and accordingly we find them only to be resplendent on that side which faceth the Sun; whence we conclude, that they only reflect to our Eyes the Rays they receive from the Sun. This we experience in the Earth, Mercury and Venus, and all the Secondary Planets, which in Eclipses are either wholly or in part obscured, when they come within the Shadows of other Planets; and being out of the reach of them, do only spread a Conical shadow from their opposite part to the Sun. And we may believe the same of Mars, Jupiter and Saturn; which by how much nearer they are to the Sun, the greater Light do they cast; and so much the weaker, as their distance is farther from it. The same is also manifest from hence, because the Light of all the Planets is more dim, than that which is seen in the Sun and fix'd Stars; as likewise, because there is not so vast a distance between them and the Sun, but that he can communicate his Light to them.

VI. And we are to suppose the same of this Earth we inhabit, which being made up of Opaque Bodies, does as strongly reflect the Sun's Rays, as the Moon doth. It is also surrounded with Clouds, which tho' they be less Opaque than many other Parts, and therefore do not so strongly reverberate the Light; yet we sometimes see them cover'd with as bright a Whiteness, as the Moon itself exhibits to us, when she is illustrated by the Sun. The same is also confirm'd, for that when the Moon intervenes between the Sun and the Earth, we see that its Face doth reflect a kind of obscure Light, which, as far as we can guess, must proceed

from the Earth, which reflects the Beams it receives from the Sun to the Moon. Which obscure Light sensibly decreaseth, as the illuminated part of the Earth turns away from it.

Tho' it cannot be doubted, but that the Planets are Spherical Bodies, like the Earth (for if they were of a plain figure, they would in one and the same moment be totally enlightned;) yet are they not so perfectly Round, but that their surface is very rough and uneven. For we find by the help of Telescopes, that they abound with Cavities and Eminences, corresponding to our highest Hills and deepest Valleys, (as *GALILÆUS* tells us concerning the Moon, *System. Cosm. Dial. prim.*) many whereof are continued for a Tract of an hundred Miles together; others again are single and compriz'd in one Heap. There appear also many steep and solitary Rocks. But the most frequent things to be seen there, are a kind of Bulworks (I call them so, because no fitter word occurs) of considerable Height, which encompass Spaces of different magnitude and figure, the most frequent being Circular. Many whereof have in the midst of them an high Mountain, and others seem to be filled with an obscure Matter, like those great Spots, which we may perceive in the Moon. From all which Particulars we conclude, that the Moon and the rest of the Planets, are altogether like our Earth, which if a Man could behold from the Moon, would appear much as the Moon shews to us, who view it from the Earth.

We are in the next place to consider how the Planets came to be, and what is the cause of their different Distance from the Sun, and from themselves. This will be the more easily cleared, if we consider, that the Planets are less solid than the Comets, and therefore are not tost from one Vortex to another, but continue in that of the Sun; as small Boats are driven about in a Whirlpool, or carried along with the Stream of a River. Whence we may apprehend, that the Planets, as soon as they were got into the Sun's Vortex, began to sink down towards the Center, till they met with those Celestial Globuli, whose motion was proportion'd with theirs. For seeing that the greater Globuli are more vehemently agitated, and withdraw themselves farther from the Center of their Vortex, it could not be, but that by their pushing against the Planets that are less solid, they must drive them towards the Midst; and when the Planets were sunk so low, that they met with those Globuli that were inferiour to them in bigness and force of motion, they run back from the Center, till arriving to that place of the Vortex where they were in equal poise, they neither came nearer to the Sun, nor went farther from it; but hanging there equally poised between those Heavenly Globuli, whirl'd continually about the Sun.

Wherefore we may imagin, that in that Space where we place the great Vortex of our Heaven, there were at the Beginning 14 or more Vortexes, the less whereof, and such as were weakned by reason of their Spots, were swallowed up of the Greater; which at last, together with the Lesser, fell into one common Vortex, viz. that of the Sun. So that the Stars, which in the Centers of the four smaller Vortexes, encompass'd Jupiter, betook themselves to that Planet; and those which were in the Centers of other Vortexes near to Saturn,

VII.
The Planets are not perfectly Round.

VIII.
The Planets are not so solid as Comets.

IX.
Of the first Production of Planets.

tended towards *Saturn*; as *Mercury*, *Venus*, the *Earth* and *Mars* tended towards the *Sun*. So that of so many *Stars*, all shining with their own light, the *Sun* only remained, whilst all the rest being covered with *Spots*, did not send forth light, but only reflect it.

X. It appears from what hath been said, why the *Planets* do not equally recede from the *Center*, and at different distances are carried about the *Sun*; this being to be imputed to their different solidity. For the *Globe* of *Mercury*, by Example, is nearer to the *Sun* than that of *Venus*, and the *Globe* of the *Earth* nearer than that of *Mars*, for no other reason but because they are less solid.

XI. Now Solidity is nothing else, but the proper Quantity of a *Body* compared with its Bulk and Surface; which is not only estimated from the Closeness and Thickness of its parts, but also by its Figure, and especially from the less extent of its Surface. For *Bodies* of a less Surface, do more easily pierce other *Bodies*: and therefore the greater the quantity of matter is, under a less Bulk and Surface, the more solid that *Body* is. As appears in *Gold* and other *Metals*, which when once put in motion, have a greater force to continue the same, than more lax and open, or porous *Bodies* (as *Wood* and *Stone*.) of the same Bigness and Figure; and therefore are esteemed more solid, that is, to have in them more matter of the Third Element, and less Pores filled with the First and Second Element. And this is the reason why *Mars*, tho' less than the *Earth*, yet is farther from the *Sun* than it, even because of its greater solidity.

XII. The *Planets* therefore, as hath been said, according to their greater or lesser Solidity, are farther from, or nearer to the *Sun*. By reason of this greater Solidity, *Saturn* is most remote from the *Sun*, whose Motion, if it had been swifter, and his Solidity greater, he would have been forced out of his Vortex, and become a *Comet*. Next to *Saturn* is *Jupiter*, with his four Secondary *Planets*, which we suppose did fall down into his Neighbourhood, before that Vortex, whose Center *Jupiter* was, had been swallowed up by the great Vortex of our *Heaven*. After him follows *Mars*, who, because of the extension of his *Body*, that is, his Magnitude and Figure, is more solid than the *Earth*. Next to him is the *Earth*, surrounded with its own Vortex, about which the *Moon* is whirled in a Months time. For the *Moon* tending towards the *Earth* (as the *Jovial Planets* towards that Planet) was swallowed up of its Vortex. *Venus* is nearer the *Sun* than either the *Earth* or the *Moon*, but the nearest of all is *Mercury*, as being the most solid of them all.

XIII. The *Planets* are divided into *Primary* and *Secondary*. *Primary Planets* are those that perform their Periodical motion only about the *Sun*, and not about any other Planet. *Secondary*, are such as are joined with another Planet, and together with it are carried about the *Sun*. Thus the *Moon* is a *Secondary Planet* with regard to the *Earth*, the *Jovial Stars* with regard to *Jupiter*; and so are those other Stars that attend upon *Saturn*. By the *Astronomers* they are commonly called *Satellites*, or *Guards* of those *Planets* to which they belong.

C H A P. XIX.

Concerning the Principle of the Planets Motion, and of their Direction, Station and Retrogradation.

Seeing that the *Heavens* are Fluid, and that the *Planets* do, as it were, swim in their Orbs, as in so many *Rivers*, it may be enquired what is the Principle of their Motions; as likewise what the cause is of those wandering excursions, whence the name of *Wandering Stars* hath been given them. Which name, we may believe, was there fore attributed to them; for that being carried about in the *Sun's Vortex*, they seem sometimes to approach nearer to, and sometimes to remove farther from one another; sometimes to ascend, and at other times to descend; sometimes to come nearer to the *Sun*, and at other times to withdraw at a greater distance from him. Whence arise the Conjunctions and Oppositions of the *Planets*, as likewise their Aberrations in Longitude and Latitude, so often inculcated by *Astronomers*. For tho' the *Planets* turn round about the *Sun*, yet do not they keep on their Course in the same direct Line, but do sometimes ascend, and at other times descend, as we see *wooden Bowls* do that swim in a *River*. And this their Deflexion is called *Aberration* in Latitude. Or else they are sometimes nearer the *Sun*, and sometimes farther from him; which are called *Aberrations* in Longitude. And this is the Reason, I say, why the *Planets* are call'd *Wandering Stars*, because they seem to roam at random, without keeping a steady course.

This wandering motion of *Planets* may be attributed to several Causes. As First, to the Figure of those Spaces wherein they move; for these, not being perfectly Round, but spreading more in Length than Breadth, it must needs be that the *Heavenly Matter*, that carries them, must move more swiftly, where it is narrowly pent up, than where it hath a broader space to move in. As we see that the *Wind* blows with less force in an open Field, than where it is straitned in a narrow Passage; and as a *River* runs more swiftly where it is straitned in its course, than where the Channel is wider.

In the second place, for as much as these Spaces do touch one another, the matter of the First Element, passing from one space to another, doth accordingly to the different degree of its motion, variously push forwards, and determine the Globuli of the Second Element, to drive the *Planets* more towards one part of *Heaven* than another. For the matter of the First Element being more swiftly moved, than the Globuli of the Second, it cannot but by pushing them forwards, move the *Planets* that are poised in the midst of them.

Thirdly, This difference in the motion of *Planets*, sometimes ariseth from themselves, as when their pores are more fit to receive the particles of the First Element, proceeding from some Neighbouring Body, than others. Which sometimes also happens, when the Pores of *Planets* are more adapted to admit the striate Particles, which come driving from some certain part of the *Heaven*. For these particles being entred into the Cavity of the *Planets*, do variously agitate them, directing them towards those places to which they did tend. As the *Wind* turns a *Ship* to this or that part,

part, according as it penetrates the pores of the *Sails*, or other open passages of the *Vessel*.

V.
The Fourth
Cause.

Fourthly, The same *Motion* which in the beginning of the *World* was impress'd upon the *Planets*, may be preserv'd to this instant, seeing that every *Body* continues in the same state, and is never changed but by *External Causes*. Thus a *Top* that is made to turn round by a *Boy*, hath a force to continue the same *motion* for some moments, notwithstanding the resistance it meets from the *Air* and the *Earth*. And accordingly we may believe that a *Planet* likewise hath a power to pursue the *motion* impress'd upon it at the beginning, without any considerable loss of its swiftness; because the space of 5 or 6000 years, is a less time, compared with the vast bulk of a *Planet*, than one minute, compared with the littleness of a *Top*.

VI.
The Fifth
Cause.

In the last place we may add, That the power of continuing in its *motion* is more firm and steady in the *Planet*, than in the *Heavenly matter* that surrounds it; and in a greater *Planet* more than in a less. Because the *Globuli*, which are the parts of a *Fluid Body*, cannot so well conspire in the same *motion*, as the *Particles* of the *Third Element* do, which constitute the *Compact Body* of a *Planet*. Wherefore also it must be less obnoxious to those changes that happen to the *motion* of the *Cælestial Globuli*, by how much the greater and compact it is.

VII.
The Periodical and
Daily Motion of the
Planets.

Every *Planet* hath a twofold *Motion*; the first *Periodical*, whereby every one of the *Primary Planets*, together with its *Attendants*, is carried about the *Sun*: For that they are whirl'd about in their *Orbs* by the force of the *Solar matter*, appears from hence, because the nearer they are to the *Sun*, the sooner they absolve their *Circuit*: Not to mention now the *motion* of the *Spots* in the *Sun*, which, without doubt, proceeds from the whirling about of the *Solar matter*.

The other is the *Diurnal motion*, whereby a *Planet* seems in the space of 24 hours to move about the *Earth* from *East* to *West*. But this *Motion* doth not properly belong to the *Planets*, but is common to them with the *Comets* and *Fixed Stars*, by reason of the *Diurnal motion* of the *Earth*, as will appear hereafter.

VIII.
How the
Planets are
carried about by
their Annual Motion.

A *Planet* therefore is whirl'd about its *Center*, much after the same manner, as we see that a *Trencher* swimming in a large *Vessel* full of *Water*, that is swiftly whirl'd about, doth not only follow the circular *motion* of the *water*, but besides turns about its own *Center*. The Famous *CASSINUS* observed this in 1672. in the *Body* of *Jupiter*: for he having observed a *Spot* at 7½ a clock in the evening in the midst of the *Belt*, he found at 5 a clock 26 minutes in the morning, that it was return'd precisely to the same place. And therefore from this and many other observations, he determin'd not only the *Revolution* of the *Spot*, but also of the *Body* of *Jupiter*, which he found to be performed in 9 hours 55 minutes, and 58 seconds; and the same was perceived by him not only in *Jupiter*, but also in *Mars*, *Venus* and *Mercury*.

IX.
The Cause
of these two
Motions.

This twofold *motion* of the *Planets* ariseth from hence, because the *Cælestial Globuli* that surround them, do not only carry them along their *Orbs*; but also because of the *Propension* they have, to pursue their *motion* in *Right lines*, they do more strongly exert their force upon their Ex-

ternal parts, that are more remote from the *Sun*, than upon their *Inward parts* that are nearer to it: by which force they impress that *motion* upon it, which makes it whirl about its own *Center*.

The Consequence whereof is, that the *Inferior Planets*, or those that are nearer the *Sun*, must move more swiftly than the *Higher*. Because the matter of the *First Element*, which constitutes the *Sun*, by being swiftly whirl'd about, doth with a greater force drive along with it, the nearest parts of *Heaven*, than those which are more remote.

These things presupposed, it will be an easie matter to explain the *motions* of the several *Planets*, and how it comes to pass that they seem to be carried from the *East* to the *West*. For supposing that the *Heavenly matter* that surrounds the *Sun*, is moved round it from *West* to *East*, and, without any interruption of its own *Revolution*, carries along with it the *Earth* about its *Center* in 24 hours; we shall easily conceive, that *Mercury* and *Venus* must appear to us to move from *East* to *West*, and every day to describe a *Circle Parallel* to the *Aquator*. And that they must likewise describe a *Circle* about the *Sun* from *West* to *East*, as being contained in the same matter, that carries the *Earth* round.

We shall also apprehend that these two *Planets*, as well as the *Earth*, must be found under the *Zodiack*, because it is the greatest *Circle*, which the *Cælestial matter*, by which they are carried about, describes. For as much as according to the *Law of Nature*, every *Body* that is circularly moved, endeavours to recede from the *Center* of the *Circle* it describes.

It will also appear how the *Axis* of the *Earth*, which by its *Annual motion* is carried about the *Sun*, continues always *Parallel* to it self, or which is the same, how its *Poles* always respect the same points of the *Firmament*, viz. If we observe that the *Diurnal motion* of the *Globe* of the *Earth*, *Water* and *Air* doth determinate the subtil matter, which is in continual *motion* in the *Bowels* of the *Earth*, to go forth to the *Plains parallel* to the *Aquator*; and that at the same time, a like quantity of matter, proceeding from the parts of other *Vortexes* remote from the *Poles*, must enter into it by the *Poles*. For this supposed, it will easily be believed, that after the *Earth* hath once admitted the *Subtil matter*, coming to it from one part of the *Heaven*, its pores will thereby be the more fit to receive the like matter again, than any other proceeding from other parts, as being more accommodate to it. And therefore it is no wonder, if those *Pores* which we apprehend to be *Parallel* to the *Axis* of the *Diurnal motion*, are so hollowed as to answer one another, and thereby give free admittance to the subtil matter. Which being granted, it is necessary that the *Poles* of the *Earth*, must always answer the same points in the *Firmament*, and its *Axis* observe a perpetual *Parallelism* to it self.

And the same is to be said of *Mars*, *Jupiter* and *Saturn*: For seeing that these three *Planets* do seem so to run round the *Sun*, as that the *Circles* which they describe, do include the *Circle* of the *Earth*, we must admit that they are pois'd in the *Cælestial matter* as well as the *Earth*, and are at a far greater distance from the *Sun*, than it is. In like manner we must confess that *Mars*, *Jupiter* and

the other
Planets.

Saturn must seem to run round the *Earth* from East to West in 24 hours, and to be carried away by the Heavenly matter, in the same manner as *Mercury*, *Venus* and the *Earth* are. Only with this Difference, that seeing their *Circles* are much greater than that of the *Earth*, so they employ a greater space of time in running through them. For whereas *Mercury* is whirled about the *Sun* in 3 Months, *Venus* in 8 Months, the *Earth* in a years time, *Mars* spends 2 years in his Revolution, *Jupiter* 12, and *Saturn* almost 30. For the distance between these three latter, and the *Sun* being greater, the matter which carries them, requires more time to run over those vastly greater Spaces.

XV. From these various Courses of the *Earth* and Planets in their Revolutions about the *Sun*, it comes to pass that they appear to us on the *Earth* Direct, Stationary and Retrograde. For tho' their motion be continual, without any stop or Retrogradation, yet doth the motion of the *Earth* produce these various appearances, as oft as in its Revolution it intervenes betwixt the Planets and the *Sun*. Because when the *Earth* is whirled about the same way, swifter than the Planets, we must see them answering to divers parts of the *Heaven* of fixt Stars, and to be carried opposite to that part, whither we, together with the *Earth*, are carried.

XVI. Those Planets therefore are called Direct, which pursue their Course according to the profection of the Caelestial Signs; as from γ to δ , from δ to ϵ . Planets are said to be Retrograde when they proceed contrary to the Succession of the Signs; or which having first been moved towards the East, seem now to turn back towards the West: and those are called Stationary, which keep the same place under the fixt Stars for several days together. These Stations of the Planets, are observed before and after their Retrogradations, because the Determination of the motion of the *Earth*, doth deflect a little with respect to the Determination of the motion of the Planets, by which means the swiftness wherewith we are then snatched away, doth only serve to advance us, as much as is needful, to behold that Planet which is Stationary, for several days together, under one and the same part of the Firmament.

XVII. The thing will be better apprehended by the Figure. Suppose we then the *Sun* placed in the midst of a Circle, about whom let us place the Circle $a d g k$, described by the Annual motion of the *Earth*. The other Higher Circle intersected by numeral figures, we suppose to be the Orb of some one Planet, viz. of *Mars*, *Jupiter* or *Saturn*, and the Circle NGA , to represent the Heaven of Fixt Stars. These things thus laid, let us suppose that the *Earth*, by its Annual motion is about the Point a , and that *Jupiter* is in that part of his Circle marked only by 1; then *Jupiter* will appear to those that dwell upon the *Earth*, in the part of the Heaven of fixt Stars, noted A, by the right line, $a 1 A$. Conceive we afterwards, the *Earth* to be advanced from a to b , and *Jupiter* from 1 to 2, at the same time; and *Jupiter* will appear to us to have moved on directly in the Heaven, according to the Order of the Signs from A to B; and when the *Earth* afterwards is advanced to c ; and *Jupiter* to the part of his Orb 3, *Jupiter* will be seen advanced from B to C, alway keeping a Di-

rect motion. And when afterwards the *Earth* is come to d , and *Jupiter* to 4, *Jupiter* will appear to have advanced by a direct motion from C to D. And when the *Earth* hath reached the Point e , and *Jupiter* 5, then *Jupiter* will appear to have moved from D to E, according to the order of the Signs.

But when the *Earth* begins to be more directly interposed between *Jupiter* and the *Sun*, by that time the *Earth* comes to f , and *Jupiter* to 6, then will *Jupiter* appear to have gone back from E to F; and because this interval is very small, therefore he is said to be Stationary, because he appears unmoved and standing still. The *Earth* afterwards being advanced to the point g , and *Jupiter* to 7, *Jupiter* will appear to have moved Retrograde from F to G. Again when the *Earth* is come to h , and *Jupiter* to 8, he will appear to have past Retrograde from G to H. And lastly, when the *Earth* is come to i , and *Jupiter* to 9, he will seem to have moved Retrograde from H to I, which space being very small, *Jupiter* will again appear Stationary.

Afterwards, when the *Earth* is advanced to k , and *Jupiter* to 10, he will seem to have proceeded directly, according to the Order of the Signs, from I to K. The *Earth* being come to l , and *Jupiter* to 11, he will seem to have pursued his Course directly from K to L. And lastly, when the *Earth* hath reached the Point m , and *Jupiter* 12, *Jupiter* will appear to have advanced directly from L to M.

The same may be demonstrated, not only concerning *Saturn* and *Mars*, but also concerning *Venus* and *Mercury*; which always appear Stationary, as oft as we remove from the opposite Region to the same; or from the same to the opposite Region; because the *Earth* is then so turned about, as to make them to be seen under the same fixt Stars, for some time together. These Planets appear Retrograde, when they are in opposition to the *Sun*, Direct when in Conjunction, and never so in any other places. But we are to observe, that Retrogradations are more frequently seen in *Saturn* than in *Jupiter*, and in him more frequent than in *Mars*, because of the slowness of *Saturn*'s motion, which makes that the *Earth* in a shorter time doth overtake him. But on the other hand they are more rare in *Mars*, his motion being swifter than that of *Jupiter*, and consequently must spend more time to overtake him. But these Affections are not incident to the Moon, because she, in whatsoever part of the *Earth* we are, runs about us, as about her Center, her Orb being comprehended within the Orb which the *Earth* moves in.

CHAP. XX.

Of the Motion of the Moon, and its various Appearances, or Phases.

FORasmuch as it is manifest from what hath been already said, that the Moon is not only carried about the *Sun*, but also about the *Earth*, and that there is only a small space between us and her; we may easily guess her to be contain'd in the same Vortex with the *Earth*. And consequently since the matter of this Vortex, doth whirl the *Earth* about its Center from West to East, we may

may conclude that it also carries the *Moon* along with it. But since the *Circle* which the *Moon* runs through, is almost 60 times bigger than the *Compass* of the *Earth*, we may gather, that if the *Earth*, by its diurnal motion is whirled about its *Center* in the space of 24 *Hours*, the *Moon* will not be able to finish her *Revolution* in less than about a *Months* space.

II. The *Moon* may appear to move from West to East, or contrarily, within the space of one Month.

III. What the *Perigæum* and *Apo-gæum* of the *Moon* is.

Figure 29.

IV. The *Moon* seems to move swifter when *New* and *Full*, than at the *Quarters*. The Reason whereof is, for that her *Vortex* A B C D, by being press'd upon by the *Orbs* of *Venus* and *Mars*, between which it is placed, is thereby reduc'd to an *Elliptical* or *Oval* *Figure*. Hence it is that the *Cælestial* *Matter* moves more swiftly in the narrow Parts B and D, of this *Elliptical* *Heaven*, and more slowly in the broader Spaces A and C; and therefore the *Moon*, in her *Conjunction* and *Opposition*, or at the *New* and *Full*, must be more swiftly carried about the *Earth* towards the *East*; because the Spaces it then runs through are more narrow, and do not suffer it to wander.

V. Why the *Moon* is not exactly moved under the *Equator*.

VI. Above one half of the *Moon* is always illustrated by the *Sun*.

This long time the *Moon* spends in her *Revolution*, is the Cause that she seems to run round the *Earth* every Day from *East* to *West*, whilst in the mean time the *Earth* turns round from *West* to *East*. Tho' this doth not hinder the *Moon* from appearing to run through all the *Signs* of our *Zodiack* from *West* to *East*.

The *Moon* is sometimes nearer to the *Earth*, and that is her *Perigæum*; and at other times further from it, which is her *Apo-gæum*. This comes to pass, either because the *Peculiar Vortex* of the *Earth* A B C D, is sometimes bigger, by reason of the *Matter* of the *First Heaven* more abundantly crowding into it; and at other times becomes less, because of the *Expulsion* of it again. Or else, because the *Moon* is more or less push'd on towards the *Earth*, by the various agitation of the *First Heaven*.

The *Moon* seems to move swifter when *New* and *Full*, than at the *Quarters*. The Reason whereof is, for that her *Vortex* A B C D, by being press'd upon by the *Orbs* of *Venus* and *Mars*, between which it is placed, is thereby reduc'd to an *Elliptical* or *Oval* *Figure*. Hence it is that the *Cælestial* *Matter* moves more swiftly in the narrow Parts B and D, of this *Elliptical* *Heaven*, and more slowly in the broader Spaces A and C; and therefore the *Moon*, in her *Conjunction* and *Opposition*, or at the *New* and *Full*, must be more swiftly carried about the *Earth* towards the *East*; because the Spaces it then runs through are more narrow, and do not suffer it to wander.

If the whirling about of the small *Vortex* A B C D, which carries the *Moon* along with it, did only accord with the *Motion* of the *Earth*, then the *Moon* would appear to move under the *Equator* from *West* to *East*; and on the contrary, if the *motion* of the said *Matter* should only agree with the *motion* of that great *Vortex*, which has the *Sun* for its *Center*, then it would only be seen under the *Ecliptick*. But seeing it is to agree with the *motion* of them both, it follows, that its *motion* must neither be under the *Equator*, nor under the *Ecliptick*, but under another *Third Circle*, which comes nearer to the *Equator*, than the *Ecliptick*; because the *Moon* is nearer to the *Matter* of the *Sun's Vortex*, than to that of the *Earth*.

The *Moon* being a *Round Body*, and receiving its *Light* from the *Sun*, it follows, that always one half of it, yea, somewhat more, must be enlightened by him. For seeing that the *Sun* exceeds the *Moon* in *Bigness*, and that the bigger *Sphere* always enlightens above half of a less, it does follow, that above one half of the *Body* of the *Moon* must always be illuminated. But seeing that the *Moon* alters her *Position*, and in running about the *Earth* doth variously face the *Sun*; it must needs be, that according to its various Access to, or Recess of the *Sun*, less or more of the illuminated Half will appear to us; which Variations of

her *Appearance*, are commonly called her *Phases*.

The *Philosophers* commonly reckon up four *Phases* of the *Moon*, according to the *Fourfold* respect which the *Moon* hath to the *Sun*, in different parts of the *Zodiack*. Whence it receives different Names; for the *Moon's* meeting with the *Sun* in the same Degree of the *Zodiack*, is called the *Conjunction* or *New Moon*. Tho' it seems that the *Moons Conjunction* with the *Sun*, ought not to be accounted amongst her *Phases*; because the *Moon* at that time doth not appear to us at all, its enlightened part being wholly turn'd away from us, and its dark part turn'd towards us.

The first *Phase* therefore of the *Moon* is, when she being newly come from her *Conjunction* with the *Sun*, by moving in her *Orb* A B C D E F G H, reacheth B, whence she appears to us on the *Earth* I, *Horned* (or *Crescent-wise*) because of the *Hollowness* which is seen in her *Illuminated* part.

The second *Phase* is, when the *Moon* about the *Seventh* or *Eighth* day, being 90 Degrees distant from the *Sun*, doth represent the full Half of her *Enlightened* part C, whose *Horns* or *Points* are directed to that part of *Heaven* which is opposite to the *Sun*, as from whence it receives its *Light*. and here she appears *Bisected*, or divided into two *Halves*.

The third *Phase* is, when the *Moon* D, advancing towards an *Opposition* with the *Sun*, exhibits to us more than one half of her *Illuminated* part, and therefore appears *Gibbous* or *Bunching out* on both sides.

The fourth *Phase* happens, when the *Moon* E being 180 Degrees distant from the *Sun*, and in *Opposition* to him, turns her whole *Enlightened* side towards us, who are placed betwixt the *Sun* and her.

The same *Phase* also belong to the *Moon* in *Decrease*, according to her various Aspects to the *Sun*. For when by going back she hath reach'd F, she appears *Gibbous*; when to G, *Half*; and at H, *Crescent-wise* again; till returning to A, her *Enlightened* part be wholly turn'd away from us towards the *Sun*.

The *Moon* is never less *Enlightened* than when she is at the *Full*, or in *Opposition* with the *Sun*; and never more than at the *New*, or when she is in *Conjunction* with the *Sun*; because when she is *Full*, only that part towards us is *Enlightened*: Whereas when *New*, she is wholly *illuminated*, that part which is then towards us being *Enlightened* by the *Earth*, and the other part that is turn'd from us, by the *Sun*. For the *Moon* doth not only borrow her *Light* from the *Sun*, but receives also some weak *illustration* from the *Earth*: Because the *Earth* being an *Opake Body*, must of necessity reflect part of her received *Light*; and forasmuch as the *Earth* is bigger than the *Moon*, consequently more *Light* must be deriv'd from the *Earth* to the *Moon*, than from the *Moon* to the *Earth*. This is confirm'd by Experience, because this *Secondary Light*, as *GALILÆUS* calls it, after the first *Quarter* quite vanisheth, by reason of the *Moon* being too far distant, and without those Bounds to which the reflected *Beams* from the *Earth* reach.

VII. The *Conjunction* of the *Moon* with the *Sun*, is not to be accounted amongst her *Phases*.

VIII. The first *Phase* of the *Moon*. Figure 30.

IX. The second *Phase* of the *Moon*.

X. The third *Phase* of the *Moon*.

XI. The fourth *Phase*.

XII. The same *Phase* happen to the *Moon*, when she is in the *Wane*.

XIII. The *Moon* is more illuminated at the *New*, than at the *Full* *Moon*.

XIV. We know likewise by Experience, that this *Light* is more perceptible when the *Moon* is *Eastward* from us, than when she is *West*. The Reason whereof is, because in the former situation, the *Light* is reflected to her from all the *Continent* of *Asia*, and part of *Africa*, which are more proper to reflect the *Sun-beams*, than those *Seas* which are towards the *West*. So that as the *Moon* doth at some times Enlighten the *Earth*; so at other times again, the *Earth* Enlightens the *Moon*.

XV. The *Moon* performs her *Revolution* in 27 Days and about 8 Hours; and this time is called the *Periodical Lunar Month*: And the time that intervenes betwixt the *Conjunction* of this *Planet* with the *Sun*, till the next *Conjunction*, is called the *Synodical Month*; which consists of 29 Days, and about 12 Hours. Wherefore, when on a certain Day there is a *Conjunction* between the *Moon* and the *Sun*, the *Moon* indeed will return to the same Degree of the *Zodiack*, at the end of 27 Days and near 8 Hours; but she will not meet with the *Sun* there, who by this time will be advanced 27 Degrees further to the *East*; so that the *Moon* will be fain to proceed two Days longer before she can overtake him.

CHAP. XXI.

Of the Eclipses of the Sun and Moon.

I. Forasmuch as the *Earth* by its *Annual Motion*, turns round about the *Sun*; and the *Moon* by her *Monthly Revolution*, is whirled about the *Earth*, it cannot be but that the *Earth*, *Sun* and *Moon* must sometimes meet, and be oppos'd to one another. Whence, if it so happens, that by the *Moons* intervening betwixt the *Sun* and the *Earth*, the *Sun* becomes obscured by her shadow, this we call an *Eclipse* of the *Sun*, because its *Light* is hindered from being diffused on the *Earth*. So that the *Eclipse* of the *Sun*, is nothing else, but a *Failing of Light* in some Region of the *World*, caused by the *Diametrical Interposition* of the *Moon* betwixt the *Sun* and that *Country*. Wherefore this *Eclipse* always happens at the Time of the *Moons Conjunction* with the *Sun*.

II. But if the *Moon* come within the verge of the *Earth's shadow*, and by this means be deprived of the *Light* it borrows of the *Sun*, this we call an *Eclipse* of the *Moon*. And accordingly, an *Eclipse* of the *Moon* is a *Failure of Light* in the *Moon*, because of the *Diametrical Interposition* of the *Earth* between the *Sun* and the *Moon*. For then is the *Moon* obscured by the shadow of the *Earth*, and it happens always at the *Full Moon*, or *Opposition*: Tho' this Observation be not perceiv'd by all the *Inhabitants* of the *Earth*; but by those only that are in that part of the *Earth*, which is *Diametrically interpos'd* between the *Sun* and *Moon*.

III. An *Eclipse* of the *Moon* is either *Total*, or *Partial*. A *Total Eclipse* is, when the whole Round of the *Moon* is cover'd with the *Shadow* of the *Earth*: Whereas in a *Partial*, a part of it only is obscured.

IV. Betwixt these two *Eclipses* we are to observe this considerable difference, that the *Failure of Light*

in the *Moon*, is caused by the *Interposition* of the *Earth*, which really keeps off the *Sun's Rays* from it, hindring it from receiving its wonted splendour. But no such *Defect of Light* ever happens to the *Body* of the *Sun*, whose *Light* cannot be the least impair'd, because of the *Moons* *Interposition* between him and the *Earth*. And therefore an *Eclipse* of the *Sun*, may with more propriety of Speech be called an *Eclipse* of the *Earth*, the *Defect of Light* being only in *Appearance* in the *Sun*, but really and indeed in the *Earth*, which is then deprived in a greater or less degree of his *Light*.

We are to observe that, as the way of the *Sun*, or the *Ecliptick*, doth obliquely intersect the *Equator* in the two opposite *Aequinoctial Points*; so likewise the *Orb* of the *Moon* is not directly under the *Ecliptick*, but cuts the same in two opposite Points at *Oblique Angles*; and these Points are called the *Nodes*, or the *Dragons Head* and *Tail*. For the clearer conceiving whereof we are to note, that the *Ecliptick* divides the *World* into two Parts, whereof that which contains the *Northern Pole*, is called the *Northern part*; as that which contains the opposite *Pole*, the *South part*. This suppos'd, we say that the *Dragons Head* is one of the *Common Sections* of the *Ecliptick*, as well as of the *Circle* which the *Moon* describes, when she passeth from the *South part* of the *World* to the *North*; and the other Section, by which the *Moon* passeth from the *North* to the *South part* of the *World*, is the *Tail* of the *Dragon*. The *Orb* of the *Moon* therefore, A B C D, doth not concur with the *Sun's Ecliptick* A E C F, but intersects the same in two places, at A and C. In 31. or very near which Intersections the *Sun* and *Moon* must be, or else no *Eclipse* can happen. For beyond the *Ecliptical Terms* G H I K, there are no *Eclipses*; because every where else the *Moon* is either too high towards the *North* B, or too much depress'd towards the *South* D; so that where there is not a *Conjunction*, or an *Opposition* of these three Bodies, the *Sun*, *Moon*, and the *Earth*, at the *New* or *Full* of the *Moon*, neither *Solar* nor *Lunar Eclipse* can ever happen.

Wherefore we see, that the *Eclipse* of the *Sun* can only happen at the *New Moon*, when the *Sun* and *Moon* are in *Conjunction*. For since the *Orb* of the *Moon* only intersects the *Ecliptick* at two Points or *Nodes*, she must of necessity be found in one of these before she can cause an *Eclipse*. And forasmuch as the *Sun* meets twice only in a Year with the *Moon*, in or at those *Nodes*, the *Sun* cannot suffer an *Eclipse* more frequently, than about every sixth Month. The *Moons motion* also from *West* to *East*, being not always exactly under the *Ecliptick*, but deviating something from it towards the *North* or *South*, and consequently not moving directly between the *Sun* and us, it is apparent that no *Eclipse* can be, but when the *Sun* and *Moon* are together in the *Dragons Head* or *Tail*, which, as I said, happens but every sixth Month.

Accordingly the *Eclipse* of the *Moon* happens, when the *Earth* a, being directly interpos'd between the *Moon* b or d, and the *Sun* c, doth by its *Conical shadow* l b i, hinder the direct *Rays* of the *Sun* from reaching any part of the *Body* of the *Moon*, as in b and d, or only from illuminating some part

more properly be called an Eclipse of the Earth.

V. What the Head and Tail of the Dragon is.

Figure 31.

VI. The Eclipse of the Sun ever happens at the New of the Moon.

VII. The Eclipse of the Moon happens only at the Full, tho' not at every Full Moon.

Figure 32. part of it, as in *e* and *f*. The *Eclipses* of the *Moon* are only at the *Full Moon*, that is, whilst the *Sun* and the *Moon* are diametrically oppos'd in the *Dragons Head and Tail*; because then the *Earth* comes between them, and by its *Shadow* does obscure the *Moon*. Yet it doth not follow from hence, that there must be *Lunar Eclipses* every *Full Moon*; because the *Moon* having some *Latitude*, she is often at the time of her *Opposition* to the *Sun*, at a considerable distance from the *Nodes*, whence it happens that the *Shadow* of the *Earth* does not touch her; there being no possibility of an *Eclipse*, except the *Sun* and *Moon* be in the *Head and Tail* of the *Dragon*. And forasmuch as the *Sun* cannot be there above twice in a Year, it is evident, that we cannot have a *Lunar Eclipse* every *Full Moon*.

VIII. A *Total*, or *Partial Eclipse* is caused, when the *Luminaries* are in *Opposition*, as in the *Lunar*; or in *Conjunction*, as in the *Solar Eclipse*, in or near the *Nodes*, or else at a little distance from them: For seeing that the *Axis* of the *Earth's Shadow* is always in the *Plain* of the *Ecliptick*, it cannot be otherwise, but that when this *Axis* coincides with the *Nodes*, the *Moon* passing that way, or near to it, must be wholly dipp'd in the *Shadow* of the *Earth*; but when more remote, then the *Moon* must be only in part obscured, as entering only into the verge or brim of the *Shadow*. And so likewise in the same manner, because the *Axis* of the *Lunar Shadow*, the *Sun* being behind it, doth then appear, when the *Moon* is in the *Ecliptick* or *Node*: Therefore it is necessary, that at that time when it doth not appear less than the *Sun*, it must cover the whole *Sun*, which otherwise covers only some part of it; viz. when the *Axis* of that *Shadow* being somewhat turn'd aside from our *Sight*, a part of the *Moon* only comes between us and the *Sun*.

IX. A *Total Eclipse* of the *Sun* is a thing seldom seen; for the *Moon* being much less than the *Earth*, cannot but rarely be so conjoyn'd with the *Sun*, as to cover its whole *Round*, and hinder the *Light* proceeding from it to reach the *Earth*; but only so, as to cover some part of it with its *Shadow*. Besides, forasmuch as the *motion* of the *Sun* from *West* to *East* is very swift, she makes haste away from under the *Sun*, and therefore can only obscure it for a very short time. So that tho' we should suppose the *Moon* to be so conjoyn'd with the *Sun*, that his *Light* might appear to be totally intercepted; yet could not the *Failure of Light* last above a *Moment*, seeing that in the next following *Moment*, some of its *Light* would be diffused from that part of the *Sun's Body*, which by that time would be got out of the *Shadow*.

X. Thus it often happens, that tho' a *Total Eclipse* be perceived in some part of the *Earth*, yet in other parts the same is only *Partial*, and in other again *none at all*. This will clearly appear in the *Scheme* or *Figure*, where the *Moon a*, being interpos'd between the *Sun b*, and the *Earth c*; it is manifest that the *Inhabitants* at the *Point d* will be deprived of the whole aspect of the *Sun*, because of the interposition of the *Moon*; they who dwell at the *Point e*, will be depriv'd of the one half of it; whereas no part of the *Sun* will be obscur'd to them who live at *f*; and the same is to be understood of all other the *Inhabitants* of the *Earth*,

from whom the *Moon* turns away the *Sun-beams* more or less, according to their several situations.

This acquaints us with the Reason, why a *Lunar Eclipse* is perceiv'd in one and the same manner, by all those that are in the same *Hemisphere*, and have the *Moon* above their *Horizon*; but not the *Eclipse* of the *Sun*, which appears to some *Total*, to others *Partial*, and to others again *None at all*.

For the *Moon* being destitute of all *Light* of her own, must needs be perceiv'd alike obscur'd by all: Whereas the *Sun*, being *Lucid* of it self, cannot appear destitute of all *Light*, but only so far as it is cover'd by the *Globe* of the *Moon*, which intervenes between the *Sun* and the *Earth*; and forasmuch as the *Lunar Globe* is less than the *Sun*, or the *Earth*, it can no otherwise happen, but that some part of the *Earth*, to which the *Moon* appears equal to the *Sun*, or greater, must be depriv'd of the whole *Light* of it; whereas others, to whom it appears otherwise, are but deprived of the *Half*, or of more or less of its *Light*, and others again enjoy the whole *Light* of it.

The *Solar Eclipses* are not so frequent as the *Lunar*; for the *Body* of the *Moon*, which deprives us of the *Sun-beams*, being much less than the *Earth*, which deprives the *Moon* of *Light*, it cannot be otherwise, but that the *Moon* must more frequently meet with the *shadow* of the *Earth*, than our *Sight* meets with the *shadow* of the *Moon*. But this is not to be understood of the whole *Round* of the *Earth*, but only with respect to some determinate *Part* of it, as by *Example*, that place where we live: For otherwise there is no question, that every six Months *Solar Eclipses* happen in this or the other part of the *Earth*, and no less frequent than the *Lunar Eclipses*.

The *Duration* of *Eclipses* is not always the same. If it be enquir'd, what the greatest *Duration* of a *Solar Eclipse* is; GASENDUS in his *Astronomical Institution*, determines it to be the *Space* of about 2 *Hours*. For seeing that the *Moon* spends a whole *Hour* from the time that she hath made a beginning of the *Eclipse*, by touching the *Western* brim of the *Sun*, with her *Eastern*, until the time that the same brim come to the *Eastern* part of the *Sun*, and thereby make the midst of the *Eclipse*; and because then only the *Western* brim of the *Moon*, is advanced to the *Western* brim of the *Sun*, which soon after it quits wholly: So that as soon as the *Incidence* ceaseth, the *Emersion* begins; it necessarily follows, that she must spend another *Hour*, before the same brim can reach the *Oriental* part of the *Sun* again, and wholly quitting it, put an end to the *Eclipse*.

The *Superiour Planets* suffer no *Eclipses*, when the *Earth* comes between them and the *Sun*; because the *Conical shadow* of the *Earth* cannot reach them. Yet those *Planets* that have any *Assistent Stars*, are subject to *Eclipses* by their *Interposition*, as is evident from *Observations* about *Jupiter* and *Saturn*.

XI. Why the Eclipse of the Sun never appears Total to all the Inhabitants of the Earth.

XII. Eclipses of the Sun are less frequent, than those of the Moon.

XIII. How long the greatest Eclipse of the Sun lasteth.

XIV. Why the Superiour Planets are not subject to be Eclipsed.

C H A P. XXII.

Of the Fixed Stars.

I. **THE** Fixed Stars are so called, not because they rest without any motion at all, or because they are fastned to the Heaven, as so many Nails, but because, being seated in the Center of their several Vortexes, they always keep the same situation and distance from one another. So that the Fixed Stars are Lucid Bodies, consisting of the matter of the First Element flowing to the Center of the Vortex, and succeeding in the room of the Globuli that recede from thence, giving forth light from themselves, and much differing in Magnitude from each other.

II. Tho' there seem to be an immense distance between us and the Planets, yet is the space that reacheth from the Earth to the Fixed Stars, much greater, because the Planets do sometimes hide the Fixed Stars, which they could not do, if they were not interpos'd between us and them, and consequently lower than the Fixed Stars. Moreover, forasmuch as the Astronomers have not as yet found out any thing, whereby to measure this vast distance, we may suppose it to be as great as we please.

III. That the Fixed Stars are higher than the Planets, the Astronomers prove from the Parallax or Commutation of our Sight. They conceive two lines, the one drawn from the Center of the Earth, the other from its Surface, or from the Eye of the Spectator, through the Center of a Planet, and reaching to the Firmament beyond it. That which is drawn from the Center of the Earth, will be highest; whereas that which is drawn from the Eye of the Beholder is lower and more depressed, unless when they both end in the same Vertical Point. And forasmuch as the Point, in which the First Line is terminated, is accounted to be the true place of the Planet, and the Point in which the other line ends, the Apparent or seen place of the Planet, it is easily apprehended, what the Parallax is, viz. the difference or distance that is found betwixt both these places. Forasmuch therefore as there is no Planet that hath not some Parallax, the Astronomers infer, that the Region of the Fixed Stars is at a greater distance from the Earth than any of the Planets. For there would be no Parallax or change of the Sight, in case any Planet were as far from the Earth, as the Fixed Stars.

IV. The Sun is the greatest of all the Fixed Stars as to us, for that by reason of his nearness to us, he doth more strongly move the Luminous matter; for there is no question, but that if the Sun were beheld from the Fixed Stars, it would not appear any greater than they do. Yea, GALILEUS gathers that the Fixed Stars themselves, have greater appearing Diameters, their immense distance considered, than agrees with the common Astronomical Calculations, because if we take away their Beams, the Diameters of the Fixed Stars by this means become much less.

V. All the Fixed Stars are not placed in the Circumference of one Sphere, as some have imagined, by giving too much credit to their Senses; but as the Sun hath a space about it, in which no Fixed Star is contained; so likewise every Fixed Star must be supposed to be at a vast distance from any other,

and some of them at far greater distance from us and the Sun, than others of them. So that the inequality which is discerned to be betwixt the Fixed Stars, will be as much from their greater or less distance, as from the greater or less Bulk of their Bodies. And tho' the Region wherein the Fixed Stars are, appear Spherical to our Eye, yet would it be irrational to undertake to determine any thing concerning the figure of any Body, whose outward and inward Surface cannot be discovered by us.

VI. For it is notorious, that Bodies of equal bigness, by reason of their unequal distances, appear to be unequal. Now to suppose all the Fixed Stars to be in one Plane, is not so much as probable, neither is there any reason to prove it: for tho' they be at vast distances from one another (which we boldly do assert) yet will they seem to be in one and the same Plain, after the same manner as Planets, Fixed Stars and Clouds seem to be in the same Plain, yea, and to touch the very Horizon, because there is nothing interposed between them, and our sight, whereby we may judge of their distance: And I durst lay it down for a general Rule, that all distance vanisheeth, where we have no Sense nor Judgment of the intervening Bodies.

VII. The Fixed Stars have a light of their own, as we have shewed in the foregoing part of this Discourse, that the Sun hath, whom we take to be one of the Fixed Stars; there being no other Lucid Body whence he might borrow his Light, in case he had it not in himself. And the same is evident also concerning the rest of the Fixed Stars, from the briskness of their Beams, and their vast distance both from us, and from the Body of the Sun, so that they cannot borrow any part of his Light. For we frequently perceive the Body of the Sun, covered with Spots, which like so many Clouds cover his Face, and by resting the Pressure of the Light, suffer only some languid Beams to proceed from him to us; and this, as Historians tell us, hath sometimes continued for a whole year together, and hath made the Sun all that while to appear with a pale whitish Light, like that of the Moon: And yet the Fixed Stars, during this time, were never found to have lost any thing of their Light; which must have followed in case they had received their Light from the Sun.

VIII. Again, that the Fixed Stars are of a fiery Nature, and like the Sun, shine with their own Light, may be thus proved; because if the Sun should be viewed from the Fixed Stars, it would appear no greater than one of the least of them; and therefore if the Sun were removed from us, as far as they are, its bulk would appear so much lessened, as scarcely to be conspicuous. And again, if we should suppose the Dog-Star, to be placed where the Sun now is, it would appear as great and glorious as the Sun now appears to us. Now this vast distance of the Sun from the Fixed Stars, sufficiently proves that it is impossible they should borrow their Light from him. Wherefore we must conclude, that the Light of the Fixed Stars, doth not at all differ in nature from that of the Sun, as consisting only, on their part, in the swift agitation of the matter of the First Element; and with respect to the Medium, in the motion they communicate to the Globuli of the Second Element, intervening between those Stars and us.

All

IX.
Why the
Fixt Stars
twinkle.

All the *Fixt Stars* do seem to *Twinkle*, the reason whereof is the strength and briskness of their *Rays*, whereby they strike upon our *Eyes*. Which appears from hence, that when we look upon them through a *Telescope*, their *Twinkling* is much diminished, the strength of their *Rays* being much weakned, by passing through the small holes thereof. Another cause of their *Twinkling* is, because their *Vortexes*, which on every side encompass our *Heaven*, are not perfectly round, but have irregular *Surfaces*, as may be seen in *Figure 20*: whereby it happens, that whirling about their *Centers*, and acting upon our *Heaven*, the *Rays* of the *Stars* come to fall obliquely upon it, and by that means are refracted; from which *Refraction* their *Scintillation* or *Twinkling* follows. The said *Scintillation* may also be caused by the agitation of *Vapours* and *Exhalations* in the *Air*; as we see little *Pebbles* that lie without any motion at the bottom of a *River*, do seem to shake, by reason of the continual flowing of the *Water*.

X.
How it
comes to
pass that
the Stars
do not ap-
pear in
their own
places.

For the same reason also it is that the *Fixt Stars*, are not seen by us in the same places, wherein they are indeed, but as if they were placed in the surface of our *Great Vortex*, which hath the *Sun* for its *Center*. And here they cannot appear in their own places, because the *Surfaces* are in a manner, never so disposed, that the *Rays* which pass through them, from these *Stars* to the *Earth*, do meet with them at *Right Angles*; for when they meet with them obliquely, it is necessary, according to the *Rules of Refraction*, that they must bend a little, because they pass more easily, by one of the sides of these *surfaces*, than by the other.

XI.
The Fixt
Stars seem
to move.

Tho' the *fixt Stars* are contained in their *Vortexes*, and always keep the same distance from one another, yet they seem to move, not only by a *Diurnal motion*, by reason of the *Earth's Revolution* about its own *Center*; but also by another motion, according to which every *Star* seems to encrease its *Longitude*; ever since that time, when *HIPPARCHUS* 130 years before *Christ*, observed that the *Fixt Stars* had a motion like the *Planets*, from *West* to *East*; having taken occasion for making this Discovery from some observation of *TIMOCHARIS* and *ARISTILLUS*. For when *TIMOCHARIS*, amongst other *Stars*, had observed, that the *Spica Virginis*, was almost 8 degrees antecedently distant from the point of the *Autumnal Equinox*, He found the same *Star* to be only removed six degrees from the said point. From which observation he concluded, that they move by this motion about one degree, in the time of 100 years; and consequently that the *Fixt Stars* also had a motion of their own.

XII.
What the
cause is of
this ap-
pearing
motion.

In order to the Explication of this appearing motion of the *Fixt Stars*, we are to suppose, that the *Axis* of the *Diurnal motion* of the *Earth*, doth not accurately keep the same *Parallelism* in its *Annual Revolution* which it had before, but somewhat turns aside from the same, after the running out of a great many years; and tho' this *Deflexion* from the *Axis* of the *Ecliptick* be insensible; yet the *Earth*, by this *Reeling motion*, in the space of many thousand years, is the cause that its *Poles* describe a small *Circle* from the *East* to the *West*. And since that according to this

Hypothesis we conceive the *Aequator of the Earth* to answer to different parts of the *Heaven*, it follows that the *Celestial Aequator* must also change its place, and cut the *Ecliptick* at divers *Points*, from *East* to *West*. And because the *Longitude* of the *Fixt Stars* is computed from that time, in which these two *Circles* are intersected, it cannot be, but that the said *Longitude* must seem to be encreased every hundred years.

This will appear more manifestly, if we suppose that the *Declination* of the *Axis of the Earth* from the *Perpendicular* to the *Plane* of the *Ecliptick*, proceeds from the *Striate Matter* of the *First Element* (as shall be explained more at large in the sixth Part) which coming from that part of the *Second Heaven*, which is 23 degrees distant from the *Poles* of the *First Heaven*, and passing through its *Poles*, doth incline it to so many degrees. But because that part of the *Second Heaven*, which is fit and dispos'd, to drive the *Striate Matter* into the *Poles* of the *Earth*, and by this means to sway them obliquely, is insensibly turned round from 1 to 2, and from 5 to 6, and so on, according to the trace of the *Polar Circles* 1, 2, 3, 4, and 5, 6, 7, 8, which in this our age, are 23 degrees distant from the *Poles* of our *First Heaven A C*; Figure 34- whilst, in the mean time, the *Earth*, together with the rest of the *Planets* is moved in its *Annual motion*, according to the Succession of the *Signs* of the *Zodiack* from *Aries V* to *Taurus 6*, and from *Taurus* to *Gemini II*, and so on, by a contrary Motion to that of the *Second Heaven*, that communicates the *Striate Matter* to the *Earth*; by this means it comes to pass that the *Poles* of the *Earth* are by little and little turn'd about, respecting those *Polar Circles* at this time, with an inclination of 23 degrees, contrary to the course of their *Annual Motion*: So that the *Poles* of the *Earth*, which were directed to the parts of the *Polar Circles* marked *N O*, are now directed, to those parts of them that are marked *L M*.

Neither only is that part of the *Second Heaven*, which sends the *Striate Matter* to the *Poles* of the *Earth*, and directs or inclines them according to the trace of the *Polar Circles* 1, 2, 3, 4, and 5, 6, 7, 8, swayed about, but it is also lifted up to the *Poles A C*, of our *Heaven*, and is again by them, in that wrestling about, softly depressed. And this is the Cause, why the *Axis* of the *Poles* of the *Earth* I, doth now decline 23 degrees and 30 minutes, according to the magnitude, for Example, of the *Line L M*, or *N O*, from the *Poles A C*, of our *Heaven*, whereas formerly this *Declination* was of whole 24 degrees.

Wherefore altho' the change which happens to the *Longitude* of one *Star*, cannot but be like to that which happens to another; yet it is not necessary, that all the *Fixt Stars* together, should throughout all *Ages* obtain the same *Longitude*, since it is possible that this *Reeling* of the *Earth*, may be more sensible in this Age than in another. And therefore the Irregularity of the Apparent motion of the *Fixt Stars*, may be easily explained, by supposing, that the *Reeling* or *Titubation* of the *Earth* is not *Regular*; and that in some *Ages* it deflects somewhat more, and in others less.

We may likewise easily comprehend, that the apparent *Ecliptick*, must somewhat alter its *declination*, provided we conceive, that during this *Titubation*

XIII.
Why the
Poles of the
Earth are
by little
and little
obliquely
turned the
contrary
way to its
Annual
motion.

XIV.
The Longi-
tude of the
Fixt Stars
may be un-
equal.

XV.
How the
Change of
the Declina-
tion of
the Eclip-
tick is
made.

tubation of the Earth, its *Axis* inclines towards the plain of the *Ecliptick*, somewhat more at one time than another; for thus the *Aequator* of the Earth, determines that of the *Heaven*, in parts that are at such different Distances from the *Ecliptick*. Now this *Reeling motion* of the Earth, follows necessarily from its being placed in the *Vortex* of the *Sun*: For it would be a great wonder, if being plac'd in the midst of a *Liquid matter*, as it is, it should continue there many Ages, without admitting any change in its situation.

XVI. The *Fix'd Stars* are not seen by us in the day time, because the impression of the *Sun's Brightness* is so strong on our *Eyes*, that the *Light* of the *fix'd Stars* cannot make it self perceptible. The case is the same, as when our *Ear* being flun'd with some great *Noise*, cannot perceive any low or weak sound: Or, as a *hot Hand* cannot distinguish the less sensible warmth that is in another *Subject*. Yet doth not this hinder, but that a *Man* plac'd at the bottom of a *Well*, may perceive the *Light* of the *fix'd Stars*; because there his *Eye* is not so strongly affected by the splendour of the *Sun*; neither doth any thing hinder a *Star* that is above the *Horizon*, from freely transmitting his *Rays*.

CHAP. XXIII

Of the Asterisms and Constellations.

I. **T**HO' the *Fix'd Stars* be dispers'd throughout the immense Space of *Heaven*, and can no more be numbred than the *Sand* on the *Sea-shoar*; yet the *Astronomers* have been pleased to determine a certain Number of them, which they have discover'd by the help of their *Telescopes*, as being nearer to us, and more in view. Of these they count 1022; which they have divided into 6 *Classes* or *Ranks*.

II. The greatest *Stars* of all are called, *Stars of the First Magnitude*; and of these there are 15.

The next to these are called, *Stars of the Second Magnitude*, of which there are 45.

After these follow those that are of the *Third Magnitude*, being 208 in number.

Of the *Fourth Magnitude*, there are 474.

The fifth *Classis* of *Stars*, are those of the *Fifth Magnitude*; and of these there are 217.

The sixth *Rank* or *Order* of *Stars* contains 49, and are the least of all. To which, for the making up of the Number, 9 *Stars* called *Obscure*, are added, and 5 called *Misty* or *Cloudy*, because they can hardly be perceived.

III. It is to be observ'd, that all the *Stars* that are of one *Classis*, do not appear to us of the same *Bigness* and *Brightness*; but in every one of these *Divisions*, there are some that are Greater, some Less, and some of a *Midling-size*, between both. For the *Dog-Star* is the biggest of them all; and tho' the *Lyre* or *Harp* be of a very conspicuous *Magnitude*, yet can it not be compared with it; and the same may be said of the other *Orders* or *Divisions*. For the *Eye* of the *Bull* doth far exceed the *Lions-Heart*, and the *Virgins Ear* of *Corn*.

IV. To the end these *Stars* might be the better distinguish'd and remembred, the *Astronomers* have reduc'd them to certain *Constellations*, and affixed some *Signs* or *Figures* to them, according as they imagin'd them to have some resemblance or

agreement with such and such *Animals* or *things*.

The *Astronomers* reckon up 48 of these *Figures* or *Constellations*, whereof some are in the *Zodiack*, others without it in the Northern and Southern Hemisphere.

In the *Zodiack* are 12 *Constellations*: *Aries*, or the *Ram*, express'd by this Character γ , as representing the *Head* and *Horns* of a *Ram*: *Taurus*, or the *Bull*, the *Head* and *Horns* of an *Ox*: *Gemini*, or *Twins*, II , two *Bodies*, with their *Arms* and *Legs* twisted together: *Cancer*, the *Crab*, C , the *Claws* of a *Crab*, with their *Retrograde* going: *Leo*, the *Lion*, L , representing a *Lion's Tail*: *Virgo*, the *Virgin*, V , resembling a *Wing*, or the folded *Gown* of a *Damsel*: *Libra*, the *Balance*, B , the *Beam* of a pair of *Scales*: *Scorpius*, the *Scorpion*, S , the *Body* and *Tail* of a *Scorpion*: *Sagittarius*, the *Archer*, A , an *Arrow*, apply'd to a *Bow*: *Capricornus*, W , the *Head* and *Horns* of a *Goat*, with the *Tail* of a *Fish*: *Aquarius*, the *Waterman*, W , the pouring of *Water* out of a *Pitcher*: *Pisces*, the *Fishes*, F , two *Fishes* tied together with a *String*.

The *Astronomers* attribute to each *Sign* of the *Zodiack* 30 *Degrees*, tho' the *Asterisms* themselves be unequal, some of them being shorter, and others longer: For if 360 be divided by 12, the result will be 30.

In *ARIES* 3 *Stars* are most conspicuous, 2 in the left *Horn* of the fourth *Magnitude*, and 1 of the third, between the *Horns*; which *Tycho* calls the *Bright Star* in the top of the *Rams Head*.

The most considerable *Star* in the *Sign* *TAURUS* is placed in his left *Eye*, being a *Star* of the first *Magnitude*, and is therefore called the *Bulls Eye*. Near to it are other 5 *Stars*, which are called *Hyades*: And those 6, formerly 7 *Stars*, that appear on the *Back* of the *Bull*, are called *Pleiades* and *Vergiliae*, in the midst of which is a *Star* of the third *Magnitude*, commonly called the *Bright Star* of the *Pleiades*.

There are 2 *Principal Stars* in *GEMINI* of the second *Magnitude*, whereof that in the North *Head* of the *Twins*, is called *Castor*; as that in the South, *Pollux*. There is also another *Star* of the same *Magnitude* in the right *Foot* of *Pollux*, towards *Orion*. There is also one of the fourth *Magnitude*, called *Propus*, because it is placed near the left *Foot* of *Castor*.

In *CANCER*, scarce any *Stars* appear, besides one of the third *Magnitude*, near to the right *Claw*, and 3 others of the fourth, 2 whereof are most noted, whereof 1 stands towards the North, the other towards the South.

The *LION* is adorned with divers bright *Stars*, 2 whereof are of the first *Magnitude*. That which is seen in his *Breast*, is called the *Lions Heart*, or *Regulus*; and that in his *Tail*, the *Lions Tail*. Besides these there are 2 other, the one in his *Neck*, the other in the utmost part of his *Back*; to which, if the next *Stars* in his *Loyns* be added, they, together with those of the *Heart* and the *Neck*, will represent the *Figure* of a long *Square*.

In the *VIRGINS* left *Hand* is an *Ear* of *Corn*, in which there is a *Star* of the first *Magnitude*, commonly called, the *Virgins Ear* of *Corn*. There are also other *Stars* of the third *Magnitude*, dispers'd all along the *Virgins Body*.

SCOR.

XIII. SCORPIUS, besides 2 Stars of the second Magnitude plac'd in the further part of his Claws, and 2 more of the third Magnitude in his Tail, hath another in the midst of his Body, called the Scorpion's Heart, plac'd between 2 Stars of the fourth Magnitude.

XIV. LIBRA consists of 2 very bright Stars, which are called the Scales.

XV. In SAGITTARIUS are 4 Stars more considerable, which being plac'd on his Right Shoulder, constitute a Trapezium or Table; besides 3 or 4 that do somewhat resemble a Bow: Beyond the midst of which, there is another of the third Magnitude, which represents the form of an Arrow.

XVI. The Chief Stars in CAPRICORN are 4 of the third Magnitude. There are 2 in his Tail that have a greater lustre than the rest; and two other in his Horns, the uppermost whereof hath a small Star joyned to it.

XVII. In AQUARIUS, the most conspicuous Stars are some of the third Magnitude about his Shoulders, with 4 others about his right Hand; the one whereof is, as it were, plac'd in the midst of a Triangle, constituted by the other 3. And there is another in his right Hand of the third Magnitude; besides which there are many other of the fourth Magnitude, and more especially one at the end of the pouring forth of the Water, which is of the first Magnitude.

XVIII. The Constellation PISCES consists of many small Stars; there being but few amongst them that are as big as those of the fourth Magnitude: And tho' these Fishes are at some distance from each other, the one in the Neighbourhood of Aquarius, under the Neck of Pegasus, and the other near to the Ram or Aries, under the Breast of Andromeda; yet they are tied together with a kind of loose Riband, which is also adorn'd with several Stars of the first Magnitude.

XIX. The Constellations without the Zodiac, are either Northern or Southern. The Northern, which appear in our Hemisphere, are 21; the particular account whereof here follows, beginning with that Constellation which is next of all to the Pole.

And this is URSA MINOR, the Lesser Bear; which consists of 7 Stars, 4 whereof represent a square Figure; whereof the uppermost in the Neck of the Bear, is of the second Magnitude; another lower than it, of the third; a third on the Back, of the fourth; and the last in the Back also, of the fifth. The hindmost and brightest of the other 3, is called the Pole-Star, because it is nearer to the Pole of any other.

URSA MAJOR, the Greater Bear, consists likewise of 7 Stars, whereof the 4 that represent a square, exhibit so many Wheels, and the other 3, the Beam of the Wain, and the Oxen or Horses that draw it; and therefore was called by the Ancients, *Plaustrum majus*, or the Greater Wain.

BOOTES, the Herdsman, or rather the Driver of the Oxen, called also *Arctophylax*, the Bearward, consists of many Stars of the third Magnitude, plac'd in the shoulder, back and knees of this Figure. But one of them is more famous than any of the rest, placed between his Thighs, on the rim or edging of his Coat, being of the first Magnitude, and is called *Arcturus*.

The DRAGON consists of many Stars, but none of them greater than those of the third Magnitude; only there are 2 in the Head of it, that are brighter than the rest.

The CROWN of ARIADNE, plac'd at the Right shoulder of Bootes, represents a half Circle, compos'd of 5 Stars; whereof 3 are of the fourth Magnitude, one of the fifth, and another of the second, which is called the Bright Star of the Crown.

ENGONASI, the Man, according to some Hercules, Kneeling, comprizeth several Stars all of the same Magnitude; of which one especially is more conspicuous in the Head of this Figure, for its being of an equal size, with another Star like it, found in the Head of Ophiuchus.

LYRA, the Harp, which by some is called the Falling Vultur, hath the most eminent Star of the first Magnitude, next to the Dog-Star; besides which it contains some few other Stars, 2 whereof are of the second Magnitude.

The SWAN is an illustrious Constellation within the Milky-Way, resembling the Form of a Cross; and hath a very notable Star of the second Magnitude.

CEPHEUS hath his Head pointing to the Swan, and his right Foot standing on the Tail of the Little Bear. It contains but few bright Stars, besides 3 of the third Magnitude, one in the Right shoulder, another in his Girdle, and a third in his Right knee.

CASSIOPEIA hath 5 Stars of the third Magnitude, over against the Great Bear, the least being in the midst of them; 3 of these are on the outside, one of them being called the Bright Star of the Chair; another upon her Breast, called Schedir; the third near her Flank; all which represent the Figure of a Triangle.

PERSEUS is plac'd between the Feet of Cassiopeia and the Bull, the most bright Star of which Asterism, that on the Back, is of the second Magnitude. It hath also another famous one of the third Magnitude, which being placed in the Head of Medusa in the Left hand of Perseus, is therefore called the Head of Medusa, and the other 4 are call'd Gorgons.

ANDROMEDA is an Asterism under Cassiopeia, on the Left-side of Perseus; very remarkable, because of 3 Stars it hath of the second Magnitude; one whereof is on the Left Foot, above the Triangle, the other in the Girdle, above the Fishes; the last in the Head, which is common to her and Pegasus.

DELTOTON, or the Triangle, consists of 3 Bright Stars of the fourth Magnitude, one whereof is at the top, and the other 2 at the Basis of it, with another Star of the fifth Magnitude, near to it.

AURIGA, the Wagoner or Wain-Driver, hath a Star of the second Magnitude in the Left Foot, where there is also another of the fourth Magnitude. But the most noted of them all is a Star of the first Magnitude very illustrious, on the Left shoulder, called Capra, the Goat.

PEGASUS, or the Flying-Horse, is a notable Constellation, by reason of a large square compos'd by 4 of its Stars of the second Magnitude. Besides which it contains other 3 of the third Magnitude, the one in the Knee, the other in the Neck,

Neck, and the third in the Opening of the Mouth, which is therefore call'd the Mouth of Pegasus.

16 The DOLPHIN, seen between the Constellation of the Colt and the Eagle, has 10 Stars, whereof 5 are of the fifth Magnitude: The other, except that which is in the Tail, do constitute the Figure of a Lozenge.

17 The ARROW hath 5 Stars, of which, that at the Point is of the fourth Magnitude.

18 The COLT is nothing else, but as it were the shadow of the Head of Pegasus, in which are seen 4 Stars, all of them of the fourth Magnitude.

19 The EAGLE is considerable for 3 Stars, representing the situation or position of Orions Girdle. The 2 that are at each end, are only of the third Magnitude; as likewise 2 others at the end of his Tail: The Star which is in the middle is of the second Magnitude, and out-shines the rest, being therefore call'd, the Bright Star of the Eagle.

20 SERPENTARIUS OPHIUCHUS, or the Serpent-Bearer, is a great Asterism; for its Head is near to the Head of Hercules; its Feet rest upon the Scorpion; the Head of the Serpent reacheth to the Northern Crown, and its Tail to the Eagle. Its greatest Star is only of the third Magnitude. Yet there is one of these that is very considerable by the right Ham, between the Scorpion and Sagittary, which in the Fourth year of this Century was accounted amongst the Great Stars.

21 The SERPENT of Ophiuchus, is famous for several Stars of the third and fourth Magnitude, in the middle Joynt of the Neck, next to that Hand in which Hercules holds his Club.

XX. The Southern Signs are 15 in Number, without the Zodiack.

The first is the WHALE, situate under the Fishes and the Ram, having a vast wide Mouth, in the midst whereof is a Star of the first Magnitude, the Bright Star of the Jaw-bone of the Whale; and hath another of the same Magnitude answering to it, in the midst of the Point of his Tail; besides other Stars over his whole Body, of the third and fourth Magnitude.

2 The ERIDANUS is a long and winding Asterism betwixt Orion and the Whale. The end of which, towards the South, is invisible to us.

3 The HARE, besides other of the Stars whereof it is composed, hath 4 of the first Magnitude, and other 4 smaller ones in his Ears.

4 ORION is a Constellation, adorned with many bright Stars. Of these, 2 principal ones are in his Shoulders, 3 in his Girdle, which are called Three Kings; 1 in his right Knee, and another in his left Foot, called Rigel.

5 The GREAT DOG hath not his equal for Brightness, and is commonly call'd Sirius, as being supposed to Dry all things. About his right Feet he hath some Stars of the third Magnitude.

6 The LITTLE DOG riseth before the Greater, and is, as it were, the Harbinger of his Rising. Besides the Star which is in his Neck, of the third Magnitude, he hath another Bright one in his Thigh of the second Magnitude, called Procyon.

7 The Ship ARGO hath but a few Stars that are conspicuous, except it be about the Mast. In its Helm is a very noted Star, called Canopus.

8 HYDRA, the Hydre, a Water-Serpent, is a long extended Asterism; for with its Head it toucheth the Claws of the Crab, and its Tail is near to Libra, or the Ballance. It hath a very bright Star in its Breast of the first Magnitude, called the Heart of the Water-Snake.

9 The BOWL, or Cup, is placed upon the Middle part of the Hydra, having some Stars of the fourth Magnitude, representing an half Round.

10 The CROW is very remarkable, by reason of the Table in it, consisting of 4 Stars, whereof 3 are of the third Magnitude, and another of the fourth.

11 The CENTAUR, besides 14 visible Stars, hath others that are not conspicuous to us; whereof 1 is of the first Magnitude, at the right Fore-foot of the Horse. In his hind Legs are 4 Stars, which represent a very remarkable Cross. The Uppermost and Lowermost are of the second Magnitude; but the Right and Left of the third.

12 The WOLF, or Wild-Beast, doth with his Head reach the middle part of the Scorpion; it hath no Stars bigger than of the fourth Magnitude.

13 The ALTAR, or Censer, is for the most part hid from us under the bending of the Scorpions Tail. It hath no greater Stars, than of the third Magnitude.

14 The SOUTH-CROWN hath one very notable amongst the rest, of the third Magnitude; and is the same which is called by some Uraniscus, or the Petty-Heaven.

15 The SOUTH-FISH contains many Stars, and those of the fourth Magnitude, under the left Leg of Aquarius. In its Mouth it hath a Principal one of the first Magnitude, called Fomabant.

XXI. Tho' the Constellations of the Zodiack, together with the North and South, are reduced to the Number of 48; yet we are to know that the Astronomers could not comprize them all into Figures, but were fain to leave some in the Intervals of them, which they called Unformed, as being comprehended in no Figure or Image.

XXII. The Astronomers also make mention of the Galaxy, or Milky-way, which is nothing else but a vast multitude of thick-set Stars, that by their weak Light represent the appearance of Milk in a clear Sky, as the Telescope hath informed us. Whereby ARISTOTLE is convinc'd of a manifest Error, who suppos'd the Milky-Way to be a Meteor; who yet therein is to be pardoned, because he wanted the Helps that we have to discern it better.

XXIII. We are to observe, that when that the Sun, or any Planet, is said to be in a Sign: As for Example, in the Ram, or in the Bull; the meaning thereof is, that it is plac'd under it, or that it intervenes, or is intercepted between our Eye and that Sign. For it is certain, that the Zodiack, and its Signs, are at a vast distance from the Planets. But this way of speaking hath obtain'd, because the Planets appear to us, as if they were in the Region of the fix'd Stars. For our unassisted Sight cannot discern which of the Stars are farther from, or nearer to us. Hence it is, that because we know that the Planets are nearer to us than the Stars, we understand them

to

to be so placed, as to be between us and the Signs. But the Stars that are without the Zodiac are said to be in that Constellation, or rather to belong to it, between which and the next Pole of the Zodiac they are placed.

CHAP. XXVI.

Of the Influence of the Stars, and of Judicial Astrology.

I.
The sense
of the
Question
stated.

IT is a Question frequently handled by the gravest Authors, Whether the Stars act upon these Inferiour Bodies; and whether the Things that happen here on Earth do depend on their Influences. Or to speak more plainly, Whether the Stars be the Cause of those Effects we see in this Sublunary World; or at least, contribute something to their Production. For the better understanding of this Question, it will be necessary to examine the Virtue and Power of the Stars, and thence gather their manner and way of acting.

II.
The Sun
influenceth
this sublu-
nary World.

There is no doubt, but that the Sun concurs by a real influx to the Production of Terrestrial Bodies; yea, if we give heed to his Virtue, we shall find him to be the only, or at least the Principal Cause of all things that are generated in the Earth; for the Growing of Plants, the Nourishment of Trees, the Ripening of Fruit, and the Springing of Corn, are all to be referr'd to the Sun, by whose Heat they are cherished, grow, and are brought to perfection.

III.
An Obje-
ction a-
gainst the
Virtue of
the Sun.

If you say, That many things happen in the Earth which cannot be imputed to the Sun; as Cold and Moisture, which require a Cause distinct from that of Heat. For how can Heat be conceiv'd to be the Original of Cold? Or, how can the Sun, who is of a fiery Nature, produce Moisture, since the Natural effect of Fire is to dry, and deprive a Body of all Moisture? And therefore the Sun can only be said to be the Cause of some particular Effects.

IV.
Answer.

I Answer, It is true that Cold and Moisture do not proceed from the Sun, as their productive Cause; yet doth not this contradict their proceeding from the Sun accidentally. For as his presence drives away the Cold, and suffers it not to prevail on the Earth; so his absence suffers it to prevail, and exposeth Terrestrial Bodies to its contraction. In like manner, tho' Moisture doth not descend from the Sun; yet because the same abounds in the Earth, and that the Sun doth not always elevate the same into Vapours, therefore he may be said to be an Accidental Cause of it.

V.
The Sun is
the General
Cause of
all Effects
produced
in the
Earth.

The Sun therefore is to be considered by us as a General or Universal Cause, which every where diffuseth its Beams; yet it happens by Accident, that he illuminates one part of the Earth more than another: As it is accidental to Fire, that this or the other thing comes near to it, to be heated and cherished by it, or not. And hence it is, that all that variety, which we see in Nature, doth not so much proceed from the Sun, as from the various situation and disposition of Bodies. For the reason why in one part of the Earth it is Spring, in another Autumn, in a third Summer, doth not proceed from the Sun as a Special Cause, but only as a General, the Sun being always the same, and equally diffusing his Heat. For that it is now, suppose,

Summer with us, by the Sun-beams falling more directly upon us; this is owing to that Part of the Earth wherein we live, whose situation is so directed towards the Sun, as to receive his Beams more directly, at the very same time that it is Winter with our Antipodes; to whom the Sun-beams are obliquely directed.

I know that some Philosophers refer the Cause of this diversity to the Planets, as supposing Saturn to be Cold; Mars, Hot; Venus, moderately Warming; Mercury, Various; the Moon, Cold and Moist. But these I take to be no more than meer Fictions, since we perceive no Cold from Saturn, nor Heat from Mars; and so from the other Planets: Because it cannot be, that we should feel or perceive any of these Qualities, but that at the same time all the other Inhabitants of the Earth must perceive the same, seeing that they are sensible of these Vicissitudes of Seasons, as well as of the Sun's Heat; and therefore these Changes depend on the various position of the Parts of the Earth. As we see, that the South-Winds, which produce Warm Weather in the midst of Winter; and North-Winds, which cause Cold in Summer, do not arise from the Aspects of the Planets, since the same Aspects are over the whole Earth, and yet we do not find the same Winds every where; so that they proceed only from the various disposition of the Regions of the Earth.

Neither do the Fix'd Stars seem to dispense any Influences to us here below, because their vast distance hinder them from producing any Effects here: For tho' by their Light they may put the subtil Matter contain'd in the Pores of the Air into motion, and by means thereof agitate other grosser Matter, which thereby may produce a sensible Effect; yet because we know of no other Virtue that is in them, whereby they might act upon these Inferiours, save only their Light, we cannot attribute to them any Effects, besides those that proceed from Light. And forasmuch as the Light of the Sun is incomparably greater than that of the Fix'd Stars, we are to attribute all Natural Effects to the Light of the Sun, as the General and Primary Cause of them.

This Opinion may be further confirmed, if we consider that the Fix'd Stars do not Rise and Set now at the same time as formerly; but because of their turning round from East to West, they Rise now almost a whole Month later than of Old: And yet the Seasons and General Changes that are in the World still observe the same Tenour, and correspond with the Sun's Course through the Zodiac. For the Dog-Days, by Example, or that great Heat, which in old Times was perceived about the midst of July, still continues about the same term, neither is changed to the midst of August, at which time the Dog-star, which they make the Cause of its Heat, doth now Rise. Neither can we suppose, that 6000 years hence, this Heat will be removed to the midst of November, at which time the Dog-star will then Rise. Besides, if the Heat we perceive in Summer be to be ascribed to the Dog-star, how comes it to pass that at the same time the said Star is almost 40 Degrees distant from the Sun? Since it might be rather expected it should display its Heat in the Winter, when it is conjoyn'd with the Sun, viz. about the 29th of October.

VI.
The Pla-
nets contri-
bute no-
thing to
any sublu-
nary Ef-
fects.

VII.
The Fix'd
Stars send
down no
Influences
upon these
Inferiour
things.

VIII.
The Fix'd
Stars do
not always
Rise and
Set at the
same time;
and yet we
find that
the General
Changes of
Seasons in
the World
keep the
same time.

IX.
The Cause
of the
great Heat
in Summer.

The Cause therefore of these great Heats is, because the Sun at that time sends down his Beams more perpendicularly upon us, and continues longer above our Horizon; and forasmuch as this perseveres for some Days after the Solstice, during which time new degrees of Heat are still added, it cannot be otherwise, but that the Heat during that time must be increased.

X.
The Moon
produces
no Effects
upon the
Earth.

Neither doth the Moon, tho' she be so near unto us, produce any Effects here below. I know that several Effects are attributed to her by some; as the Breaking or Splitting of Stones, and the increasing of Oysters, and other shell-Fish, at the Increase of the Moon, and their decreasing at the Wane of the Moon; as likewise that the Bones of Animals, at the Full-Moon, are full of Marrow, whereas at the New they are almost empty.

XI.
What is
the Cause
why Stones
are broken.

But all these Effects may be with more Truth attributed to other Causes, than to the Moon. For as to the breaking of Stones, the same may with more Reason be attributed to the Sun, than to the Moon; seeing it is certain, that some Stones, after many years lying expos'd to the Sun, have been calcined. And therefore seeing that the Sun's beams reach the Stones, as well as those of the Moon, it seems very reasonable that this Effect should rather be imputed to the stronger, than the weaker Agent.

XII.
The increase
or decrease
of Oysters,
doth not
proceed
from the
increase or
decrease of
the Moon.

So likewise it is a Popular Error to imagin, that Oysters and other shell-Fish, are bigger and fuller at some times of the Moon, than at others: For tho' they are sometimes bigger than at other times, yet is not this to be ascribed to the Moon, but rather to Chance, because they have not had sufficient Food, or because the tossing of the Sea hath forced them to some Evacuations. This is apparent in those Fishes which are taken in the same place, and in the same day: For those which are caught in a Net, and immediately taken out thence, are fuller Bodied and better Fed, than those which having been long kept up, have lost much of their flesh by striving to get out. The original therefore of this Error hath been, for that some have taken that to be caused by the Moon, which was merely fortuitous. And accordingly we find, that indifferently at any time some Oysters are found to be fat and full, and others, lean and poor.

XIII.
The Cause
why more
or less
Marrow is
found in
the Bones
of Living
Creatures.

And the same may be said of the Marrow that is found in the Bones of Animals: For several who have examin'd the matter, have found that there is no more Marrow in the said Bones, at any one precise time, than at another; but that the want or defect thereof sometimes is caused, by want of Food, or for that the Beasts have been tired by long Journeys before they were kill'd.

XIV.
What Ju-
dicial
Astrology
is, and of
how many
sorts.

Astrology is an Art, which foretells future things from the motion of the Heavenly Bodies, and their Aspects to one another. And is therefore called Judicial, because from these it judgeth of the Events of things. Astrology is twofold; the one is that Art, which from the position of the Stars at the time of Birth, judgeth of the Inclinations and Tempers of Men, whether they will be Passionate, Melancholy, Wise, Venereal, &c. because the Hour of their Nativity was accompanied with such or such Aspects of the Stars, which have a

Virtue of causing the Gall, Melancholy, or Spirits to abound. The second kind of Judicial Astrology is that Art, which from observing of the Horoscope, judges of Future Events, Children, Manner of Life, Marriage, Honours, Misfortunes, Losses, &c.

This Judicial Astrology was first cultivated by the Chaldean and Babylonian Philosophers, who not only affirmed that they could Foretell Future Events from the Aspects of the Stars; but also boasted that by them they could discover the particular Actions of Men, and the special Events of their Lives. But that both the one and the other of these are vain and false we prove as follows:

First, Because the Astrologers had no exact knowledge of the Virtues of the Stars, no not of such as were most Notorious. Secondly, Because they were ignorant of the Nature of most Stars, which might variously alter or hinder the operations of those Stars they knew. Thirdly, Because no sufficient Reason can be given, why Schemes for Nativities are erected from the point of Birth, rather than from that of Conception. Fourthly, Because the Astrologers themselves own, that they have no Principles whereby they might be informed, that the Stars have such Virtues as they assign to them, and that consequently their Predictions are not any deductions from Premisses, but the Dreams of Idle men.

Besides, how can they be assur'd of the certainty of the Events they pretend to guess at? Not by Experience: For who will conclude that it will lighten, for Example, upon the Kings entering into St. James's Park, because once it hapned so? Or that some King will dye at the Appearance of a Comet; because it hath been found, that upon the Appearing of a Comet some Prince hath died? And much the same Evidence the Astrologers have for their Predictions, since it is but once in many thousand years, that the Stars are found in the same position.

But let us grant the Astrologers, that some Changes have been observ'd to come to pass in certain places of the Earth, under such Constellations; yet can these only be of use to those Countries where they hapned: Seeing it is, most certain, that the same Fair weather, or Tempests, do not happen to all parts of the Earth at the same time: For we see it Rain in one part, whilst it is Fair weather in another. And thus the Dog-star, which most suppose to be Hot by Nature, and to be the Cause of the greatest Heat when it Riseth in July, is notwithstanding a sign of Cold to our Antipodes, and to those that live in the South-part of the Earth; because they at the same time that this Constellation Riseth, together with the Sun, and we feel the greatest Heat, experience the greatest Cold: Notwithstanding that it is then directly over their Heads, and sends down its direct Rays upon their Country.

Conclude we therefore, according as we have said at the Beginning, that the Sun is the General Cause of all the Effects that happen in this Sublunary World, forasmuch as by his presence he is the Cause of Heat, and by his absence of Cold; and that all the rest of the Stars or Planets, cannot be the Cause of any Alterations in these Sublunary things.

CHAP. I.

Concerning the Original of the Earth, its
Parts and Figure.

I.
What the
Earth is.

THE EARTH is a congested Mass
of the greater Particles of the
Third Element, having Irregular
Figures, and by Rest clinging to-
gether.

II.
The For-
mation of
the Hab-
itable Earth.

But, forasmuch as by the Name of EARTH,
we commonly understand the whole Globe which
we Inhabit, it will be a fit place here to speak of
its Original, and to describe how at first it might
have been form'd, had it so pleas'd GOD: Let us
imagine therefore, that it was made at first only
of the Matter of the First Element, being like
unto the Sun, tho' much less than it; and that it

had a vast and peculiar Vortex in the Center, whereof
it was seated: But that by the clinging together
of the less Subtil Parts of the First Element, they
were changed into the Matter of the Third Ele-
ment, which gathering together produced dark
Spots about its Surface, like to those that are con-
tinually generated about the Sun, and again dis-
solved. Upon the continual Diffolution whereof,
the remaining Particles of the Third Element,
being scatter'd through the Neighbouring Heaven,
made there a vast Mass of Ether, which being
afterwards greatly increased, caused the generation
of more compact Spots, which at last wholly cover'd
the whole Earth: Which Spots being no longer in
a condition to be dissolved, and many of them
lying heaped together, and the Force of the Vortex,
which contain'd the Earth being thereby diminish'd,

gave

gave occasion to the *Sun's Vortex* to swallow up the *Earth*, together with the *Spots*, *Air*, and all, which stop'd in that place where it now is.

III.
There are
three Re-
gions to be
distinguish'd
in the
Earth.

Figure
35.

Supposing the *Earth* in this *state*, we are to take notice of Three *Regions* in it: Whereof the *First* and *last* I seems to contain nothing but the *Matter* of the *First Element*, which is there moved like the *Sun*, and much of the same Nature; save only, that probably it is not so pure, because it cannot rid it self of that *Matter*, which the *Sun* continually casts forth, and of which *Spots* are generated. The *Middle Region* M, consists of a very dark and compact *Body*: For seeing that this *Body* was at first made up of very minute *Particles* (as at first appertaining to the *first Element*) joyn'd together, it seems probable that there could be no *Pores* in it, but such only as were so small, that they could only transmit those *striate Particles* with the other *Matter* of the *First Element*. And Experience witnesseth as much in the *Spots* of the *Sun*, which being of the same nature as this *Body* M; save only that they are much more thin and loose, do notwithstanding obstruct the passage of *Light*, which could not be in case their *Pores* were large enough to admit the *Globuli* of the *Second Element*. For seeing that these *Pores* were at first formed in fluid and soft *Matter*, they would also without doubt be strait and smooth enough, not to hinder the Action of *Light*. But these two *Regions* of the *Earth* do not much concern us, as being conceal'd from us. The *Third Region*, is that out of which all *Earthly Bodies* are formed, as we shall shew hereafter: At present we suppose nothing to be in it, besides a *vast Mass* or gathering together of the *Particles* of the *Third Element*, encompass'd with much *Heavenly matter*, whose nature we may easily understand from the manner of their *Primordial Generation*.

IV.
The Forma-
tion of the
various
Earthly
Bodies.

From what hath been said, we easily apprehend, that no great Change could happen in the innermost or middle *Region* of the *Earth*; but the *External part* of it, was capable of being formed into various *Bodies*. For at the first 2, then 3, and afterwards 4, with many other different *Bodies*, were to be made out of it.

V.
The Upper-
most Region
of the
Earth di-
stinguish'd
into two
Bodies.

Fig. 36.

And here, in the first place let us consider, that the grosser *Particles* of this *Third Region* being thrust down below the rest, by the force of the *Heavenly Globuli*, this *Supream part* of the *Earth*, here marked with the Letter A, is thereby distinguish'd into two different *Bodies*, represented by B and C; whereof the uppermost B, is of a loose contexture, fluid and pellucid; whereas the undermost is somewhat close, hard and opaque.

VI.
The For-
mation of
the Third
Body, be-
tween the
two former.

Again, because we find that the *Body C* was distinguish'd from the *Body B*, only by this means; because its *Parts* being prest downwards by the *Heavenly Globuli*, did cling together, we shall easily apprehend, that it was necessary that another *Body*, such as is that marked D, must have been generated between them. For the *Figures* of the *Particles* of the *Third Element*, of which the *Bodies* B and C consist, are very different, and may be here distinguish'd by us into 3 Chief General *Heads*; for some of them are variously divided and extended like the *Branches* of *Trees*, and these chiefly were those, which being driven down by the *Celestial matter* cling together, and compose

the *Body C*. Again, there are others that are more solid, and as to their *Figure*, are not all of them Round or Cubical, but of several *Figures*, like the small parts of *Rubbish*; and these, if they be somewhat great, sink down below the rest by the force of Gravity; but in case they be somewhat less, they continue mix'd with the former, and fill up the *Spaces* that are left by them. Lastly, there are some of a longish *Figure*, and without any Jettings-out like *Boughs*, but like long and even *Sticks*, which also mingle themselves with the former, where they find *Pores* or *Intervals* wide enough for them to enter, but do not readily cling or stick to them. Which being thus supposed, it will be obvious to believe, that when first the *Branchy Particles* of the *Body C* began to be entangled together, many of the *Longish* were intermix'd with them; and that they afterwards, whilst those being still more and more prest down, became more closely joyn'd together, got up above them towards D, and there constituted a *Body*, very different from the two other B and C. After the same manner as we see, that by Treading the *Earth*, in *Moorish places*, *Water* is squeez'd out of it, which afterwards comes to cover the *Surface* of it.

Now when some other *Particles* less solid than those of the *Body D*, fell down from B, they stuck to the surface of the *Body D*; and because most of them were *Branchy*, they by degrees clung together, and constituted the hard *Body E*, very different from B and D, which are fluid. Which *Body E*, at the first was very thin, like a *Crust* or *Shell* covering the *Body D*; but grew thicker in process of time, new *Particles* from the *Body B*, as likewise from D, joyning themselves to them.

We are likewise to consider, that it could so happen in process of Time, that a great part of the *Body D*, might be wasted, by which means a considerable *Space* F, might be left between D and E, which could not be fill'd up with any other matter, besides that out of which the *Body B* did consist, the thinnest *Particles* whereof, easily found a passage through the *Pores* of the *Body E*, into those places which were quitted by other thicker parts, which came forth from D.

Lastly, We may grant, that many *Cracks* might be made in the *Body E*, by the heat of the *Sun*; as we find that there are many *Cracks* in the *Ground* in *Summer time*, when it is parched by the *Sun*; and that these *Cracks* grow greater and greater, the longer that the *Drought* lasts: By which means its parts at last did so loosely hang together, that it was no longer able to hold up as an *Arch* between F, and B; but being broke to pieces, by reason of its *Heaviness* fell down upon the *Surface* of the *Body C*; and forasmuch as that *Surface* was not broad enough, for to receive all the *Fragments* lying together, so as to keep the same situation they had before, some of the said *Fragments* were forced to lye shelving one upon another. As for Example, If we suppose that in that part of the *Body E*, which this *Figure* represents, the chief *Crack* or *Slits* were so disposed in the places 1, 2, 3, 4, 5, 6, 7, that the two *Fragments* 2, 3, and 6, 7, should fall a little before the rest, and the ends of the four other *Fragments* 2, 3, 5, and 6, before the opposite 1, 4, and 7; as also the End 5, of the *Fragment* 4, before the End V of the *Fragment* V, 6, there is no question but

but they would be rang'd upon the Surface of the Body C, in the same manner as they are delineated, viz. so as that the Fragments 2, 3, and 6, 7, would be joyned next to the Body C, and the other four lye shelving on their sides, the one leaning upon the other, &c.

Further, if we consider that by the Body B, and F, here, the Air is to be understood; and by C, an inward very thick Crust of the Earth, from whence Metals are generated; by D, the Water; and lastly by E, the outward part of the Earth, which consists of Stones, Clay, Sand and Mud; we shall easily understand by the Water arising above the Fragments 2, 3, and 6, 7, the Sea; by other Fragments that are but a little leaning, and not covered with any Waters, as 8, 9, and V X, great Plains; and by others that stand more upright, as 1, 2, and 9, 4 V, Mountains. We shall also take notice, that when these Fragments by their own weight thus fell down, their extremities or ends forceably dash'd against each other, which made them fly into many less Fragments; which made great Stones on some Sea-shoars, as at 1; and several tops of Mountains, partly very High, as at 4; partly Rising only, as at 9 and V; as also Rocks in the Sea, as at 3 and 6.

XI.
The Earth
is a Round
Body.

As to what belongs to the Figure of the Earth, it may be Mathematically demonstrated that it is Spherical; but forasmuch as Mathematical Demonstrations seem obscure to those who are ignorant in the Doctrin of Dimensions, it will here be sufficient to prove it to be so: First, Because its Particles are equally prest on all sides by the Heavenly Matter that surrounds it. Secondly, Because the Sun, who is at a great height above us, doth not enlighten all the Parts of the World at once, but first vouchsafes his Light to the Eastern Inhabitants, and afterwards to the Western; in which communication of his Light he observes this proportion, that those who live 15 Degrees nearer to the East, perceive his Light one hour sooner; and those who live 30 Degrees nearer, two hours; and so for the rest, observing the Proportion of 15 Degrees for each hour. Which could not be so, if the Earth were not of a Round figure.

XII.
The same
proved
from the
position of
the Stars.

The situation of the Stars also confirms this. For those Stars which are about the North Pole are always in sight; whereas those that are about the South Pole do not appear, except we move so far towards the South, as to be in the midst between both Poles: In like manner the Sun doth sooner Rise and Set to those that live more Eastward, than to those that live Westward, as appears by an Eclipse, which was seen by us at Midnight; and by those that liv'd Eastward, not till after 3 a Clock.

XIII.
The Moun-
tains are
no Argu-
ment a-
gainst the
Round
Figure of
the Earth.

Neither is the Inequality of the Surface of the Earth, by reason of High Mountains and Deep Valleys, any Proof against its Roundness: For the Earth is not Mathematically Round, as an exact polish'd Globe, but Geometrically; inasmuch as all these Inequalities, compar'd with the Compass of the Earth, are no more an obstacle to its Roundness, than the unevenness of the Rind of an Orange spoils the Roundness of its figure.

XIV.
What we
are to un-

derstand the Earth it self, but the Water also which covers a great part of it; seeing that the Parts of

both of them tend to the same common Center; and because the Surface of the Sea is continuous with that of the Earth; so that to those who Sail North or South, or Inhabit Eastward or Westward, the same Quarters of Heaven appear, or disappear. Which is an evident Proof, that the Surface of the Earth is not a level or plain, since those that set Sail do find, that the swelling Roundness of the Sea hides the Earth from them, and at last makes it altogether disappear.

Accordingly GASENDUS well infers, that no two Plumb-Lines, or Perpendiculars, are exactly Parallel; and consequently, that no two Walls built by a Plumb-Line, are such, tho' they appear so to the Eye: For seeing that all Perpendiculars fall upon the Convex surface of the Earth, they must needs meet in the Center, in case we should suppose them to be drawn on at length, and consequently cannot be parallel.

Forasmuch as the Semidiameter of the Earth is a Measure, whereby we discover the magnitude and distance of the Stars; we are to take notice that one Degree of a great Circle doth contain 60 Miles on the surface of the Earth: By which Number, if we multiply the 360 Degrees that are in a whole Circle, we shall find that the Compass of the Earth consists of 21600 Miles. Besides, we are to observe, that when a Circle is divided into 22 parts, its Diameter contains 7 of them, and its Semidiameter 3 and an half: So that the whole Compass hath the same proportion to the Diameter, as 22 to 7. Wherefore the Diameter of the Earth consists of 7200 Miles, and the Semidiameter 3600 Miles.

From the Description we have already given of the Earth, it follows also that it must be Hard and Dry: For the Dryness and Hardness of any Body proceeds from the Resting of its Parts. As also, that it must be Cold: For seeing that its Parts have either but a very weak, or else no motion at all, neither can they be conceived to have any heat to speak of. It is necessary also that it should be Heavy: For seeing its parts have less Force than others, to recede from the Center of the Vortex wherein it is contain'd, they must needs be driven down towards it. So likewise it is Opaque, and reflects the Light it receives; by reason of the Interruption and manifold Windings of its Pores, not exactly answering to one another.

There are 4 kind of Pores, that are found within the Earth. The First whereof are such as are extended in length, but with wavings and turnings this way and that way. The second are strait Pores, whereof some have a hollow Surface, but rough and rugged, and others smooth and even. The third kind are those, that run into one another, and whereof one has often communication with many other Pores, upon which account we may compare them to the Branches of Trees. And lastly, the fourth kind of Pores are such, as are somewhat like Screws.

But tho' we have here deduced all the Pores of the Earth to four kinds; yet we allow that there may be infinite variety in one and the same kind, so that it may be there are not two Pores of one and the same kind, that are altogether like one another.

A a a

CHAP.

CHAP. II.

*The Earth is moved by the fluid Heaven,
that encompasseth it round.*

I. The Common People suppose the Earth to remain immovable in the midst of the World.

The Common People are not more obstinate in any Persuasion, than they are in that of the *Earth's Immobility*; for they cannot imagine, that that which is the foundation and support of all things, should be moved; or that a *Body* of such prodigious Weight and Bulk should be carried about by another. Hence it is they believe, that the *Sun* and *fix'd Stars* are whirl'd round about us, and that the *Earth* rests immovable in the midst of the *Heaven*. Indeed our *Eyes* are not wanting to confirm this Persuasion; for we see that the *Stars* turn towards us from the *East* to the *West*, and that the *Sun* after the same manner insensibly approacheth to us.

II. We must not be too apt to trust our Senses.

But we ought to remember, that we must not too much rely upon the report of our *Senses*. For in this case it is with us, as with those that are in a *Ship*, who think that the *Shoar* departs from them, when indeed they themselves do depart from the *Shoar*. For to make a thing appear as if it were moved, it is all one, as *ARISTOTLE* saith, *Whether the Motion be in the Spectator, or in the thing that is moved*. Wherefore neither must it seem strange to us, who are carried about with the *Earth*, from whence we see nothing but the *Roof of Heaven*, and the *Stars* in a manner resting in their several *Stations*, that they do seem to draw near, pass by, and depart from us, the *motion* of the *Earth* being most steady and even. This is the *Reason*, that whilst Men look upon the *Earth*, they cannot conceive it to be moved; but when they turn their *Eyes* to any other *Object*, with regard to which the *Interval* is either increased or diminished, then indeed it seems to be moved: But our *Sight*, or rather our *Mind*, is more apt to ascribe it to the thing seen, tho' it be at rest, than to the thing that is moved, which it finds to be at no distance from it self. But that we may not seem to assert this without any grounds, we will enquire, Whether the *Earth* in it self have any *Repugnance to motion*; and if we find it hath not, Why should not we conclude that it is moved?

III. The Objections that are made against the Motion of the Earth.

Two things are only alledg'd against the *Motion of the Earth*, viz. its *Bulk*, and its *Weight*. For they Object, that all the parts of the *Earth* tend to the *Center*, where they are kept by the force of their *Gravity*. As we see that *Stones* and *Metals* rest in their several places, whence they cannot be removed without force, by reason of the propension they have to the *Center*. But that this Reason is not conclusive, appears from hence, that round *Bowls* or *Bullets*, made of *Iron* or *Steel*, are by a small Force made to trundle along a *Plain* or *Level*. *Stones* therefore and *Metals* continue in their places, not because they strive to tend towards the *Center*, but because they are firmly joyned to the *Bodies* whereon they lye; which Impediment is not to be found in the *Earth*, as being surrounded with the *Fluid Heaven*.

IV. There is no inward

Besides, we know that there is no *Inward Gravity* in the *Earth*, seeing that all *Gravitation* is caused by the *Heavenly Globuli*, which drive Ter-

restrial Bodies towards the *Center*; so that if we should suppose all the Space about the *Earth* to be fill'd with such *Bodies*, as did neither promote nor hinder the *motion* of other *Bodies*, and the *Earth* to be turn'd about its *Axis* in 24 *Hours*, all its *Parts*, which did not very closely stick together, would fly away on every side; as we find that *Sand*, which is cast into a *Whirlpool*, is every way dissipated. And accordingly we may rather account the *Parts* of the *Earth* to be *Light*, than *Heavy*.

Neither do I see what else can be understood by the *Heaviness* of the *Earth*, than a *Quality* whereby *Bodies* tending towards the *Center* of the *Earth*, have a tendency also to lye closer and cling together. Now such a *Heaviness* cannot hinder the *Earth* from being whirl'd about with the *motion* of the *Heaven* that surrounds it; no more than a *Company of Men*, being in a *Boat* that is whirl'd round, could hinder their turning round, by their mutual embracing and holding fast to one another.

Neither can the *Bulk* or *Magnitude* of the *Earth* hinder its *motion*: For the *Bigness* of a *Body* doth not deprive it of *Mobility*, which is a *Property* of all *Bodies*, and cannot be removed from them, except we should own all *motion* to be violent.

We must conclude therefore, that the *Earth* can be carried round by the *Celestial matter* that surrounds it. For seeing that according to our *Supposition*, the *Vortex* of the *Earth* hath been swallow'd up by that of the *Sun*; and that by this means the *Earth* hath been thrust down to that place where it now is, where it is surrounded with the *Fluid Heavenly matter*, always turning round, it cannot be otherwise but that the *Earth* must be carried about with it. This is clear of it self. Secondly, from the *Nature* of the *Earth*, which being a *Planet*, must not only be carried round by an *Annual motion*, in the surrounding *Celestial matter*; but also by a daily *Circumvolution*: For the *Earth* having formerly been a *Star*, may easily be conceived to have retain'd the *motion* it had before; and seeing that the *subtil Matter* in its *Center* doth turn round, it communicates that *motion* to the other *Parts* of the *Earth*, and makes the whole to turn round likewise.

But you'll say, What resemblance is there between the *Earth* and the *Planets*, seeing that it is the meanest of all other *Bodies*?

Yet for all this, if we consider the *Form* and *Nature* of the *Earth*, we shall meet with several *Arguments* to persuade us, that it is a *Planet*. For it is very like to the *Planets* in its *bulk* and *bigness*. Its *figure* also and *situation* prove the same; for it is as round as they are, and hangs pois'd in the midst of the *Air*. So also like them, it wants *Light* of its own, and shines only with a borrowed *Refulgency* from the *Sun*: And lastly, It is subject to the same *Appearances*, *Aspects*, *Directions*, *Stations*, *Retrogradations*, &c. For to pass by its various *Reciprocations* with the *Moon*, whatsoever *Mercury* and *Venus* do appear to the *Earth*, the same doth the *Earth* appear to *Mars*, *Jupiter*, and *Saturn*: And as *Mars*, *Jupiter*, and *Saturn* appear to her, so doth she appear to *Venus* and *Mercury*. Wherefore since the *Planets* are moved, why may not we conclude that the *Earth*, so far as it is

Heaviness in the Earth.

V. The Heaviness of the Earth cannot hinder its Motion.

VI. Its Bulk is no obstacle to its Motion.

VII. The Earth is turn'd round by a yearly and daily Revolution.

VIII. An Objection against the Earths being a Planet.

IX. The Properties of a Planet do belong to the Earth.

is like them, must likewise move about its own *Axis*, and about the *Center* of the *Universe*. How does it appear then, that the *Earth* is the meanest and most ignoble of all *Bodies*; but only from that mistaken Opinion, that the *Matter of Heaven* is something that is *Divine*, and that the *Earth* is nothing else but the very Sink of the *World*? What can hinder the *Earth* from being as Noble a *Body* as *Venus*, *Mercury*, or any other *Planet*?

X. According to Tycho's Hypothesis, the Earth is moved most of all. This Opinion will not seem strange to those that follow *TYCHO BRAHE*; for upon examining of his *Hypothesis* they will find, that he attributes more *Motion* to the *Earth* than we do. For supposing the *Earth* to be immovable, the *Heaven* and *Stars* must whirl round it in 24 hours; but this cannot be done, except that the Parts of the *Earth* be translated out of the Neighbourhood of those Parts of the *Heaven* which they touch; and forasmuch as *Motion* is nothing else than such a *Translation*, we may well conclude, that according to his *Hypothesis*, a *motion* must be attributed to the *Earth*. Yea, if we consider rightly of the *Matter*, we must conclude that the *Earth* is more moved than the *Heaven* it self; forasmuch as the *Earth*, according to its whole *Surface*, doth recede from the *Body* that surrounds it; whereas the *Heaven* only removes according to its hollow *Surface*, which is very little if compar'd with its *Convex Surface*. And thus according to *TYCHO*'s *Hypothesis*, there is an evident Reason for attributing a *motion* to the *Earth*; whereas the Reason whereby he attributes *Motion* to the *Heaven*, and *Rest* to the *Earth*, is altogether uncertain, and forged by his own *Imagination*.

XI. The Motion of the Earth produces no diversity of Aspect in the fix'd Stars, because of their vast distance. You'll say, If the *Sun* has its position amongst the fix'd *Stars*, and the *Earth* be moved round it, it is necessary that the *Earth* must at some times be nearer to them, by the whole Space of its *Orb*, than at other times; but the *Appearances* make out no such thing to us.

To which I Answer, That this Difficulty will vanish, if we consider the vast Distance that is between us and the fix'd *Stars*, which is so very great, that the whole *Orb*, which is describ'd by the *Earth* about the *Sun*, is but a *Point* compared with it. Which tho' it may seem to be incredible to those, who are not used to consider the wonderful Works of *GOD*, and who look upon the *Earth* as the chiefest part of the *World*, and the *Habitation* of *Man*, for whose sake all other things were made: Yet can it not seem so to *Astronomers*, who are well acquainted with these things.

XII. The Globe of the Earth is of an imperceptible Magnitude, when compared with the vast Compass of the Starry Heaven. From hence also we may easily answer the Objection of some *Astronomers*, alledging, That if the *Earth* were not in the midst of the *World*, the whole *Hemisphere* could not appear to us, or the one half of the *Heaven*, and especially of the *Zodiac*, which always contains 6 *Signs*. For these Men do not consider, that the whole *Earth*, compar'd to the *Heaven*, is of an insensible Bulk. Which thing *PYTHAGORAS* and *COPERNICUS* do not only affirm concerning the *Earth*, but also of the *Annual Orb*, compar'd with the *Heaven* of the fix'd *Stars*: For they assert, That 2 *Plains*, whereof the one being drawn through the *Sun*, the other through the *Surface* of the *Orb*, as *Horizontal*, would appear to meet together, because of the vast *Distance*: So that by that time they reach the *Heaven*, notwithstanding

that they are terminated at *Circles* so greatly distant from each other, as is the *Sun* from the *Earth*, they will seem to end at the same indivisible *Point*; neither doth the amplitude of the great *Orb*, hinder us from seeing the whole *Hemisphere*, and whole 6 *Signs* of the *Zodiac*.

In the second place you'll Object, That it hath been asserted in the *General Physicks*, that a *Body* which is turn'd round, doth endeavour, as much as in it lies, to recede it from the *Center*: How then comes it to pass, that *Castles* and *Steeple*s are not cast off into the *Air* by this *Circular motion* of the *Earth*?

It is Answered, That all the Parts of the *Earth* are on all sides prest down towards the *Center*, and hindered from flying loose and being scatter'd abroad: For the *Heavenly Globuli* moving by right *Lines*, or such as little deviate from them, drive with great force against the *Earth*; and thus thrusting all its Parts towards the *Center*, hinder it from flying out towards the *Heaven*: For seeing that the *Heaven*, which lies between the *Earth* and the *Moon*, is much more swiftly carried about the *Earth*, than the *Earth* is carried about its *Axis*: And since the *Particles* whereof the *Heaven* consists, are most fluid and variously agitated in *Right Lines*, or approaching thereto, they with great force strike against the *Earth*, by which means all the parts of the *Earth* are compress'd and thrust towards the *Center*.

CHAP. III.

The Earths Motion established by other Arguments.

I. Forasmuch as it is evident from what hath been said already, that the *Earth* of it self hath no repugnance to *Motion*; and that neither its Bulk, or *Heaviness*, can hinder it from being carried about by the fluid *Heaven*: It remains now that we superadd some *Reasons*, which have not only induced our Modern *Mathematicians*, but also the *Ancients*, to favour this Opinion.

But before I enter upon these *Arguments*, I would desire such as are free from Prejudice, to contemplate the vast extension of the *Heavens*, and compare the same with the small Bulk of the *Earth*, which is so many Thousand times less: (For even the Common Opinion admits the *Circumference* of the *Firmament* to exceed that of the *Earth* 50000 times.) Next, let them consider the swiftness of that *Motion*, which we must necessarily allow to those high *Bodies*, if we suppose them to be whirl'd about the *Earth* in the space of 24 *Hours*. Which being attentively consider'd, I question not but they will be more inclin'd to think the *Heavens* immovable, and that the *Earth* by its *Diurnal motion* is turn'd round the *Sun*, than that the whole *Universe* is snatch'd round about it, with a swiftness that is altogether uncomprehensible.

For the *Mathematicians* do allow, that the fix'd *Stars* are distant from us 14000 *Semidiameters* of the *Earth*. And since, according to *ARCHIMEDES* his Computation, the *Semidiameter* of the *Earth* consists of 859 *German Miles*, every one of which contains 4000 *Geometrical Paces*, or 20000 *Foot*, the *Circumference* of the *Sphere*

XIII. How it comes to pass, that this Motion of the Earth, doth not overturn Houses and Buildings.

XIV. The Answer.

I. The Earth hath no Repugnance to Motion.

II. The vast Extension of the Heavens, and the Liveliness of the Earth, are to be well consider'd.

III. The Motion of the Stars is incredible.

of the *fix'd Stars* will be of 75592984 German Miles. And seeing all this Space must be run over in 24 hours; in 1 hour the 24th part of it must be dispatch'd, that is, 3149066 German Miles; in the 60th part of an hour, or a first Minute, 52494 German Miles; in a second minute, that is, the 3600th part of an hour, 874 German Miles, that is, 32496 Italian Miles, or 3496000 Geometrical Paces, or 174900000 Foot, which is inconceivable in so short a Space.

IV.
The Earth's Motion, proved by an Argument drawn from the Ptolomaick Hypothesis.

A strong Argument for the Earth's Motion, may likewise be drawn from the PTOLOMAICK Hypothesis. For according to it, the Heavenly Bodies are moved more slowly or swiftly, according to their Bulk; they that are less in Bulk performing their Revolution in less time, than those that are of a greater Bulk. Thus Saturn, the highest and biggest of all the Planets, takes up almost 30 years in running through his Orb; Jupiter 12, Mars 2; and so of the rest, according as the Orbs they are to run over, are nearer or further from the Earth: But if we suppose the Immobility of the Earth, all this Order must be overthrow'n, since not only Saturn, but all the Intermediate Planets between him and the Earth, must be hur'd about in 24 hours: All which things are contrary to the Phenomena.

V.
The Motion of the Earth, makes for the Beauty and Order of the World.

But supposing the Earth to be moved, all these things are sav'd, and the comely Order of the Universe preserv'd and establish'd. Seeing that we may proceed from the Earth, to those Bodies that are more slowly moved, without any confusion, till we come to the Heaven of *fix'd Stars*. Or if any one should assert the *fix'd Stars* also to be moved, thence will follow another Absurdity, viz. that their Motions will be unequal. For some of them that are in the Greatest Circles will be most swiftly moved, and others in the least Circles, with a very slow motion, according as the said Circles shall be further from the *Ecliptick*, and nearer to the Poles. Now what can be more absurd, than to suppose Bodies to be moved at the remotest distances from the Center, and yet to assign the least Spaces to their motions?

VI.
If the Earth be immovable, there must be two contrary Motions in the Heavens.

Moreover, all those who are of the contrary Opinion, hold, that the Determination of a motion towards one part, and its meeting of another Body, resting, or otherwise moved, are contrary to one another: Now supposing that the Heaven is moved, we shall find divers motions in it, one from East to West, and another from West to East. For the Heaven, according to them, is most swiftly whirl'd towards the West; and the Planets from West to East; which two motions are Diametrically opposite. Now, it is impossible for one and the same Body to be carried divers ways by contrary Motions: For if a Body be carried from East to West, it cannot at the same time be carried from West to East.

VII.
These Difficulties are removed by the Motion of the Earth.

But what still more surpasseth our Apprehension is, How it is possible that whilst the Heaven is with such incredible swiftness hur'd about, the Planets should in spite of it perform their Courses in a quite contrary motion to it; especially seeing that their motion, compared with that of the Heaven, is very slow, and therefore may be easily overpower'd by a stronger motion. But by attributing a Motion to the Earth, all this contrariety of motions ceaseth, and we have no more than one

motion, viz. from West to East, which way the Earth and all the Planets are carried.

The great Force also of the Motion of the Heavens, asserted by the Followers of PTOLOMAEUS his Opinion, is a strong Argument to prove the Diurnal Circumvolution of the Earth; for they must allow it to be so powerful, as to whirl about with it not only the Planets, but also the *fix'd Stars*. Now if it be so that all Inferiour Bodies are forc'd to follow the motion of the Highest Heaven; and that the Element of Fire, and a great part of the Air, cannot resist its motion, how is it possible that the Earth that hangs in the midst of the Air, and is indifferent to Motion, or Rest, and surrounded with fluid Matter, should for all that alone remain immovable, and resist so vast a Force? This, according to my sense, seems utterly inconceivable; for by what Ropes or other Holdfasts, is it kept immovable in this *Aethereal Ocean*? For altho' the Heavenly Matter be liquid, and doth not push against other Bodies, with as much force as hard Bodies do; yet neither can it be denied, but that the motion of fluid Bodies, when determin'd to some one part, doth carry along with them whatsoever Matter is contained in them, how solid or compact soever it may be, except it be detained by some outward Force. As we see that great Stones, by the strong Current of Rivers, are carried along to a vast distance, except they be stop'd by the unevenness of the Bottom, or some other Obstacle. Now all these Difficulties vanish by ascribing to the Earth, which is a very little Body, yea, imperceptible, if compar'd with the Universe, and unable to cause any Change in the World, a motion round its own Center.

Moreover, what shall we assign to be the Cause, that keeps the Earth immovable? Is it by some Force? But where shall we look for this Force? or what is it? Is it a Natural Force, depending on the Divine Order and Constitution, settled in the first Creation, and consequently the ordinary Providence of GOD? Or is it an immediate Hand of GOD? It cannot be the ordinary Power of GOD: For the Order of Nature is this, that where Bodies that are near and far off, are hurried away by another Body, there also that which intervenes between those that are near and far off, must be carried about also, except something hinder it. Let us suppose Lines to be drawn from the Sun through the Earth and Planets; by which Lines we are to conceive the Sun-beams to be diffused, according to TYCHO, that by them he may carry about with him the Upper and Lower Planets; if therefore he snatcheth the superiour Planets along with him, must not he of necessity do the same for the Earth, which is in the midst between them? Neither can this be said to be done by the immediate Power of GOD, since TYCHO himself never thought fit to have recourse to any such Power, for the making out of his Hypothesis.

The Light of Nature also seconds our Opinion; for those Bodies are supposed to be of different Natures, which are endued with different Affections: Thus Lucid and Opake Bodies are distinguish'd in their Composition, because they have distinct Properties. Wherefore seeing that the Planets, of whose number the Earth is, are solid

VIII.
Tis incredible that all the Heavens should be moved about the Earth, and that it should be unmoveable.

IX.
It is also contradictory to the Order of Nature.

X.
The Sun being the great Lamp of the World, it would be absurd to conceive it plac'd in a Corner.

and destitute of all *Light*; it is necessary that the *Sun* and *fix'd Stars* should continue unmoved, and that the *Earth* and the rest of the *Planets*, should move round him, to partake of his *Light*. For as it would be absurd to place a *Light*, that is to enlighten a *Church*, in some *Corner* of it, and not in the *midst*: So the *Sun* being design'd to be the *Great Light* of the *Universe*, by which other *Bodies* were to be illuminated, it was to be placed in the *Center*, and not in one of the *Sides* of it. And accordingly we must conclude, that the *Sun* stands still, and that the *Earth*, with the rest of the *Planets*, are carried round him.

XI. Besides, I cannot conceive what Reason some Philosophers could have, to maintain the *Earth's* Immobility, seeing that the same Effects follow, whether its motion be allow'd or deny'd. For the *Sun* seems to us to run through the *Zodiack* after the same manner, notwithstanding that he rests in the *Center* of our *Vortex*: For wheresoever the *Earth* is, the *Sun* being look'd upon from it, will always hide that *Sign*, in opposition to which the *Earth* is placed. Thus when the *Earth* is in *Libra*, the *Sun* is seen in *Aries*; and when the *Earth* passeth from *Cancer* to *Leo*, the *Sun* is seen to pass out of *Capricorn* into *Aquarius*.

XII. For seeing that no relation can be fixt between *Bodies* that are in motion, and it is necessary that some be moved, and others stand still, that we may be able to form some respect between them: The same Appearances happen to us, whether we suppose the *Earth* only to be moved, or the *Heaven* with the *Circumambient Bodies*; forasmuch as by this means the Relation only of a *Body* moving and at rest, is varied, the same effect being indifferently produc'd by either of them, as to us. Now this being supposed, it will not be easie for any one to believe, that *Nature*, which always proceeds the most short and compendious way, should have chosen to perform that by the unconceivable motion of so many vast *Bodies*, which she might, without all that ado, have brought about by the alone motion of the *Earth*.

XIII. These and other like Arguments, which I might alledge, are sufficient, as I suppose, to prove that the *Earth* moves, at least to those who listen to Reason, rather than Authority; especially if they consider, that the *Globe* of the *Earth* is turned round together, with the Neighbouring *Bodies* of *Water* and *Air*. For as the *Water*, as hath been said already; so likewise the *Air* makes a part of the *Terrestrial Globe*, and may be conceived to have the same respect to the *Earth*, as the *soft Down* that grows upon a *Body* hath to it.

CHAP. IV.

The Objections answer'd, which by ARISTOTLE and others, are framed against the Motion of the Earth.

I. AS *Lucid Bodies*, compar'd with such as are *Opaque*, do thereby appear the clearer; and as the *Sun* shines brighter, when newly got from under a *Cloud*: So I question not, but that this Opinion concerning the *Earth's* motion, will appear more plausible by a Refutation of the Objections that Adversaries make against it. Amongst those who oppose this Opinion, ARISTOTLE is the

Chief; a Man of a great Wit, and fit for the Contemplation, not only of *Earthly*, but *Sublime things*: Who 'tis like, had he liv'd in these our days, would either have been of our Opinion, or at least have better refuted the Arguments, which are brought to overthrow the Stability of the *Earth*.

The First Argument he brings against us is, That this Circumvolution of the *Earth* is not a *Natural*, but a *Violent motion*; because it is repugnant for that to agree *Naturally* to any thing, that doth not agree to all its parts likewise. Now it is evident that the Parts of the *Earth* do not move so, for they are carried in a *strait Line* to the *Center*; wherefore *Circular motion* cannot be said to be *Natural* to the *Earth*, and therefore much less to be everlasting.

This Objection is easily answer'd, by saying, That the word *Violent* doth not at all belong to *Natural things*, forasmuch as they are indifferent to *Motion* or *Rest*; and it is no less *Natural* for *Bodies* to be moved, when they are push'd forwards by an *External Agent*; than it is for them to rest, when they are not push'd out of their places. It belongs only to our Will to suffer *Violence*, when any thing is done that is contrary and adverse to it. But let us grant that *Violence* may be attributed to *Bodies*, and that there are certain Inclinations in things, by which they prosecute the Ends they are design'd for; yet cannot we conclude thence, that the *Earth* is moved against *Nature*, because its parts are moved downwards by a *strait*, and not by a *Circular motion*: For this is to be understood of the parts of the *Earth*, separated from the rest of the *Globe*; and thus consider'd, it is not necessary that they should be in all things like unto the whole: No more than it is necessary, that all the *Particles* of the *Earth* should be round; or every part of a *Circle*, make a *Circle*, because the whole is Round, and the motion of the whole constitutes a *Circle*: But only that the parts of the whole be moved together with it; and like as the *Globe* of the *Earth* is whirld about in 24 hours, so all the parts that compound it, be in the same Space carried about its *Center*.

Which Motion may be no less Everlasting to the *Earth*, than any other motion; yea, and more too, if we attend to the Nature of *Strait motion*. For it is certain, that the *Earth* cannot move for ever upwards or downwards: But what can hinder that a *Body* may move Round continually, supposing the same cause that produceth it at first, to persevere? Wherefore, according to our Principle we are to assert, that no force or violence is to be found in its *Nature*; and that it is no less natural for *Bodies* to move Round, than to move in a *strait Line*, upwards or downwards, or any other way whatsoever.

The *Heaviness* of *Bodies* seems of all other things to be most contrary to the Circumvolution of the *Earth*. For *Heavy Bodies* do from on high, fall to the *Earth* by a *strait Line*: Now supposing this *Circular motion* of the *Earth*; how can it be, that a *Stone* let fall from the Top of a *Tower*, should fall down plumb to the Bottom of it, when in the mean time that the *Stone* is falling down, the *Earth* that bears the *Tower* moves many Cubits; and therefore the *Stone*, in case the *Earth*

II. Aristotle's Objection, drawn from the Nature of Natural and Violent Motion.

III. The word Violent doth not belong to Natural things.

IV. Nothing hinders, but that the Motion of the Earth may be Everlasting.

V. The second Objection, from the Heaviness of Bodies.

were moved, would not light at the foot of the Tower, but a good distance from it, which is contrary to daily experience.

VI.
A Stone
falling
down from
the top of a
Tower, is
carried by
a twofold
motion.

This *Objection*, tho' accounted of great weight by our *Adversaries*, is nevertheless easie enough to be answered, if we consider, that in every *Heavy Body*, besides its *motion downwards*, there is another imprest upon it, from the *Earth*, whirling round about its own *Axis*, whereby not only it self, but the *Bodies* that are about it, are carried along. There is therefore a twofold motion in a *Stone* that falls from a *Tower*, the one a *straight motion*, whereby it falls down to the *Ground*, the other a *circular*, whereby the *Earth* is carried along with the *Celestial matter* that surrounds it; and therefore it is not necessary that a *Stone* fallen down from a *Tower*, should fall at a distance from it, since both of them are carried about with the same swiftness, and the *Stone* cannot but fall plumb down at the foot of the *Tower*. For it is no contradiction in *Philosophy* for one motion to be compounded of a straight and circular. *ARISTOTLE* himself owns as much, when he attributes to the *Fire* a *straight motion*, by which it is carried upwards; and a *circular*, in which it is carried about the *Earth* by the *supream Heaven*. A *Stone* therefore falls plumb down to the *Earth*, because with respect to the *Stone* it is all one, as if it were not mov'd at all, seeing that the *Air* and all the *Bodies* contain'd in it, are prest down by the *subtil matter*, and are whirl'd about together with the *Terrestrial Globe*. This is proved by a *Stone* falling from the *Mast* of a *Ship*, which whether it move, or stand still, the *Stone* ever falls down in the same place. The reason whereof is plainly this, because the *Stones motion downwards*, which it derives from the *Celestial matter*, is accompanied with a *Lateral motion*, communicated to it by the *Ship*, which is swiftly driven along. And consequently it is not strange at all, that it falls down *perpendicularly*, because the *Stone* moves as much forwards as the *Earth*, and consequently one and the same point of the *Earth* ever answers to the *Stone*, and therefore upon it the *Stone* must needs fall.

VII.
The motion
of a Stone
falling
down is not
straight,
but accord-
ing to a
Paraboli-
cal Line.

Tho' indeed to speak exactly concerning these things, we must own, that *heavy Bodies* do not fall downwards by a *Right*, or *Perpendicular Line* to the surface of the *Earth*, but by a kind of *Transverse* or *Crooked*, called a *Paraboli- cal Line*: and the Reason why the motion of a *Stone* appears to be *Right* and *Perpendicular*, is, because the *Eye* doth not perceive that motion whereby it self is moved, and which is common to it with the *Stone*, but only that motion which proceeds from the *Action* of *Gravitation*, or which is imprest upon the *Stone*, by him that casts it.

VIII.
A Third
Objection
from the
Shot of a
Gun.

Against this Solution it may be, will be urged an *Argument* taken from the *Shot* discharged out of *Great Guns*, viz. how it comes to pass, the *Earth* being moved about its own *Center*, that a *Bullet* discharged from the *East*, should not move more slowly than another that is discharged from a like *Gun*, and an equal quantity of *Powder* from the *West*? For if the *Earth* be carried from *West* to *East*, it must necessarily follow that the *Bullet* discharged from the *West*, must much exceed the swiftness of the other, as being assisted and promoted by the *Circumvolution* of the *Earth* the same

way; whereas the other is as much obstructed by the same, because it moves a quite contrary way.

I Answer in the *First Place*, that when a *Bullet* is discharged towards the *West*, as much as the *Earth* moves towards the *East*, so much is the *Bullet* also driven back that way, by the common motion of the *Vortex*: and on the contrary, when a *Bullet* is discharged towards the *East*, as much as the *Earth* has the same way, so much is the *Bullet* retarded by the *Vortex* of the *Earth*.

I Answer in the *Second Place*, that the motion of the *Earth* which is common to it with the *Air*, and other *Bodies* contained in it, doth neither hinder nor promote the motions of particular *Bodies*; and consequently, that all things happen in the same manner, as if the motion of the *Earth* were not determined to any certain part. As is manifest from this *Example*. Suppose we, a *Boat* to be driven with great swiftness to some particular *Region*, and one part thereof to be full of *Water*, in which two *Fishes* are swimming, the one from the *East* to the *West*, and the other from *West* to *East*; no body will imagine, that that *Fish* whose motion conspires with that of the *Boat*, will therefore move faster than the other. For it is certain, that which way soever they move, it will be with equal swiftness, as if the *Boat* were not moved at all. Thus the motion of the *Earth* from *West* to *East*, is no hinderance at all to those *Bodies* that move the contrary way. Yea the motion being common, its the very same, as if there were none at all.

For as these *Fishes*, besides the motion they have from their *Animal Spirits*, whereby they are carried which way they please, have also a motion imprest upon them from the *Boat*: In like manner a *Bullet*, besides that motion communicated to it by the *Gunpowder*, which carries it straight forward, hath another motion imprest upon it by the *Earth*, whereby it is whirl'd about in the same swiftness with it from *West* to *East*, and therefore runs through the same spaces as if there were no motion at all in the *Earth*.

Others again raise this *Objection* against the motion of the *Earth*: Supposing the *circumvolution* of the *Earth*, say they, there would always be a sensible Breez of *Wind* upon the *Surface* of it, as we perceive when we ride on *Horseback*, we are sensible of a kind of a Breez of *Wind* coming against our *Faces*, because the motion of the *Horse* exceeds the motion that is in the *Air*. Accordingly what a strong Breez of *Wind* ought we to feel, if with so swift a whirling about, as that of the *Earth* is supposed to be, we should run against the opposing *Air*? Wherefore seeing we find nothing of this, we have reason to conclude, that there is no such motion at all.

But this *Objection* is not so much the effect of *Reason*, as of an inveterate Prejudice about the stability of the *Earth*, which makes it a difficult thing for some men to conceive, that the *Air*, with all other ambient *Bodies* to the *Moon*, are carried about together with the *Earth*. Whereas, to speak exactly, the *Heavenly matter* that carries the *Earth* along with it, is more swiftly moved about the *Earth* than the *Earth* it self is about its *Axis*. Wherefore, in this Case, no wonder if we feel no *Wind* at all, no more than it is strange that a man

IX.

together
with the
Earth, it
cannot seem
strange
that we
feel no wind
from the
motion of
the Earth.

that pursues us with a *Sword* doth never reach us, in case we move faster than he.

XIV.
A Fifth
Objection
from Holy
Scripture.

The Authorities taken from *Scripture* seem to be of more force against this Opinion: For the *Scripture* in many places attributes stability to the *Earth*, and to the *Sun* a motion from East to West, as in the 1st Chapter of *Ecclesiastes*, where it is said, *The Sun ariseth, and goeth down, and hasteth to his place where he arose.* And in the Book of *Joshua* it is reported for a *Miracle*, that the *Sun* stood still at the Prayer of *Joshua*, when he said, Chap. 10. 12. *Sun, stand thou still upon Gibeon.* Now this would not have been a *Prodigy*, if the *Sun* had always stood still in the midst of the *World*, and the *Earth* had whirl'd about it; for if so, it had been more proper for *Joshua* to have said, *Earth, be not thou moved.*

XV.
The Scri-
pture in
many places
accommo-
dates it self
to our man-
ner of con-
ceiving of
things.

To which I Answer, That it is generally owned, that the *Scripture* speaks of things according to the manner of men, that is, our way of conceiving them. As when the *Scripture* speaks of the *Ends* and *Foundations* of the *Earth*, neither of which do properly belong to it. In like manner, when it attributes to the *Sea*, an *Abyss* of an unmeasurable depth, with other various *Affections* and *Motions*, which it hath not. Thus likewise it is said in the 1st Chapter of *Genesis*, that *God made two Great Lights, the Greater to rule the Day, and the Lesser to rule the Night.* Which can only be understood as to outward appearance, and not according to exact *Truth*. Because the *Sun* and *Moon* are not the greatest *Lights*, especially not the *Moon*, for *Saturn* and any of the *Fixt Stars* are greater than it. Neither can the *Moon* be called absolutely the least *Light*, seeing that *Mercury* is much less. And therefore we must conclude, that the *Scripture* calls them so, only because they appear so to us, and are accounted so according to vulgar opinion. And upon the same account it is, that the *Earth* in *Scripture* is said to stand still, and the *Heaven* to move about it; because, as to our sight, the *Earth* seems rather to stand still, and the *Sun* to be whirl'd about it, than the contrary. The same thing happening to us in this case, as to those that *Sail*, to whom the *Shoars* seem to withdraw, tho' indeed they withdraw or depart from the *Shoar*. When therefore *Joshua* said, *Sun, stand thou still*, this is not to be understood, as if the *Sun* then had been stop'd in his motion, and made to stand still; but only that the *Light* of the *Sun*, at *Joshua's* Prayer, continued without change, by which means the *Body* of the *Sun* seem'd to stand.

XVI.
The Obje-
ction far-
ther urged
from Scri-
pture.

If it be urged, that this Explication cannot be admitted, forasmuch as in many other places of Holy *Scripture* the stability of the *Earth* is plainly asserted: As in the 92 d. Psalm, *The Earth is established, that it cannot be moved*, and the 1st. of *Ecclesiastes*, *One Generation passeth away, and another cometh, but the Earth standeth for ever.* For how can the *Earth* be said to stand fast for ever, when indeed it is continually in motion?

XVII.
The Obje-
ction an-
swered.

I Answer, that these places are not so to be understood, as if the *Earth* were immoveable, and did not turn about its own *Axis*, but only that there is such a firm and indissoluble union of its parts, that it continues the same, notwithstanding the perpetual generation and corruption of *Animals*, *Plants*, and other things that are upon

it. So as that passage of the *Poet* may be attributed to the *Earth*.

*The same that our Progenitors did see,
The same is now, and still shall be.*

And that this is the genuine sense of this place, plainly appears from the foregoing words, *one Generation passeth away, and another cometh.* As if it had been said; tho' the *Earth*, according to some of his parts, be changed by means of *Generation* and *Corruption*, yet it standeth for ever, that is, it always continues in the same state: Much after the same manner as a *Ship* is said to continue the same, though it hath been often repaired, and several new *Parts* put instead of the old and decayed.

CHAP. V.

Concerning Day and Night, and the Vicissitudes of Seasons.

A Day is commonly taken by *Philosophers* for the stay of the *Sun* above the *Horizon*: In which sense it is opposed to *Night*, which is the abode of the *Sun* under the *Horizon*. Or else a Day is taken for that Duration in which the *Sun* is conceived to run round the whole *Earth*. The *Astronomers* call the former of these an *Artificial*, and the later a *Natural Day*, as containing both the *Artificial Day* and *Night*.

A *Natural Day*, is either *Astronomical* or *Civil*. An *Astronomical Day* is that space of time, wherein the whole Revolution of the *Aequator* is absolved, together with that portion of the *Aequator*, which answers to that part of the *Ecliptick*, which the *Sun* in the same time is understood to run through. The *Civil Day*, is that which is determined as to its Beginning and Ending, according to the custom of particular *Cities* or *Nations*. Thus the *Italians* begin their Day from *Sun* set; the *Babylonians* from the Rising of the *Sun*; the *Umbrians* from *Noon*; the *Romans* from *Midnight*, &c.

A Year, which consists of Days and Nights, is that time, wherein the *Sun* runs through the whole *Ecliptick*, or all the Signs of the *Zodiack*; which it doth in 365 days, 5 hours and 49 minutes; Which form of the Year, that it might be observed throughout the whole *Roman Empire*, *Julius Caesar* appointed that the 5 hours, with the 49 minutes, which the Year contained over and above the 365 days, should every fourth Year make one Day, which should then consist of 366 Days.

But forasmuch as these 20 hours with their minutes could not make up a whole Day, it was so ordered that those minutes which were added to every Year, over and above the due length of it, by process of time were so increased, as by exact computation to amount to 10 days. And consequently also the *Vernal Equinox* had changed its place, so as that the *Sun*, which entred *Aries* at the beginning of *Christianity*, on the 21st day of *March*, did about 1500 years after, enter the same about the 11th day. To remedy which error, *Pope Gregory XIII.* restored the *Equinox* to its former Seat, and by taking away 10 days, made it to return to the 21st of *March* again. Which is the Reason

I.
What a
Natural
and Arti-
ficial Day
is.

II.
A Natural
Day is ei-
ther Astro-
nomical or
Civil.

III.
What a
Year is.

IV.
Why a Year
is not the
same every
where, and
why the
English dif-
fer in their
computati-
on from
some other
Nations.

Reason why we here in England, not receiving this Reformation of the Kalender, differ 10 days from the account of others; so that when in France it is the 1st. day of March, it is no more than the 11th. day with us, and so on.

V. Forasmuch as the Diversity of the Days, Nights and Seasons of the Year, are consequent upon the motion of the Earth; we are to take notice of a threefold motion in the Earth, viz. A Diurnal, Annual, and Motion of Inclinations.

VI. The Diurnal motion, is that whereby the Earth is whirl'd about from West to East, in the space of 24 hours. This motion, according to our Hypothesis, doth not properly belong to the Earth, but to the fluid matter, in the midst whereof the Earth being poised, is together with the Atmosphere, carried about, not by a motion of its own, but of the Fluid Heaven that surrounds it: so that according to DES CARTES his Opinion, motion doth not properly belong to the Earth, but to the little Vortex which carries the Earth round with it self.

VII. The Annual motion, is that whereby the Earth runs through the Ecliptick in a years time; which motion is also imparted to it by the Fluid matter, whereby it is pois'd, which being whirl'd round by the force of the Solar matter, doth necessarily carry about with it all the Bodies that Swim, or are poised in it. The Earth therefore being carried about the Sun, between the Orbs of Venus and Mars, runs through the 12 Signs of the Zodiac in a years time. Now how the Earth can, besides its turning round, about its own Axis, perform a circuit about the Sun, we may learn by the Example of a Top, which turning round upon your Hand, may by you in the mean time be carried round a Tree, without hindring the motion of it about its own Center.

VIII. The motion of Inclination or Declination of the Earth, is the Deflexion of its Axis, from a Parallelism with the Axis of the Ecliptick, and ever keeping it so in every Situation, that it may always continue Parallel to the Axis of the World. So that indeed this motion, is not so much a distinct motion from the foregoing motions, as a certain modification of them; for whilst the Earth absolves its Diurnal and Annual motion, it always hath its Poles directed to the same parts of Heaven.

IX. These three motions of the Earth will be apprehended without difficulty, by comparing the two former to a Bowl delivered out of ones Hand, and rowling along the ground: and the third to a Flag fixt to the Mast of a Ship, but so, as to be able to turn round, in which Flag we suppose the Globe of the Earth to be painted, with its Axis, not placed right upwards, but somewhat leaning on one side, parallel with the Axis of the Terrestrial Globe. Now suppose a Ship, in which a Mast and Flag is, were to sail round some Castle or Fort, a strong South Wind blowing, it is manifest that this moveable Flag on the top of the Mast, would not turn about with the Ship, but by the force of the Wind, would be always directed towards the North, together with the Axis painted in it. So that by that time the Ship, pursuing its course, had performed one round, about the Fort, the Flag also would have perform'd one round, about the Iron Pin to which its fastned,

contrary to the motion of the Ship; the Axis of the painted Globe of the Earth being still directed towards the same part of Heaven.

The Orb, whose middle Line the Earth, by its Annual motion describes, is called the Great Orb, which with regard to the fix'd Stars is but like a Point, according to our Hypothesis, so great is the distance between the fix'd Stars and the Earth; and therefore 'tis all one, whether the Stars be viewed from the Center of this Great Orb, or from the Circumference. And thus much will be readily admitted by those who consider how rash a thing it is, to define the Works of GOD to be less August and Ample, than indeed they are; and especially if we consider, that the Appearances can no other way be explained; neither doth Reason oppose it, seeing that the whole Earth is but a Point, compar'd with the Sun: Which is prov'd by this Instance, because the Sun seems to move about a Round Sun-Dial placed upon the Surface of the Earth, after the same manner as it Rolls about the Earth; which shews, that the Diameter of the Earth is of no account in this case.

It is to be noted also, that the Axis about which the Earth, in a Days time, turns round, is not perpendicularly raised above the Plain of the Ecliptick, in the which, in a years time, it is whirl'd about the Sun; but declines above 23 Degrees from a Perpendicular. The reason whereof is, because the striate Matter of the first Element, which enters into the Poles of the Earth, near to the Poles of its Axis, coming from that part of the Vortexes which constitute the second Heaven, doth in this manner inflect or turn it aside: The other Parts of the Earth having not their Pores so dispos'd, that other subtil Matter, coming from other parts of Heaven, should enter into them, and turn it another way.

The Necessity of the Motion of the Axis of the Earth appears from hence, that without it there would be no inequality of Days and Nights, but the Inhabitants of the same place would always have the same length of Days and Nights, and the same constitution of the four Seasons of the Year; that is, some would have all the year, Winter, others Summer, others Autumn, and others Spring. Wherefore it is of absolute necessity to admit the motion of Inclination, to salve the Appearances, and to make all things agree in Harmony.

Forasmuch therefore as the Earth is a great Spherical Body, and at a great distance from the Sun, its whole extension cannot be enlightened at once, but only one half of it; and therefore when the Earth is once carried about its Axis A B in the space of 24 Hours, it makes the same part of the Earth, when turn'd toward the Sun, to enjoy Day-light; and when turn'd away from him, to have Night. For Day is said to be in that Part of the Earth, which being turn'd to the Sun, receives its Rays; and Night in that Part, which being turn'd from the Sun, cannot immediately receive them. And therefore it is no wonder, if the Parts of Heaven seem to arise and go down; because by the Revolution of the Earth they are gradually discovered, and seem in order to approach towards us; and on the opposite side to set and vanish.

And

X. The Great Orb, is but a Point in comparison with the fix'd Stars.

XI. The Pole of the Earth declines 23 Degrees from the Pole of the Ecliptick.

XII. Without the Motion of Inclination, there could be no difference of Seasons.

XIII. How Days and Nights come to be

Figure 39.

XIV.
Whence
the diver-
sity of Sea-
sons of the
Year aris-
eth.

And because the *Axis* of the *Earth* A B, (as hath been said already) about which its *Diurnal Revolution* is performed, doth at present decline almost 23 Degrees from the Perpendicular I, 6 of the *Ecliptick*, in which the *Earth* in a *Years* time performs his *Course* round the *Sun*; it so is, that the *Earth*, in various parts of its *Orb*, by objecting these two *Poles* of the inclined *Axis*, more or less, turned to or from the *Sun*, and exposing its several parts, sometimes for a longer, at other times for a shorter Space to the *Sun*, doth by this means produce the different *Seasons* of the *Year*, and the *Inequality* of *Days* and *Nights*. So that that part of the *Earth* which hath its *Axis* more inclin'd towards the *Sun*, enjoys *Summer*, as admitting the more direct *Rays* of the *Sun*, and consequently stronger and hotter: Whereas in that part which hath its *Axis* more turn'd away from the *Sun*, it is *Winter*, because it receives the *Rays* of the *Sun* more obliquely, and consequently more scatter'd and less agitated. And that part which continues longer turn'd toward the *Sun*, enjoys longer *Days*; as that which is for a less time illustrated by the *Sun*, has shorter *Days*.

XV.
There are
four Signs,
to which
when the
Earth ap-
proacheth,
she produ-
ceth the
different
Seasons of
the Year.

This will appear more manifest, by shewing how the *Seasons* come to be, and how it happens that with some *Inhabitants* of the *Earth* it is *Spring*, with others *Summer*, with others *Autumn*, and with others *Winter*. Let us place therefore 4 Points, *Libra* ♎, *Capricorn* ♐, *Aries* ♈, and *Cancer* ♋, as Centers, or 4 Equal Circles, that may represent the *Earth* to us, placed there at divers *Seasons*; the *Earth* with its Center running through the whole Circumference of *Libra*, *Capricorn*, *Aries* and *Cancer* in a years time, from *West* to *East*, according to the Order of the Signs.

XVI.
How Spring
comes to be.

For it is manifest, that the *Earth* being placed in the Point of *Libra* ♎, at the same time that the *Sun* is in the opposit Sign of ♎, *Spring* time begins with us, who inhabitate the North parts of the *Earth*; because the North Pole of the *Earth* A, being constituted between its past greatest Declination from the *Sun*, and its future greatest Inclination to it, makes, that the *Sun-beams* falling upon our *Temperate Zone* 1, 2, reach it only obliquely; and therefore make the *Air*, yet thick and sluggish by reason of the *Winters Cold*, more temperate about this time of the *Year*. And forasmuch as both the *Poles* A B, about which the *Earth* is carried by its *Annual Revolution*, are constituted in the Extream parts of the Hemisphere of the *Earth*, that is illuminated by the *Sun*; by this means it comes to pass that we, and all other *Inhabitants* of the *Earth* have equal *Days* and *Night*.

XVII.
How we
come to
have Sum-
mer, and
those who
live in the
South parts
Winter at
the same
time.

But when the *Earth*, in its *Annual Revolution*, comes nearer to *Capricorn* ♐, the North Pole A, doth further enter into the Hemisphere, illuminated by the *Sun*; whereas the Southern Pole B, is more withdrawn from it. By which means it comes to pass, that to those who live towards the North Pole A, the *Days* begin to increase, and the *Heat* to prevail; whereas those who live about the South Pole B, experience the contrary. But when the *Earth* is come quite to *Capricorn* ♐, viz. at the same time that the *Sun* appears in *Cancer* ♋, we enjoy *Summer*; because the North Pole A being at that time most inclined towards the *Sun*, it makes the *Sun-beams* to fall directly, and almost perpendicularly upon our *Temperate Region* 1, 2, and the

Cold Region 1, A; and therefore produceth the greatest *Heat*. But to them who live beyond the *Equator* 3, towards the South Pole B, *Winter* happens at the same time; because the *Antartick Pole* being at that time in his furthest declination from the *Sun*, the *Beams* thereof reach it very obliquely and consequently impart but very weak *Light* to them. At the same time the *Longest Days* are with us, and the *Heat* increaseth; because the North Pole A continuing for a long time in that Hemisphere of the *Earth* which is illustrated by the *Sun*, makes us to enjoy the *longest Days* and *shortest Nights*. The contrary to which happens to the Southern *Inhabitants*, because the *Antartick Pole* B, is then entred into the *Darkned Hemisphere*; and therefore makes, that those who inhabit the *temperate Zone* 4, 5, and the *Cold* 5 B, are for many *Hours* overwhelm'd with *Darkness*, and enjoy the *Light* but a very little Space.

Afterwards, when the *Earth* having left *Capricorn* proceeds to *Aries* ♈, the North Pole A, doth more and more decline from the *Sun*, towards the Hemisphere of the *Earth* that is cover'd with *Darkness*; but the *Antartick* B, towards the illuminated Hemisphere, which causeth the *Days* to be shortned to us, that live North; whereas those that live South, begin to have their *Days* and *Heat* increased: 'Till at last the *Earth* being arriv'd at *Aries* ♈, both the *Poles* being in the Extremes of both the Hemispheres, viz. of that which is enlightned, and that which is *Darkned*, produce Equal *Days* and *Nights* to all the *Inhabitants* of the *Earth*.

Last of all, As the *Earth* continues his Course from the Point of *Aries* ♈, towards *Cancer* ♋, the *Artick Pole* A by degrees begins to enter the *darkned Hemisphere*, and the *Antartick* or Southern Pole, the illuminated Hemisphere: By which means it comes to pass, that they who live beyond the *Equator* 3, begin to have longer *Days*; and they shorter, who live towards the North: Till the *Earth* being arriv'd at *Cancer* ♋, the North Pole becomes dipt 23 Degrees in the *darkned Hemisphere*, and thus makes *Winter* and the *shortest Day* to the Northern *Inhabitants*; whereas to those that dwell in the South, it makes *Summer* and the *longest Day*. Lastly, the *Earth* proceeds from the Point of *Cancer* ♋, to *Leo* ♌, and *Virgo* ♍; till that being arriv'd again at *Libra* ♎, it restores *Spring* to those of the North, and *Autumn* to those of the South.

All the foresaid *Seasons* of the *Year*, as to the length and shortness of the *Days* and *Nights*, in the continual process of *Years*, are much alike; because the *Diurnal* and *Annual Revolution* of the *Earth*, whence the Vicissitudes of *Days* and *Nights* do arise, are in all years much alike.

However, because the two Conversions of the *Earth*, viz. the *Annual* and *Diurnal*, would be more commodiously performed, if they were done about Parallel Axes, the Causes that hinder this are by degrees changed; whereby it comes to pass, that in process of time this declination of the *Ecliptick* from the *Equator* will grows less and less.

CHAP. VI.

Of the Zones and their Inhabitants, and of the Climats.

I. There are five Zones in the Earth; and what we are to understand by the word Zone.

II. The Torrid Zone.

III. The Temperate Zones.

IV. The Frigid Zones.

V. The Torrid Zone is not inhabitable, as was believ'd by the Ancients.

The Ancients, to distinguish the Degrees of Heat and Cold on the Surface of the Earth, did divide it into 5 Zones, viz. into the Torrid Zone, 2 Temperate, and 2 Cold Zones. By the Name Zone they understood a space of the Earth, lying between the two Tropicks; or one of the Tropicks, and the next Polar Circle; or between either of the Polar Circles, and the Neighbouring Pole. So that the Zones are nothing else, but different Regions of the Earth differing in Temperature, according to the Sun's Nearness, or Distance.

The Torrid Zone, is that Space which is comprehended between the Tropicks; the Northern part whereof reacheth 23 Degrees and an half from the Equator; and the other part, as far towards the South: So as that the whole Space contains 47 Degrees in Latitude; and is therefore called the Torrid Zone, because it is scorched by the perpendicular Beams of the Sun.

The Zones that are placed between the Tropicks and the Polar Circles, are called Temperate; the one of them being between the Tropick of Cancer and the Arctick Circle, which is 43 Degrees broad. And this is called the Temperate Zone towards the North. The other is call'd, the Temperate Zone towards the South, between the Tropick of Capricorn and the Antartick Circle, and hath as many Degrees in Latitude as the former.

The other two which are comprehended within the Polar Circles, are called Frigid or Cold: Whereof one is the Northern Frigid Zone, between the Arctick Circle and the North Pole; from which Circle to the Pole, are accounted 23 Degrees and an half. The Southern Frigid lies between the Antartick Circle and the South Pole, and is just as many Degrees in Latitude.

The Ancients believ'd the Torrid Zone to be Inhabitable; according to that of Ovid,

—of these, the Middle Zone,

Is scorch'd with Heat, inhabited by none.

But Experience hath now better inform'd us; for the Spaniards, Portuguese, Hollanders, and also the English, who have Sailed round the World, as they call it, have found the Torrid Zone not to be scorch'd with intolerable Heat, but Temperate enough, and water'd with plentiful Showers, and with frequent Rivers and Springs, abounding also with all manner of Fruit and Corn, and affording a pleasant and delightful Abode to Animals and Men, so as that People of several Nations come to inhabit there. This appears also consonant to Reason; because the Length of the Nights, which are equal to the Days, in those Regions, doth greatly allay the heat of the Air. Neither are there wanting in this Space many Lakes, Pools, and other moist places, whence copious Vapours are raised, which afterwards coming down in Rain, do allay and temper the heat of the Sun. For tho' the Rains that fall there be but small, yet they are so frequent, as sometimes to continue for some Months together, greatly favouring the growth of Plants, and conducing to the refresh-

ment of Men, and other Living Creatures. Which inclines me to be of Polybins his Opinion, who asserts that part of the Earth under the Equator to be more Temperate, than that which is under the Tropicks; because when the Sun is about the Equator, he presently runs over the Vertical Point; but when at the Tropicks, he continues Vertical for several Days.

There is a difference amongst the Inhabitants of the Torrid Zone: For some of them live under the Equator, others under the Tropicks, and others again between the Equator and the Tropicks. The Sun toucheth the Zenith or Vertical Point of all these, once or twice every Year. They who live under the Equator, in the first place, have a Right Sphere: Secondly, They alone enjoy a Perpetual Equinox: Thirdly, They alone have the view of both Poles: Fourthly, To them alone all the fix'd Stars Rise and Set: Fifthly, They have two Summers and two Winters: Sixthly, The Sun passeth their Zenith twice in a Year. Those who live under the Tropicks do first experience two Meridional Shadows, in a Years time: Secondly, They have but one Summer, and one Winter: And lastly, The Sun reacheth their Zenith once in a Year. They who live betwixt the Equator and the Tropicks, have 3 South shadows in a Year; in the next place they have 2 Summers and 2 Winters, especially if they be more remote from the Tropicks: Thirdly, The Sun passeth their Zenith twice in a Year.

The Inhabitants of the Temperate Zones, in the first place, have one South shadow in a whole year: Secondly, They have two Solstices: Thirdly, They have one Summer and one Winter in a year: Fourthly, The Sun never reacheth their Vertical Point: Fifthly, They have 2 Equinoxes every year, as all those have that have an oblique Sphere, or that dwell betwixt the Equator and the Poles.

The Inhabitants of the Frigid or Cold Zones, are of 3 sorts: For they either live under the Polar Circles, or under the Poles themselves; or betwixt the Circles and the Poles. They who live under the Polar Circles, do alone enjoy a Day of 24 Hours long; and all other things which happen to the Inhabitants of the Temperate Zones, happen also to them. They who live under the Poles, have a Day of 6 Months, to which succeeds a Night of the same length. They have never any Equinox, and to them alone no fix'd Stars ever Rise or Set. But they who live betwixt the Poles and the Polar Circles, their longest Day in the Summer is above 24 Hours. They do not see the Sun, whilst he is in the Tropick of Capricorn. Other things they have common with those that live under the Polar Circles.

Another Distinction of the Inhabitants of the Earth is taken from the opposite situation of their Habitation; and this Difference is Threefold, being distinguish'd into Beriæci, Antæci, and Antipodes.

They are call'd Beriæci, who live under the same Parallel, and the same Meridian, but yet under the opposite Points thereof. Such are those who live in the places marked 7 and 8, and 3 and 6. Now all these have the same Summer and Winter, and much the same Temperature of the Air, and the same Length and Shortness of Days

VI. The Inhabitants of the Torrid Zone, are in a threefold difference.

VII. The Inhabitants of the Temperate Zones.

VIII. The Inhabitants of the Frigid Zones.

IX. The difference of the Inhabitants of the Earth, with respect to their situation.

X. Beriæci.

Fig. 40. and

and Nights; but have their Day and Night at a contrary time to one another: Except they be placed within the *Frigid Zone*, because then it may so happen, that they have the same Day and Night.

XI.
Antæci.

Antæci are those that live under *Parallels*, that are equally distant from the *Equator*, and under the same *Meridian*, in the same *Longitude*. Such are those who dwell in the *Points* 3 and 7, and in 6 and 8. They have the same *Noon* and *Midnight*; but have their *Summer* and *Winter* at opposite times: So as that the longest Day of one of them, is the shortest Day of the other. The *Antæci* between the *Tropicks* may have the same *Winter*, but never *Summer* at the same time.

XII.
Antipodes.

Antipodes, or *Antichthonæ*, are those who live under *Parallels* or *Points* distant the same *Latitude* on either side of the *Equator*; or under the *Equator* it self, but yet in opposite *Points* of the same *Meridian*: Or more briefly, as *Cicero* has it, *Antipodes* are those whose steps are opposite to each other. And such are they who live in 1 and 2, 5 and 4, 6 and 7. The *Antipodes* without the *Equator*, 5 and 4, have all things opposite. Those at 5 and 4, have *Night* and *Day* quite contrary: And all the rest have also their *Summer* and *Winter* at contrary times. There is no *Point* assignable on the *Surface* of the *Earth*, to which an *Antipodal Point* doth not answer; and this is nothing else, but the other *Extremity* of the *Diameter* from the foresaid *Point*, passing through the *Center* of the *Earth*. Whence it is, that these great *Varieties* must needs happen.

XIII.
The Opinion
of the An-
cient con-
cerning the
Antipodes.

Those who are our *Antipodes*, live towards the *South Pole*, and are yet undiscover'd what kind of *People* they are; but the *Antipodes* of other *Nations* are known. For though some Great Men of Old did deny *Antipodes*, as supposing that if any such were, they must hang in the *Air*, and have their *Heels* higher than their *Heads*; yet these are worthily derided by *Lactantius*, *Lib. 4. cap. 14. de Falsa Sapiencia*; forasmuch as the *Inhabitants* of the *Earth*, in what part soever they live, tread upon the *Earth* with their *Feet*, which every one may easily understand that considers the *Earth* to be *Round*.

XIV.
Why the
Surface of
the Earth
was divi-
ded into
Climats.

But because the *Distinction* of *Zones* did not seem sufficient to the *Ancients*, to specify all the diversity of the *Situations* of *Regions* about the *Equator*, they thought convenient to add many *Parallels*, by which, as by so many lesser *Zones* they divided the *Earth*, and called them *Climats*, as being so many *Inclinations* or *Deflexions* from a *Right Sphere*. Yet there is this difference betwixt the *Parallels* and *Climats*; that the *Parallels* are only of one *Quarter* of an *Hour*, but the *Climats* of Half an *Hour*. So that in whatsoever place of the *Earth* the *Solstitial Day* is one *Quarter* of an *Hour* longer than 12 *Hours*, that place is under the first *Parallel*. But if the *Excess* reach to Half an *hour*, that place is situate under the second *Parallel*; or, which is the same, under the first *Climat*. For by *Climats* the *Ancients* understood nothing else, but large *Spaces* of the *Earth*, or *Zones*, between two *Circles Parallel* to the *Equator*, equal in *Latitude*, and passing through every 10th *Degree* of the *Meridian*. These are 18 in all, 9 whereof are called *Northern*, and 9 *Southern*.

The first *Climat*, from the *Equator* towards the North, hath its beginning where the Longest Day is of 12 *Hours*, and its *Latitude* or distance from the *Equator* is 10 *Degrees*; towards the further part of which, the Longest Day is 12 *Hours*, 35 *Minutes*. It is commonly called *Ethiopicum*, from the Country of *Ethiopia*, as passing over the City *Meroe*. For the Custom of the *Ancients* was, to put the Name of some Famous place contained in it upon the several *Climats*.

The second *Climat* is that, where the *Latitude* is of 20 *Degrees*, and the Longest day of 13 *hours* and 12 *minutes*, and is called *Arabicum*, from *Arabia Felix*, through which it passeth.

The third is that where the *Latitude* is of 30 *Degrees*, and the Longest day of 13 *hours* and 56 *minutes*: And took the Name *Egyptiacum* from *Alexandria*, the Metropolis of *Egypt*, through which it passeth.

The fourth *Climat* is that, where the *Latitude* is of 40 *Degrees*, and the Longest day of 14 *hours* and 51 *minutes*. It is called *Syriacum*, because it passeth through *Rhodes* in *Syria*.

The fifth is, where the *Latitude* is of 50 *Degrees*, and the Longest day of 16 *hours* and 9 *minutes*; and it was call'd *Italicum*, or *Gallicum*; because it passeth through *Rome* and *Paris*, where the Longest day is of 16 *Hours*.

The sixth is where the *Latitude* is of 60 *Degrees*, and the Longest day of 18 *hours* and 30 *minutes*; and this is called *Britannicum*, or *Germanicum*.

The seventh is, where the *Latitude* is of 70 *Degrees*, and the Longest day of 65 *Days*; and is commonly call'd *Suecicum*.

The eighth is, where the *Latitude* is of 80 *Degrees*, and the Longest day of an 134 *Days*; and is called *Glaciale Boreum*.

Lastly, The ninth is that *Space* which is extended to the *Northern Pole*, where the Longest day is of Half a year, or of 188 *Days*, and is called *Polare Boreum*.

The first of the *Southern Climats* begins at the *Equator*, and ends in the 10th *Degree*, where the Longest day is of 12 *hours*, 35 *minutes*. It takes its name of *Brasilianum*, from the Country of *Brazile*.

The second is, where the *Latitude* is of 20 *Degrees*, and the Longest day of 13 *hours* and 12 *minutes*: And is called *Peruanum*, from the Country of *Peru*.

The third is, where the *Latitude* is of 30 *Degrees*, and the Longest day of 13 *hours* and 56 *minutes*; and is called *Paraguaticum*.

The fourth is called *Chiliacum*, from the Country of *Chili*, which is extended 40 *Degrees* towards the South; where the Longest day is of 14 *hours* and 51 *minutes*.

The fifth is, where the *Latitude* extends to 50 *Degrees*, and the Longest day is of 16 *hours* 9 *minutes*. It is called *Sylvestre*, because it is inhabited by *Savages* and *Wild People*.

The sixth is call'd *Magellanicum*, where the Longest day is of 18 *hours* and 30 *minutes*, and reacheth to 60 *Degrees*.

The seventh is of 70 *Degrees*, and is call'd *Incognitum, Unknown*; where the Longest day is of 65 *Days*.

XXXII. The ninth and last is extended to 90 Degrees, where the Longest day is of 6 Months, and is called *Polare Austrinum*.

XXXIII. Formerly there were only 7 Climes, because they contained all the Countries that were then known: But the Earth being more known and discover'd, is now distinguish'd into 18 Climates, which Astronomers call by another name, Elevations of the Pole; and Geographers, the Latitudes of Places, or their Distances from the Equator.

CHAP. VII.

Of those things which are generated in the Earth; and first of Fountains.

I. **F**ORASMUCH as Fountains break forth on the Surface of the Earth, and proceed from its bowels, we must enquire in the first place, what is the Original of Fountains, and from what Principle they are derived. And this we find can be nothing else but the Sea: For seeing that many Fountains flow continually, and that the Rivers which are made by them, do without ceasing continue their Course towards the Sea, without ever increasing the same, according to that of the Wise King in the 1st of Ecclesiastes: *All the Rivers run into the Sea, yet the Sea is not full; unto the place from whence the Rivers come, thither they return to flow again.* And accordingly we may easily gather, that the Original of Fountains is from this, That the Sea-Water being driven into the Bowels of the Earth, is led up to the Surface thereof; where breaking forth, it at last, after various Turnings and windings, returns to the Sea.

II. And indeed, forasmuch as the Earth contains many Clefts, by which, as by so many Channels, the Water may be carried from one place to another; there is no reason to oppose, but that Water may come from the Sea, to the bottoms of Mountains; and that the same which break forth in Springs from those Mountains, may after various windings run again into the Sea. Much after the same manner, as we find that in Living Creatures the Blood is carried from the Left Ventricle of the Heart, through the Aorta into the Arteries and Veins, and after having finish'd its Circulation, returns to the Vena Cava, and from thence to the Heart, from whence it came forth at first.

III. But forasmuch as the Surface of the Earth is not even, some part of it being stretch'd out into Plains and Levels, and others rising into Mountains, which do far exceed in height the Surface of the Ocean; we are to enquire, by what means the Water becomes rais'd from the Depths of the Earth, to the Tops of the highest Mountains; as also how the Sea-Water becomes deprived of all its Saltiness, when it breaks forth into Springs and Fountains whose Waters are fresh.

IV. As to the first of these, some are of Opinion that this is performed by the Earth, to which they attribute a Virtue of sucking and attracting the Water to the tops of the Mountains: After the same manner as Bread being dip'd in Wine, doth

suck and draw up the Wine into it self; or as a Sponge, sucks-up Water. But this way of explaining this Difficulty is not Rational, since Sucking presupposeth a sensible Motion in the Body that sucks; for I cannot suck without some dilatation and swelling of my Body: Neither can it be suppos'd that the Earth can perform any such action. And as to the Instance of Bread, or a Sponge dip'd in Water, nothing can be infer'd thence to prove, that the Earth sucks up the Water to the tops of the Mountains; seeing that it is but a small quantity of Water that is suck'd-in by the Spongy Body; and that that which is attracted by it, doth never run out from it. And so likewise may that part of the Earth, which lies next to the Spring, be moistned and soak'd through with the Water of it; but this will never make the Water spring or break forth from thence.

Others suppose, that the Sea-Water is rais'd to the highest parts of the Earth, by means of that pressure whereby the surface and upper-part of the Sea-Water presseth that which is at the Bottom, and forceth it up the passages of the Earth, till having at last found an Out-let, it breaks forth on the Surface thereof. But neither can this Opinion be admitted; for tho' the Water at the bottom of the Sea, be driven into the Cavities and open Passages of the Earth, by the weight of the Water that lies upon it; yet can it not by this means be rais'd higher than the Surface of the Sea. Besides, if the Water by some Channels, or wide and open Passages, should be conveyed by one continued Channel, from the Sea to the Surface of the Earth, then it would not be fresh, but salt; because the Salt easily gets through those places, where the Water in any quantity can pass; and so all Springs would be as salt, as the Sea it self.

We suppose therefore, that the Water in those Holes and Caves, whither it is driven by its weight, is resolv'd into Vapours by the Subterranean heat; and that this Heat, by those Passages which it every where meets with, mounts it upwards, and raises it to the tops of the Mountains. To which may be added, that the Pores through which the Vapours tend upwards, are continued open towards the very tops of the Mountains, and that they more easily mount up through the said Pores, because they are supported by the Particles of Earth, than through the Air, whose fluid and soft particles, cannot so uphold them and assist their Elevation. Now that there are such Subterraneous Fires, that turn the Water into Vapours, is evident from those Fire-Vomiting-Mountains, *Hecla, Vesuvius, Aetna*, and others of the same nature. And tho' such Fires do not break forth from all parts of the Earth; yet it is probable that they communicate their Heat far and near, by means of hollow Passages in the Earth, in the same manner as the inborn Heat is dispersed through the Guts and other parts of the Body.

But when the Vapours are thus mounted up, and are come near the surface of the Earth, they then become condensed by meeting with the Cold parts of the Earth; and by this means being unable to mount higher, they cling together, and are turn'd to drops of Water: And since in this state they are not able to return back by the same Passages, or Pores, because of their Narrowness, they are carried downwards by their own weight; where

V.
Nor by the pressure of the Sea-Water.

VI.
The Sea-Water being turn'd into Vapours, mounts upwards.

VII.
Condensed Vapours furnish the Fountains with Water.

where many of them being united together make a *Subterraneous Rivulet*; and many of these *Rivulets* gather'd together make a greater, which breaking forth out of the *Earth*, constitutes a *Living Fountain* or *Spring*. An Example whereof we have in *Chymical Distillations*; where, by the means of *Fire*, many *Vapours* are driven up the *Alembick* from moist *Bodies*, which are condensed in the cool Head of the *Still*, and being united into *Drops*, run down the *Neb* thereof.

VIII.
What
Springs or
Fountains
are.

So that *Springs* are nothing else, but *Sea-Water*, which being by its own weight driven to the bottom of *Mountains*, is there changed into *Vapours* by the inward heat of the *Earth*, and again condensed into *VWater* by the Coldness of the *Air*, or that of the tops of *Mountains*; whence these run down, according to the declining of the *Passages* that convey them, to the open place they have made for themselves on the side, or at the foot of the *Mountains*.

IX.
Why some
Springs are
dried up in
Summer.

Some, it may be, will object: If it be true that *Springs* have their Rise from the *Sea*, whose *VWater* being resolv'd into *Vapours*, by means of heat are again changed into *VWater*; how comes it to pass that some *Springs* are altogether dried up in *Summer* time, and do quite vanish by extream heat, since it cannot be question'd, but at that time many *Vapours* mount up from *Subterraneous places*, and that likewise there is Cold enough about the surface of the *Earth* to condense them.

X.
Answer.

I Answer, That these *Springs* which are subject to dry up in *Summer*, do for the most part owe their Original to *Rain* and *Snow*, which running through the *Clefts* of *Rocks*, do afterwards insinuate themselves through the *Pores* of the *Earth*, and drop down into some hollow places, and being there resolv'd into *Vapours*, by the Heat lodg'd in the *Bowels* of the *Earth*, meet with some proper place, by the Coldness whereof they become condensed, and so discharge themselves through some open passages on the surface of the *Earth*. Hence it is, that after long continued *Rains* we see many *New Springs* arise, which afterwards by degrees vanish, except more *Showers* succeed and fill those hollow places of the *Earth* from whence they proceeded, and supply Matter for a new breaking forth of *VWater*.

XI.
Of the
various
kinds of
Fountains.

Whence we may distinguish *Fountains* into several kinds, according to their different ways of *Flowing*, *Failing*, or *Duration*; and so *Springs* or *Fountains*, are either *Temporal* or *Perpetual*: *Temporal*, are those that do not run continually: *Perpetual* are such as *Spring* without ceasing. Which are again divided into *clear* and *pure Fountains*, falling down by drops, or gushing out with a *stream*; or *mixed*, being such as are impregnated with *Salt*, *Sulphur*, *Bitumen*, or *Few Lime*, and the like.

XII.
How Wells
come to be
generated
in the
Bowels of
the Earth.

Wells are furnish'd with *VWater* much after the same manner as *Springs* are: For after that the *Vapours* of *VWater* have been raised to the surface of the *Earth*, they are by the Coldness thereof changed into *VWater*; which afterwards wandering under *Plains* and *Mountains*, without being able to mount up to the surface of the *Earth*, are there turn'd into *Wells*. Now the reason why *Wells* cannot mount up above the place of its first Rise, for being come up to that pitch, it is equally

pois'd, and so can rise no higher. Another Reason also may be, because *Wells*, for the most part borrow their *VWaters* from *Rivers*, *Lakes*, and *Pools*, not far off: Or if they receive their *VWaters* from the *Sea*, the said *VWaters* being drained through the *Earth*, run together into one and the same place.

Hence it is that *Springs* and *Wells*, tho' they proceed from the *Sea*, yet their *Waters* are fresh, whereas the *Sea-water* is salt. The Reason whereof is this, because the *Sea-water*, consisting of fresh and salt *Particles*, whereof the fresh only are turned into *Vapours*, and carried upwards, leaving the salt particles behind, it is plain that their *Water* must be fresh. For the salt *Particles*, being stiff and inflexible, can neither be changed into *Vapours*, nor pass through the winding and bending pores of the *Earth*. The *Water* therefore of *Wells* and *Fountains* is fresh, because the *Sea water* being drain'd through much *Sand* or *Earth*, is depriv'd of its stiff saline *Particles*, and so becomes fresh.

If any Man enquire how it comes to pass, since only fresh *Water* is drained through the *Earth*, that notwithstanding much *Salt* should be found in some *Wells*, at a great distance from the *Sea*.

I Answer, That this may happen, because the *Passages* of the *Earth* in some places are more wide and open, through which the *Sea-water* passing freely, may reach those *Wells*, without leaving its saline particles behind it: Or, because the surface of the *Sea* may lye level with the bottom of those *Wells*; or likewise, because where the ways are wide and open, the particles of *Salt* are carried upwards by the particles of *Fresh-water*. Of which this is a confirmation, because in some *Mountains* are found vast lumps of *Salt* grown together like great *Stones*: For the *Sea-water* being got up thither, whilst the particles of *Fresh-water* mount still higher, the *Salt* is left alone in those *Cavities* it meets with there, and fills them up.

Some *Fountains* are famous for their *ebbing* and *flowing*, like the *Sea*; yet not all in the same manner. For there is one at *Cadiz*, and another at *Bordeaux*, that imitate the motion of the *Sea*, and *ebb* and *flow* at the same time with it. There is another in *Spain* which ebbs when it is flood at *Sea*, and flows when there is an *Ebb-tide* at *Sea*.

The Cause of this *ebbing* and *flowing* in *Fountains* cannot be attributed to any thing, but to the *Sea-tide*; by means whereof the *Sea* entering into some *Subterranean passages*, drives up the *Water* as high as it self riseth. But the Reason why these *Springs* variously imitate the *Sea-tide*, is to be deduc'd from the difference of the passages through which the *Water* is convey'd: For if these *Channels* be strait without windings, or if the distance from the *Sea* be small, the *Fountain* flows at the same time with the *Sea*, and falls again when the *Sea* ebbs. But if the *Water* be convey'd to the *Cavities* of *Fountains*, through many crooked and winding passages, it may so happen that the *Fountain* may not swell when the *Sea* flows, nor fall when it ebbs; but quite contrary may swell when it ebbs, and sink when the *Sea* flows; because the *Water* having so many winding passages to go through, much time is thereby lost, so that by that time the *water* of the *Fountains* begins to swell, the *Sea* begins to *ebb*.

C H A P. VIII.

Of Metals and Minerals.

I.
What Me-
tals are.

Metals are Bodies dug out of the Earth; Heavy, Hard, and Fusible by Fire, hid in the Inward part of the Earth, and there generated by the heat of the Sun, and subterraneous Fires. Such as are Gold, Silver, Copper, Iron, Tin, and Lead.

II.
Of what
Parts the
Metals are
compound-
ed.

The Particles which compose Metals, are Salt, Oil, and Earth; which being mingled together, and meeting in the long and branch-like Pores of the inward parts of the Earth, are in the same so straitly link'd together, that Art hath not as yet found out any means whereby to separate them.

III.
Which be
the pure
Metals.

Some of these are called *Pure Metals*, others *Impure*: *Pure Metals* are those, which compar'd with others, have been excoll'd or digested to a greater degree of fineness and perfection, by means of the Solar and subterraneous Heat; such as are Gold and Silver. Gold is the most heavy and most perfect of all Metals, very ductil, consisting of parts of equal Fineness and Heaviness, and being more heavy than the particles of Fire, cannot be carried away by them: Which is the Reason why Gold, when it is melted, loseth nothing of its weight, as having no Dross, which by the Action of the Fire might be separated from it. Silver is a Metal in Fineness and Perfection inferiour to Gold, heavy and solid, less ductil than Gold, and which being melted in the Fire, loseth something of its weight; more especially that which by the agitation of the Fire is turned to Dross.

IV.
Which the
Impure.

Impure Metals, are those whose Principles are not so mature and refin'd, nor so fix'd and pure. Some of these, because of their impure Earthy substance, are made Red-hot before they can be melted; as Copper and Iron: Whereas others of them, because of their abounding Moisture, are melted before they become Red-hot; as Tin and Lead.

V.
The Prin-
ciples of
the Chy-
mists exa-
mined.

To the end that the Nature, not only of Metals, but of Minerals also, may be the more clearly and distinctly known, it will be fitting that we know before-hand, what we are to understand by the Active Principles of the Chymists; and what the Philosophers mean by Salt, Sulphur, and Mercury.

VI.
What we
are to
understand
by the
word Salt.

By the Name of **SALT**, we understand a sharp Juice, consisting of slender and stiff particles, which being intercepted in the Pores of the inward part of the Earth, are beaten or forged into little Swords: For as a round Rod of Red-hot Iron, is by the frequent strokes of Hammers beaten into a longish thin Plate; so those particles, by being dash'd and rubbing against the hard Sides of the Pores of the Earth, are form'd into such Figures. Wherefore Salt is nothing else, but a sharp Juice, consisting of slender, stiff and sharp Particles. Which, if it be volatyl and very bitter, is called *Salt Armoniack*; if it be more fat and inflammable, growing to Walls and Rocks, 'tis called *Nitre* and *Saltpeter*; if it be found in Mines and Mineral-waters, *Allom*; if it be joyn'd with a Metallick matter, and a most sharp and subtil Mercurial Juice, 'tis called *Vitriol*.

By **SULPHUR** we understand, the very soft and minute Branchy particles of Fat and Oily matter. And that such particles abound in Brimstone, we can demonstrate by this that it is very inflammable; for it is evident, that soft and thin particles, are the first of all others put in motion, and snatch'd away by the Fire. Sulphur therefore is a Mineral Juice, consisting of the most soft and minute Branch-like particles of Fat and Oleaginous Matter, easily inflammable, and generated in the Caverns of the Earth.

By the Name of **MERCURY** we understand *Quicksilver*, or an opaque and ponderous Liqueur, consisting of thick, slippery and smooth particles; whose Nature shall be explained hereafter.

Metals are commonly reduced to six species, as was before mention'd, viz. Gold, Silver, Copper, Iron, Tin and Lead. To which some joyn Mercury or Quicksilver, which tho' it be liquid in its Natural state, and Proteus-like changeth it self into all forms; yet may it be made solid, and that several ways; as when it is held over the Fumes of Molten Lead, &c. The Astrologers seem to favour this Opinion, viz. That Quicksilver is a Metal, who, as they appropriate Gold to the Sun; Silver to the Moon; Iron to Mars; Copper to Venus; Tin to Jupiter; and Lead to Saturn; so they attribute Quicksilver to Mercury, and do own its Virtue to be deriv'd from the Influences of that Planet.

To the end we may more clearly discover the Original of Metals, it will be of use to suppose, that in the Inward part of the Earth there are certain fluid Bodies, whose particles do not stick so close together, but that they may be easily dissolved: Such as are some Earthy Juices, which being generated in the deepest Bowels of the Earth, and consisting of the thickest particles of the upper part thereof, do fall down thicker by the force of the Globuli of the second Element, which by pressing them makes them heavy, and by passing through the Pores, wherewith they abound, somewhat agitates and makes them less, and so reduceth them to two kinds of Figures. For the Particles whose Matter is more solid, as those of Salt are, being intercepted, and, as it were, hammer'd in those Pores, of round and stiff, are made plain and flexible: Much after the same manner, as we have said, that a Rod of Red-hot Iron is hammer'd into a thin longish plate. And forasmuch as these particles, being agitated by the force of Heat, do this way and that way creep through these pores, by dashing and rubbing against their hard Sides, they become sharp like so many little Swords, which then constitute sharp, sourish, and corroding Juices. But the more soft particles, as are those of Fresh water, and the like, being in the said pores wholly crush'd and bruised, are reduced to so great a thinness, that by the Motion of the first Element, they are divided into many very small and extremely flexible little Boughs, which lying upon one another, are moved by a slow and creeping motion.

Forasmuch therefore as Metals are solid and heavy Bodies, it is evident that they cannot consist of the outward Crust of the Earth, which is softer than the other parts. For tho' the uppermost part of the Earth consists of Ramous or Branchy parts, which

VII.

What Sal-
phur is.

VIII.

cury is.

IX.

The number
of Metals.

X.

The vari-
ous Juices
that are
in the
Bowels of
the Earth.

XI.

Metals are
firm'd in
the inward
parts of
the Earth.

which are firmly joyn'd together; yet because there are many Intervals between them, which may be taken up by the *Air*, or other *Bodies*, and by their agitation are an obstacle to Solidity, which is the Property of *Metalline Particles*, it is necessary that they should be generated in the more inward parts of the *Earth*, which are more close, hard and compact. So that it seems probable that these *Metals* are hid, and cannot be reached or come to, by reason of the Depth of the *Earth*, and the store of *Water* that is about them, which those that go to search for them cannot fail to meet with.

XII.
How the
Particles
of Metals
are con-
veyed to
the out-
ward part
of the
Earth.

But seeing, that besides the *Vapours* which exhale from the *Waters* that lye hid under the *Earth*, there are also many *sharp Spirits*, and *oily Exhalations*; and likewise *Vapours* of *Quicksilver*, which can carry along with them, from the inward part of the *Earth*, the particles of other *Metals*, and with them ascend to the outside of the *Earth*; by this means these *Metalline Particles* being brought to the surface of the *Earth*, do there stop between the *Sand*, and constitute *Veins* of several *Metals*. For it is probable, that the Reason why any *Metals* come within our reach is, because the foresaid *sharp Juices* flowing through the passages of the inward parts of the *Earth*, do separate some of its particles from their fellows, which being wrapt up in some oily Matter, are afterwards easily carried upwards by *Quicksilver* rarified by *Heat*, where they constitute several *Metals*, according to the diversity of their magnitudes and figures.

XIII.
The distin-
tion and
diversity
of Metals,
depends on
the differ-
ence of
their Parts.

For nothing else is required to the Distinction of *Metals*, than the changing of their parts, or a different ranging of them: Because *Bodily things*, whose parts are of the same bigness, and alike ranged, are to be accounted the very same things; their distinction only proceeding from the various contexture of their Parts, as when by the accession of new Parts others are thrust out of their places, or they become otherwise ranged. And thus those particles that have long and round, as also smooth and slippery Figures, which because of their weight lye one above another, and are moved only by the Matter of the First Element, that fills up the Spaces between them, do constitute *Quicksilver*. For this is nothing else, but a very heavy and opaque Liquor, consisting of such thick Particles as are long, and round like a Pillar, and very smooth; which tho' by reason of their weight they lye one upon the top of another, yet are easily moved by the *Aethereal Matter* that fills their Pores. And so likewise those Parts which are so firm and fix'd, as that they cannot be changed by any *Fire*, or consum'd by any *acid Spirits*, constitute *Gold*. Thick and Branchy Particles, whose surfaces lye close together, and whose Pores are only penetrated with the striate Matter, make *Iron*. And so for the rest of the *Metals*, which derive their distinction from the different magnitude and figure of their Parts.

XIV.
Transmuta-
tion of
some Me-
tals is
possible.

For this Reason some have believed the Transmutation of *Metals* to be possible, since it is notorious that *Iron* may easily be changed into *Copper*: For if *Iron* be cast into *Copperas* or *Vitriolick Water*, its outside is thereby turned Red, which Red powder being frequently scrap'd from it, and melted down, becomes true *Copper*. The same Transmutation is also effected by some Foun-

tains; as by that which *AGRICOLA* mentions, near *Smelnitz*, the *Water* whereof being derived into three Channels rang'd in order, in which pieces of *Iron* are laid, they are thereby changed into *Copper*; and the small scales of *Iron* are so corroded by this *Water*, as to become like *Clay* or *Dirt*. All which afterwards being melted down, becomes pure and good *Copper*. It is manifest also that *Quicksilver* may be chang'd into another *Metal*. For if after you have reduc'd *Lead*, or *Litharge*, to *Ashes*, you pour the *Flegm* of *Vinegar* upon it, and afterwards pour some drops of this *Vinegar* upon *Quicksilver* dissolv'd in strong *Water*, it will presently be precipitated to the bottom of the Vessel in the form of a Powder, which being melted down becomes *Lead*.

But the Question is, Whether Imperfect *Metal*, by Example *Quicksilver*, can be turn'd into *Gold*? This the *Chymists* confidently assert, and take for their Vouchers, *RAYMUND LULLY* and *ARNOLDUS de Villa Nova*; who, they tell us could do as much. But I take all this to be no more than *Lies* and *Stories*: Or if ever they did make *Gold*, that this Effect was not to be attributed to their Art, but to meer Chance. And indeed it is a thing as unlikely, as if a *Man* having broke his *Hour-Glass*, should so dexterously throw the Sands of it upon a *Table*, that the grains of it should be ranged into the figures of such Letters as should make up some Verses of *Ovid's Fastorum*. For since we are ignorant of the precise bigness and figure of those Particles that enter the Composition of *Gold*; as well as of the way of knitting them together, so as to make one Body of them; we may well conclude, that to make *Gold* is a thing morally impossible.

It is a Property of *Metals* to be Ductil, and more especially of *Gold*, a small quantity whereof may be beaten or drawn out into a vast extent. For out of one Broad piece of *Gold*, a vast number of Leaves may be beaten, 5 or 6 whereof are sufficient to cover a piece of *Silver*, of a Cylindrical Figure; which being drawn into a fine Thred, the *Gold* is coextended with it, there being no part of the *Silver-thred* to be seen which is not gilt. The reason of this Ductility in *Metals* is, because the particles of *Metals* are of a Longish figure, and are so disposed, that they lye upon one another according to their whole surface; which makes, that when they are prest under the Hammer, or in Drawing, they fall down sideling, and joyn side to side without any separation. Thus it comes to pass, that *Metals* under the Hammer, may be extended into length and breadth, still retaining the firm cohesion of their parts; and the same is the Cause of their ductility into Threds.

Metals are subject to Corruption by *Rust*, and more especially *Iron*. Which is an Argument, that its particles are not more solid than those of other *Metals*, tho' they be Thicker; but that it abounds with Pores. And because these Pores after Infusion grow less, therefore it is that *Steel* is not so easily penetrated by other Bodies, as *Iron*, and consequently, less subject to *Rust*. Now *Rust* is nothing else, but a perturbation of the Parts of *Metals*, caused by the Exhalations of a greatly agitated Sulphureous Liquor, the particles whereof thrust themselves into the Pores of *Metals*, and stop the Orifices of them.

XV.

It is mo-
rally im-
possible to
make
Gold.

XVI.

Ductility
is a Pro-
perty of
Metals.

XVII.

Metals are
subject to
Rust.

XXIII.
The Sun is
the Efficient
Cause
of Metals.

The Efficient Cause of all Metals is the Sun, whose heat pierceth through all the Passages and Pores of the Earth. For tho' the Action of Light be nothing else, but a kind of Pression, whereby the Sun pulseth the subtil Matter to Right Lines, that reach from his Body to the Earth; yet the Terrestrial particles being agitated by his heat, do continue in their motion, except some intervening Cause do chance to hinder them. Hence it is we perceive, that the Heat which the Light hath left upon the surface of the Earth, doth continue for some time; so that it is no wonder, if from thence by degrees it proceeds to the Bowels of the Earth, because the Terrestrial parts that are struck by the Sun-beams, do move those that lye next to them, and they again their Neighbours, till the Heat at last be derived to the most Inmost parts of the Earth. After the same manner as a mans Head cover'd with a Hat, tho' it be not enlightned by the Sun, yet is sensible of its heat, even after that the Sun-beams do no more beat upon it. And thus much shall be sufficient to have spoken of the Nature of Metals, their Original and Affections; we proceed now to the Minerals.

XIX. MINERALS, are Bodies made up of Salt, Sulphur and Mercury, mingled in a certain proportion with Aqueous and Terrestrial particles, and excocted or brought to perfection by means of Subterraneous fires, or the Sun's heat, and digg'd out of the Mines of the Earth. Wherefore also they are called Fossils.

XX. There are Three kinds of Minerals: 1. Mineral, or Coagulated Juices: 2. Mineral Earths: 3. Stones.

XXI. Coagulated Juices are Mineral Bodies, compounded of sharp and oleaginous Juices, mingled with a more gross Earthly Matter, endued with a strong taste or smell, and easily soluble in Water or Oil. The chiefest of this kind are Salt and Sulphur.

XXII. Mineral Earth, is a Body dug out of the Earth, consisting of Terrestrial Particles, joyned with a tough and viscous Humidity, reducible to Powder, and soluble in Water, so as thereby to be turn'd into a kind of Clay. Wherein it differs from Mineral Coagulated Juices, which are wholly dissolv'd in Water, and are not turn'd into Clay by admixtion of the Aqueous particles.

XXIII. These Mineral Earths are various, according to the diversity of the Particles whereof they consist; or of the Juice, whereby their Parts are joyned together; as also of the Country where they are found. For if the Matter be very tough, ropy and unctuous, it makes Potters-Clay; if it be tough, white and dug up in the Isle of Crete, it is Chalk; if in the Isle of Samos, Samian Earth; if a yellow Colour, Oker; if Red, and found in the Isle of Lemnos, Lemnian Earth, and Sealed Earth, because it was used to be sealed with the Seal of Diana's Priest; if it be of a pale Red, and digg'd in Armenia, 'tis call'd Armenian Earth, or Bole. What Stones are, shall be delivered in the next Chapter.

XXIV. Minerals are not generated, like Metals, in the Inward parts of the Earth, where they have the whole weight of the Earth lying upon them; but about the surface of it, where its Parts are separated by infinite Chinks and Crevisses, by

which they give a free passage to Vapours and Exhalations, and to other particles of that Matter, which the Heat contain'd in its Bowels hath put into motion. And forasmuch as it is peculiar to Exhalations, to mingle themselves with the smallest particles of the Earth they snatch along with them, they by this means come to form certain little Lumps or Masses, which after various agitation acquire also the same motion; but that ceasing, they are all at last brought to a state of Rest, being clothed with a roundish Figure. And after this manner 'tis probable that the Grains of Sand are formed; which are Heavy, because they are compacted of Terrestrial Matter; Hard, because they are without motion; and Transparent, because they have Pores that transmit the Globuli of the second Element to right Lines, in the very same manner as they were moved, before that the Particles of Sand were yet Coagulated.

Tho' every single grain of Sand be transparent, nevertheless where many of them meet together, so as to make a Heap, they constitute an opaque Body; because in this state they cannot give a free passage to the Light, seeing that each surface reflects some Rays of it. Thus the Powder of Glass is not Transparent, because the various particles of Glass cannot have their pores so corresponding with one another, as freely to transmit the Light. Thus the Grains of Sand, especially those of the Indies, when beheld through a Microscope, be transparent, and resemble Diamonds; yet when they lye in heaps, they can no longer give free passage to the Light, and therefore constitute an opaque Body.

Potters Clay, notwithstanding that it is tough and fat, yet is produc'd much after the same manner as Sand; only with this difference, that the Grains of Clay are much less, which make their Intervals not to let in water so readily, nor indeed without some force.

If the Particles of Salt and Oil, which continually ascend from the Inward parts of the Earth, were always like one another, we should every where meet with the same kind of Sand and Clay: But it being very probable, that the said Particles of Salt and Oil, are not in all places the same; it is to be of no matter of Wonder to us, that the Clay and Sand likewise is not always the same, but differing in Colour and the Magnitude of their Parts.

CHAP. IX.

Of the Generation of Stones, Common and Precious, and of their difference and distinction.

STONES are Mineral Bodies, hard, and compounded of a petrifying Juice, and Terrestrial Particles, not subject to Fusion, but calcination by Fire; nor malleable, but breaking to pieces under the stroke of the Hammer. These, according to the Purity or Impurity of the Matter whereof they consist, are divided into Common and Precious, which are either generated in the Bowels of Animals, or without them.

Some

XXV.
The Pellucid Grains of Sand being heap'd together, make an Opaque Body.

XXVI.
How Potters Clay differs from Sand.

XXVII.
The reason of the difference of Clay in several parts.

What Common Stones are.

II.
New Stones
are daily
generated
in the
Earth.

Some are of Opinion, that there are no *New Stones* produced, but that all of them were created at the Beginning. But *Miners* assure us to the contrary, who often find *Stones* in those places, where before was nothing but *Sand* or *Clay*. Whence it is obvious to conclude, that both these are the matter of *Stones*, and that of the particles thereof variously joyned and mingled together, they are compounded. For tho' things made of *Sand* be hard, and cannot be softened; yet this nothing hinders, but that by the help of some *Terrestrial matter*, filling their *Pores* and *Intervals*, they may so hang together, as to constitute *Stones*. Thus it frequently happens, that *Waters* running through the *Earth*, do carry away with them some small particles of the *Stones* through which they run; which *water* coming afterwards to places where its Current is very slow, may give occasion to those particles to unite together, and constitute a *Stone*.

III.
A twofold
Rise of
Stones.

Stones may be made of *Sand* these two ways; first, out of *dissolved Sand*, as when *Sand* dissolved in any quantity, is afterwards hardened. And the *Stones* thus formed are transparent, as the single grains of *Sand* are, and are of various figures, according to the Compression of the Bodies that are lying about them. The other way is, when *Stones* are made of *solid Sand*; as when a great heap of grains of *Sand*, by the intervening of some *Exhalation*, do grow together: This way all *opaque* and *rough Stones* are made; which are proper for the grinding of *Iron*, and polishing of other *Stones*.

IV.
That there
is such a
Matter
wherewith
the parts
of Stones
are knit
together.

It is not to be doubted, but that much of this Matter is sublimed towards the surface of the *Earth*, in the form of such *Exhalations* as accompany the rising *Vapours*. This is evident in many *Fountains*, which notwithstanding that the *water* of them being very clear to the *Eye*, yet contains great store of them, which meeting and joyning together in some Parts, become sensible. Thus there is a *River* in *Auvergne* in *France*, which doth so abound with these *Exhalations*, that the Channel of it is become *Stony*, swelling by degrees higher and higher. In like manner there are found some *Springs* which cover the *Channels* and *Conveyances* by which they pass, with a Crust of *Sand-stone*. And there is one at *Rome*, which stoppeth the *Pipe*, through which its *water* passed, with *Alabaster*.

V.
How Mar-
ble is
formed.

The production of *Marble* doth not at all differ from the production of other *Common Stones*; save only that the *Clay* whereof it is made consists of lesser particles, and hath straiter *Pores*, which for that Reason are more easily fill'd with those *Exhalations* that stick to the Sides of them. And this makes the Composition of *Marble* more accurate, and the Texture of its parts more close and compact, than the common mixture of *Stones* is. Which may be easily gather'd from the smoothness of its surface, seeing that the Roughness of *Sand-stones* and *Pumice-stones*, and other such like, proceeds only from their *Cavities*. Now *Marble* is polish'd with *Sand*, by the rubbing whereof its prominent particles are worn away. In this Polishing, *Water* also is made use of; which being mix'd with the *Sand*, doth by this means more easily insinuate it self into the pores of these Particles, that are to be rubb'd off. There are several

sorts of *Marble*, some being *White*, others *Black*, some *Transparent*, and some *Opaque*; all which diversity proceeds from the various Contexture of their Parts.

For *Transparent Stones* are generated, when the *Exhalations* and *Vapours* being first changed into *Juices*, in the Chinks or Cavities of the *Earth*; afterwards by the departure of those fluid Particles, do come nearer together, and by degrees so cleave together, that the Globuli of the second Element have free passage through their pores, in order to the Transmission of the Action of *Light*. And on the contrary *Stones* become *Opaque*, when the *Vapours* that are shut up in the narrow Chinks and Clefts of the *Earth*, are there stopt, and become so mingled with the *Earthy particles*, that the pores, in many places, are not wide and open enough to transmit the *Light*.

There are many kinds of *Common Stones*, viz. *Marble*, *Flint*, *Touch-stone*, *Whet-stone*, *Pumice*, and *Sand-stone*; *Stones* in the Bladder or Reins; *Talck*, *Load-stone*, &c. Of *Marble* we have treated already.

Flint is almost the hardest of all *Stones*, and is commonly Round, and somewhat Flat, like *Lentiles*, and being dash'd against another, divides it self in two little *Hemispheres*. Because of its extreme hardness it is apt to leap back or rebound, since it neither yields, nor can be easily reduc'd to Powder. Its production is much like that of *Marble*, being found buried in *Clay*, as in its Matrix, whose pores being fill'd with the said *Exhalations*, procure it the great Hardness it hath.

Touch-stone belongs either to *Marble* or *Flint*. It admits of the most perfect Polishing, and is sometimes found very exquisitely smooth'd by Nature. For which Reason also it is very hard, and doth not admit any Division without difficulty.

A *Whet-stone* has a Roughness, which conduceth to the Smoothing and Grinding of *Glass* and *Metal*; in which Operation *Water* is sprinkled upon it: For the *Water* being pour'd over it, smooths and makes even the more sensible Asperities of the *Whet-stone*, and hinders it from acting too boisterously upon the Body that is to be Ground.

Pumice-stone is a *Stone* of an Ash colour, full of great Cavities like a *Sponge*, into which it admits Moisture, but soon lets it go again. It is made use of for the Polishing of *Marble*; for by its Roughness it reduceth the prominent parts of *Marble* to smoothness.

The *Sand-stone* is formed in *Holes*, from whence the intercepted Matter derives its smoothness. Its Colour is white; because its particles are so dispos'd, as to reflect or send back the Rays of *Light*, in the same manner as it hath received them. Wherefore also it appears in the likeness of *Froth*. Tho' it be very Light, yet doth it not swim upon the *Water*; but the moisture entering into its pores, it sinks immediately.

Talck is a *Stone* that is *Transparent*, except it be too thick; for then it is *opaque*, by reason of the multiplicity of Surfaces heap'd one upon the top of another, and whose pores do not correspond exactly enough for the Transmission of *Light*.

XIV. *Stones form'd in the Body of Man.* A Stone in the Body of Man, is formed in like manner as other Stones are, viz. by the Coalition of Sand, by means of some slimy Matter in the Reins or Bladder. It commonly inclines to a reddish Colour, and according to the different disposition of the Sand, is either smooth or rough; as we see that Stones that lye at the bottom of Rivers, are some of them smooth, and others very rough and uneven.

XV. *What precious Stones are.* Precious Stones, are Bodies small in bulk, of a hard and strong substance; which either are Transparent, or of a lustrous Colour.

XVI. *How precious Stones are generated in the Earth, and first of such as are transparent.* Gems are generated, not of a company of Sands grown together, as the Common Stones are; but of a certain fluid Matter, which only constitutes one grain; provided there be but so much of it, as to make some sensible Bulk, and such as is sufficient for a pellucid Body. Because that when the Exhalations that in the Clefts and Cavities of the Earth are gather'd into a Drop, by the loss of their slippery and fluid Particles, begin by little and little to cleave to one another, the Globuli of the second Element can on all sides freely and strongly enough pass through their pores; which could not be, in case they did consist of many grains: For how soft soever they might afterwards come to be, yet they could never be so joyned, but that there would be some Interruption, which would spoil their Transparency. And therefore these kind of Exhalations, according to the different degrees of their Hardness, and the various disposition of their Parts, are turned into Stones; as into Crystal, Diamonds, and the like. There is no difference betwixt a Crystal and a Diamond, save only that the particles of a Diamond are more closely knit together.

XVII. *Of Colour'd Gems.* But if it so happen, that any Metalline particles be mix'd with this matter, that is common to all precious Stones; this causeth some modification of the Light that passeth through them, so that it produceth in us the sense of divers Colours; and thus instead of a Diamond or Crystal, we shall have several kinds of precious Stones, as Saphirs, Chrysolits, Jaspers, Agats, and the like.

XVIII. *The several kinds of Precious Stones.* Precious Stones therefore are divided into Transparent and Colour'd. The transparent are Crystal, the Diamond, and the Beryl, which have their Parts so ranged, as to leave Intervals, through which the Globuli may transmit their Action to Right Lines. The most precious of these is the Adamant, being of an exceeding Hardness, because of the close coherence of its Parts. Yet is not its Hardness such, as to be of proof against the strokes of a Hammer, as some relate, seeing that it may be grinded into Powder. So likewise the Common Story of its becoming soft in the Blood of a Goat, is no better than a Fable; and that it cannot be hurt by the Fire: All which Experience hath condemn'd of falsity.

XIX. *Crystal.* Crystal is of an Hexagonal figure; for every particle of Crystal being surrounded and kept in by six others, it must necessarily admit of a six Corner'd figure. There are some that affirm, That Crystal by the strength of the Fire can be melted; whereas others assert the contrary, and that after utter Diligence used, they could never bring it to Liquefaction. Some of the Ancients believ'd, that Crystal was the effect of extream Cold; but this is a vain Imagination, for all confessing Crystal to be

a Stone, we cannot attribute its Coagulation to Cold. DIO DORUS was better advis'd, who Lib. II. tells us, that Crystal is a Stone coagulated out of pure Water, not by Cold, but by the virtue of a Divine Fire.

The Beryl hath a great resemblance with Crystal; it is chiefly found in the East Indies, according to PLINY, at least the best and most lustrous are found there. For those we have from Babylon are of a kind of greasy Colour; yea, it is said, that there are Beryls found in Germany of the Colour of Oil.

The most Noble of all the Colour'd precious Stones is the Carbuncle, of a Red colour, and resembling the flame of Fire.

The Chrysolite is a Gem of a Golden colour, whence it took its Name; transparent and very hard.

The Hyacinth is of a Yellow colour, resembling the lustre of Gold.

The Emerald is the most precious of all Gems, and well nigh the most Brittle too, for it is easily broken. It is of a Green colour, like Grass.

The Topaz approacheth to the Colour of an Hyacinth; tho' some do say it is of a Green colour. It is said, that when it is laid under the Sun-beams it represents a Star; which is rather the effect of its form and colour, than of any peculiar Nature.

The Turcois is a precious Stone, of a Sky colour mixt with Green.

The Amethyst is much of the same softness as Crystal, and is found in the same place. It is of a Violet Purple colour, very grateful to the sight.

The Gem Morion, is of a very Black colour.

The Agate admits of all Colours, as having white, black, and other variegated streaks in the midst of it. And by this diversity of its colours, it is represented of divers kinds, by those who have a mind to deceive the Buyers.

The Jasper is a Green stone, with the mixture of Bloody spots. The best are those that come from the East.

The Ruby takes its names from the glorious Red colour wherewith it sparkles.

The Granat is also of a Red colour; but with some mixture of a Yellow; so called, because of its likeness to the grain of a Pomegranate.

The Onyx is the Alabaster of the Ancients, but much more precious than that which we commonly call so; it resembles the colour of the Nail of a Mans Hand, with some Veins running through it, which imitate the colour of a Jasper.

The Saphire exceeds the other Gems in Beauty, and is of a Sky Blew colour, resembling the lively colour of the Sky, by its wonderful lustre; and extraordinary perspicuity. It is the hardest of all precious Stones, next to the Diamond.

There are also other Stones which are reckoned amongst the Precious, as the Pezair, or Bezoar, Pearls, Chelidonius or the Swallow-stone, &c. But these do not seem to deserve the name of Gems; because the Pezair, which is found in the Stomach of a Beast called Pezaim, is too soft to deserve that name. Pearls which are found in the shells of Oysters and Muscles are of too dark and faint a colour, and without transparency. And the Swallow-stone, which is found in the Stomach of Swallows, hath nothing in the least in it that resembles a Gem.

C H A P. X.

Of the Load-Stone, and Electrical Bodies.

I. **T**HO' the Load-stone be reckon'd amongst Common Stones, yet doth not the Earth produce any thing more wonderful than it, the effects whereof, as they were matter of Astonishment to the Ancients, so do they still puzzle the Brains of the Greatest Philosophers. This wonderful Stone is compounded of thick and branchy Particles of the Earth, approaching to the Nature of Iron; since there is no Iron Ore, which hath not much Earthy matter joyn'd with it; nor any Load-stone, which doth not enclose more or less of Iron. Yea, so great is the affinity between the Load-stone and Iron, that they are both digged out of the same Mines; and if we will take the word of GILBERTUS, the best Iron is got out of the Load-stone.

II. The Load-stone therefore is a Stone, resembling the Matter that constitutes the Middle part of the Earth, which having Pores from one of its Poles to the other, fitted for the free passage of the striate Matter, can turn it self towards one of the Poles of the Earth. It is said to resemble the Middle part of the Earth; because the Load-stone, of all other Stones, seems to be of the same make and composition with the Middle part of the Earth. By the striate Matter mention'd in the Definition, we are to understand the Matter of the first Element, twisted in the manner of the Tendrils of a Vine or Ivy-Bush. It is said, that it can turn it self to one of the Poles of the Earth; because a Load-stone being left without impediment, always turns it self to the Poles. Iron is a Metal of Affinity with the Load-stone, endued with Pores, accommodated for the free passage of the striate Matter, by which means it is able to turn it self to the Poles of the Earth.

III. The Virtues of the Load-stone may be referr'd to three Heads; whereof the First is, that being in a free position without any thing to hinder it, it spontaneously directs it self to the Poles of the World. Secondly, That it draws Iron or another Magnet to it self, and sometimes also repels the same. Thirdly, That by a Touch it communicates to the Iron, as well the virtue it hath of pointing to the Poles of the World, as that whereby it draws Iron.

IV. For the better understanding of these Virtues of the Load-stone, we are to suppose in the First place, that the Heavenly matter is the Principle of all the motions of the World; which, as it consists of most subtil and thin parts; so it easily penetrates the Pores of all Bodies, and according to the different degree of its agitation, doth put them into motion, and push them forward; and being fluid, doth accommodate it self to the narrow Spaces through which it passeth, and puts on various Figures, according to the diversity of their situation; so that its particles which pass through the Triangular Spaces, which are left in the midst of three Globuli of the second Element touching one another, must take upon them a Three-corner'd figure, which we may conceive as so many little Pillars, with three hollow'd Channels, winding like a Screw. And this more or less, as they pass

neater to, or further from the Axis of the Vortex, because the Globuli of the second Element move more slowly in the former part of the Vortex, than in the latter; as it hath been declared more at large in the Fifth Part of this Institution.

We are likewise to Note, that because the Striate particles come towards the Middle of Heaven from contrary Quarters; that is, some of them from the South, and others from the North Pole; whilst in the mean time the whole Vortex is moved one and the same way; therefore those Particles which come from the Southern Pole, cannot have their Screw turn'd the same way, as those which come from the Northern Pole, but the quite contrary.

Again, we are to suppose that in the Region of the Earth C A D B, there are many Pores parallel to its Axis, through which the Striate, or Screw-like Particles, coming from the parts about one Pole, may pass freely to the other opposite to it; but forasmuch as they are writ'h'd a contrary way, and that the one go one way, and the other quite opposite, the Pores which admit the Striate particles that come from the South Pole A, will never be able to receive those that proceed from the North Pole B. Whence it comes to pass, that those Particles that proceeded from one Quarter, can never return by the opposite part, because of the different writhing of the Pores, and because of several most minute fibres arising in them, which obstruct their return. So that after the Striate Particles have run through that Great Load-stone, the Earth C A D B, in Right Lines, or equivalent to such, from one Hemisphere to the other; or from the North B to the South A, or else quite contrary from A to B, they are forced to return to the same Hemisphere through which they at first entered the Earth.

So that about every Magnet, as well as about the Earth, C, A, D, B, a perpetual Vortex of the Striate Matter, which is manifest from this Experiment, that if you cast the filings of Iron or Steel round about a Load-stone laid upon Paper, the said filings will dispose themselves a-round the Load-stone in manner of a Vortex. Wherefore if you shall direct the North Pole of a Load-stone you hold in your hand, to the North Pole of another Load-stone plac'd upon a piece of Cork in a Basin of Water, the North Pole of the later Magnet will turn away from that you have in your hand. But when the Load-stone placed on the Water, being turned about, directs his South Pole to the North Pole of the Magnet in your hand, then it will approach to it, because the interjacent Air being driven away by the Striate Matter, the Loadstone is also push'd forwards by the Air that surrounds it. Whence it is that the Poles of a Loadstone are said to be of a contrary virtue.

And if by chance the Striate Particles, in passing from one Hemisphere to another, do there meet with the Load-stone I, K, L, M, N, forasmuch as they find in the same, Pores ranged in the same manner, as the Pores of the inward part of the Earth, they easily and freely pass through them; especially if the Load-stone be so posited, as to have the arrangement of his Pores turn'd towards that quarter, from whence the Striate Particles proceed.

V. The Striate Particles are variously crook'd and turn'd.

VI. How the Striate Particles, that proceed from the Earth, do affect the Load-stones that come in their way.

Figure 41.

VII. About every Magnet a Vortex is formed, as about the Earth.

IX

X

XIX

More

VIII.
The Striate
Particles
do not so
easily pass
through
the Air or
Water, as
through the
Earth.

Moreover we are to observe that the *Striate Particles* cannot pass so freely through the *Air* or *Water*, as through *Iron*; for they being *fluid Bodies*, their parts cannot always keep the same situation, and therefore if at any time such *pores* come to be formed in them, they are presently again spoil'd and confounded by the continual agitation of their *Parts*. Those *Bodies* only are disposed to admit the *Striate Particles*, that consist of *Thick* and *Branchy Parts*, such as rationally we may believe *Iron* and *Steel* to have. For of all *Metals*, none is either with more difficulty melted in the *Fire*, or extended under the *Hammer* than *Iron* is, or made *harder* without the addition of any other *Body*: which three instances abundantly shew, that the *Particles* whereof it consists must be *Angular* and *Branchy*, which is the reason they are so closely knit together, this being the most necessary condition in order to the free transmission of the *Striate Particles*. For we find that *Iron* temper'd and hardned, doth more freely afford them passage, than other *Iron*; and so likewise 'tis observed, that when the *Iron* is smooth and burnisht, the *Striate Particles*, that proceed from one *Pole* do more orderly return to the other.

IX.
In every
Magnet are
two Poles,
an Axis,
and Parallel
Lines.

Figure
42.

For the better understanding of this *Magnetick* virtue, we are to take notice, that in every *Load-stone* there be 2 *Poles*, *South* and *North*. The *South Pole* is the *Point A*, being the middle of that part wherein are the *Orifices* of the *Pores*, by which that *Striate matter* enters, which comes from the *South part* of *Heaven*: and the *North Pole* is the middle of the other part, by which these *Striate Particles* go forth, and others coming from the *North F*, do enter. Besides the *Poles*, considered in a *Load-stone*, there is also its *Axis*, or the *Diameter* from the *North point F*, to the *South A*, drawn through the *Center* of the *Load-stone*. And lastly, its *Parallel Lines*, which being drawn from the *North* to the *South*, are at an equal distance from the *Axis* of the *Load-stone*.

X.
Why the
Magnet
points to
the Poles of
the Earth.

These things being premised, it will not be difficult to explain, why a *Load-stone* turns its *Poles* to the *Poles* of the *Earth*; because the *Magnetick* *Particles* coming from the *North Pole F*, and *South B* of the *Earth*, rushing obliquely against the *Poles* of the *Magnet*, do push it this way and that way, till that they can freely, that is in right lines, pass through its *Pores*.

XI.
How one
Load-stone
turns to
another.

And it is for the same reason that one *Load-stone* turns to another. But it is to be observed, that the *South pole* of the *Magnet* always turns to the *North pole* of the *Earth*, or of another *Load-stone*; because the *particles* that come forth from the *South pole*, are writhed another way than those that enter. Whence it is that the *Poles* of the same denomination do always flee from one another. As for instance, suppose we that the *Poles* of 2 *Magnets* be turned to the *North Pole* of the *Earth*; these 2 *Poles* are of the same Denomination, because the *Particles* that flow from the *North Pole* of the *Earth*, do act upon them after the same manner; but it is apparent that these *Poles* flee one another, and therefore would flee from the *Pole* of the *Earth* also, in case they were of the same Denomination with it.

XII.
A Load-
stone flees
from ano-

For the same Reason it is that a *Load-stone* being set on one end on its *North Pole*, and swimming on a piece of *Cork* in the *Water*, if to the *South Pole*

of this *Load-stone*, the same *Pole* of another *Load-stone* be applied, the *Cork* flees away from it; for seeing that the *Particles* cannot enter those *Pores*, they require some space, in the which turning themselves, as in a *Vortex*, they may return to their *North Pole*.

When the *North Pole* of one *Load-stone* is turned to the *South Pole* of another, and that the *Spheres* of both of them become one, then they approach to each other; because in this case they act with their joyn't forces upon the *Air*, and therefore make it withdraw; which, by its *Circulating*, pulseth on both the *Magnets* till they come to touch one another.

But some, it may be, will demand, Why for the same Reason the *Poles* of the same denomination do not as well come together; or, why the *Magnet* doth not approach to their *Bodies*, seeing that the *Air* in both cases is alike prest upon?

The Answer to this is obvious, for the *Magnetick* *particles*, because of their different way of wreathing, finding no fit passages for themselves in the *Pole* of the same denomination, do greatly hinder this *Conjunction*. And the same is the reason, why it doth not draw near to other *Bodies*, since the *Magnetick* *matter* doth not find any corresponding *Pores* in them.

From what hath been said, it will not be difficult to explain, how a *Load-stone* draws *Iron* or *Steel*; or rather how a *Load-stone*, *Iron* and *Steel* draw near to each other: by saying that the *Load-stone B*, attracts the *Iron C*, because both their *pores* are so disposed, that the *striate matter A*, which comes from about the *Poles* of the *Heaven*, and continues its course through the *pores* of the *Earth*, that are parallel to the *Axis* thereof, passing more easily through the *pores* of the *Load-stone B*, and of the *Iron C*, than of other *Bodies*, drives away the intermediate *Air*. Now because the *Air* finds no place (for there is no *Vacuum*) to which it might pass, but that which is left by one of these two *Bodies*; it cannot be otherwise, but that the *Load-stone B*, must be push'd towards the *Iron C*, or the *Iron C* towards the *Load-stone B*. For this is a General Rule, That the *Virtue* of the *Load-stone* is increased or diminished, according to the approaching or withdrawing of the *Iron*. It is increased, when the *Load-stone* and *Iron* are so disposed, as that the one sends its *Striate particles* into the other; but diminished, when the *Iron* is withdrawn from the *Magnet*, or the *Magnet* from the *Iron*. For the *Communication* of the *Striate matter* being by this means removed, their force must needs be weakened and lessened.

This will not be hard to conceive, if we take notice, that the *Parts* of the *Air*, as of all other *fluid Bodies*, are in continual motion, and that therefore of necessity they must push continually towards the *Load-stone B*, which they surround on every side: And because they equally push it forwards on all sides, they do not push it more one way than another. But when the *Air* is driven out of its place by the *Striate matter*, proceeding from the *Magnetick Body* at *A*, it so happens that the *Magnet* is less push'd forwards on that side, than on the other, and so approacheth to the *Iron C*, or on the contrary.

forwards
a Body.

Where-

XVII. Wherefore the Sphere of Magnetical Actions is conceived to be about the Circuit D E, within which the Striate particles, composing the Vortex from F to G, can affect Bodies that have their Pores dispos'd alike. And this Sphere is by so much the greater, as the Load-stone is bigger, or at least the longer it is; because the Magnetick matter, passing through the longer Pores of it, thereby acquires the force of passing farther in a strait Line in the Air; which makes, that the Virtue of great Load-stones doth reach farther than that of small ones.

XVIII. Hence it appears, that the Load-stone B, cannot properly be said to draw the Iron C; because in this Action there is no Attraction at all, but as soon as the Iron C, is placed within the Sphere of the Activity of the Load-stone B, it gets strength, and is carried towards the Magnet; which Action doth not so much deserve the Name of Attraction, as that of Circumpulsion, or of being push'd forwards on all sides.

XIX. There still remains one Difficulty behind, which is this: If there be so great a Correspondence betwixt the Pores of a Load-stone and Iron, how comes it to pass, that the Load-stone A B, armed with Iron; that is, to which the Iron Plates C D, and E F, are fastned, should carry much more Iron, than one that is bare. To which I return this Answer, That this greater Force or Virtue, doth not proceed from the Iron that is fastned to it, but from the contact of it; because the pores of the Iron Plates C D, and E F, do exactly answer to the Pores of Another Iron, and their Parts are so joyned, as to appear immediately to touch one another. Whence it is that the Striate matter passing through these Pores, from the Iron fastned to the Load-stone, to another Iron b a, doth with more ease drive away the intermediate Air, and make them more closely cleave together. Now the Pores of the Magnet, cannot so immediately agree with the Pores of the Iron, by reason of its Impurity and Stony Nature. Which makes, that there is always some Interval between the Load-stone and the Iron, by which the Striate matter doth remove from the Pores of the one, to those of the other.

XX. Neither doth the Contrariety of the particles of the Striate Matter, whereby those that enter at one Pole, cannot enter in by the other, hinder them from agreeing to bear up the Iron; because those that come from A, the South Pole of the Load-stone, being reflected by the Steel-plate, enter in at one part of the Iron b, in which they make its North Pole, and flowing from thence to the South Pole a, they meet with others of the Steel-plate F E, by which they mount up to B, the North-pole of the Load-stone; and on the contrary, those that go out from B, through the Plates F E, the Iron that hangs at it H G, and the other Plate D C, return to A.

XXI. Neither can any other Reason be given in my Judgment, why a Load-stone, tho' never so strong, cannot withdraw an Iron that is distant from it, from the contact of another, tho' much weaker Magnet; because tho' the Striate particles pass through both those Magnets, and the intermediate Iron, so that one only Load-stone is made of them all three; yet by reason of the Contact, and a greater agreement of the parts, the Iron cannot

be withdrawn from a weaker Magnet, to which it is joyn'd, by a stronger. Forasmuch as the Load-stone, not only joyns the Iron to it self, but over and above communicates its virtue to it.

It remains still to be explained, how the Load-stone communicates its virtue to the Iron, without any loss of its own strength and virtue. The Iron acquires this New virtue, when it hath pores fit for the receiving of the Striate Particles, and so situate, that they can freely pass through them, as hath already been said. For nothing is wanting to it towards the acquiring of this Virtue, save only that some small ends of the Branchy particles, which stick out here and there in those pores, must all of them be turned away in those pores, through which the Striate Particles that come from the South are to pass; whereas in the other pores they must be turned the quite contrary way. Now as soon as the Load-stone toucheth the Iron, the Magnetick particles rush with great force and in crowds into the pores of the Iron, and by this means bow these Extremities of the Branchy particles; and consequently contribute all that which was requir'd to the Magnetical virtue.

Hence it is, that when a Gad of Steel or Iron being Red-hot, is set to cool, with its Extremities turn'd directly North and South, it is, by reason of its contexture and pores, which the action of the Fire hath clear'd and opened, immediately penetrated by the Magnetical Effluvia's of the Earth; which continually do courie it through the Air from one Pole to another, and so becomes endued with a Magnetical property: Which doth not so happen in an Ingot of Silver turn'd South and North, and that because of the difference of its Contexture, and disposition of its Pores.

An Iron differently receives the Magnetical virtue, according to its different way of application to the Load-stone. For the part R, of the Iron R S T, if it be apply'd to the North-Pole of the Magnet P, will become the South Pole of the Iron; because the Striate particles coming from the South, will enter in by it, and the Northern will enter in by the part T, being reflected or beat back from the Pole A, through the Air. And the same part R, if it lye upon the Equator of the Load-stone, and look towards its North Pole, as in C, it will again become the South Pole of the Iron. But if it be turn'd about, and look towards the South Pole, as in D, then it will lose the Virtue of the South Pole, and become the North Pole. Lastly, If the Middle part of this Iron S, touch the Pole of the Magnet A, the Northern Striate particles which have entred into it by S, will go out again by R and T; and by this means the Iron will receive at both ends the Virtue of the South Pole, and in the midst that of the North.

It may be Queried, why those Striate particles, that from the Pole A of the Magnet, do enter the part of Iron marked S, do not directly pass on to E; but are reflected this way and that way towards R and T; so as the Iron receives the Magnetick virtue, rather according to its Longitude, than to its Latitude? The Answer to which is obvious, viz. because they meet much more free and open passages in the Iron, than in the Air; for which Reason they rebound from the Air towards the Iron.

XXVI.

A Plate
of Iron
binders
the attra-
ctive Vir-
tue of the
Load-stone.

Figure
45.

There is also another Difficulty remains to be explained. viz. how the Iron Plate D C D, being apply'd to the Pole of the Magnet A B, which, we said before, did much help the carrying or bearing force of the Load-stone, should notwithstanding hinder its force of attracting and turning Iron to it; so as to make the Point E of the Magnetick Needle E F, not to be directed to the Pole of the Magnet B, but towards the end of the Iron Plate D. To which we Answer, That the Striate particles, which, if this Plate had been out of the way, would have pass'd from B, toward E F, are diverted by it from C, towards the Extremities thereof D D, because they find a more ready and free passage for themselves through the whole length of the Plate from C to D, than through the small interval of its thickness C. To this may be added also, that the Striate particles do pass more freely through the Plate, than through the Air, so that scarcely any of them reach the Needle E F.

XXVII.

Iron is
more apt
to receive
the Mag-
netick Vir-
tue accord-
ing to its
length,
than
breadth.

Wherefore, tho' Iron be made partaker of the Magnetick virtue, yet doth it more readily admit it according to its length, than according to its breadth, even then when the Middle part of it is applied to either of the Poles: The Reason whereof is, because the Striate particles proceeding from the Load-stone, do find fitter Pores for them in the Iron, than in the Air, which is the reason why they go towards it. This likewise is the Cause why Needles endued with the Magnetick virtue, have the Poles of their virtue at their Ends or Extremities.

XXVIII.

And this
in a mo-
ment.

This Virtue is communicated, as it were, in a moment, the course of the Magnetick particles through the Iron being very swift; because they meet with, in the Iron and Magnet, Pores exactly fitted to their figure. Now this Virtue is afterwards confirmed by long stay; for the longer that the ends of the Branchy particles have continued turn'd one way, it is with the more difficulty that they are turn'd the contrary way. This Virtue is longer retain'd in the Load-stone, than in the Iron; because the parts of the Magnet are more stiff and inflexible, by reason of the Stony matter that is mixed with them.

XXIX.

Steel better
keeps the
Magnetical
Virtue, than
common
Iron.

Hence it is that Steel receives a greater Magnetick virtue than common Iron, forasmuch as it hath more and more open Pores, and doth more surely keep, and preserve the same; because its Branchy particles are more stiff and rigid.

XXX.

The Reason
why a
Load-stone
loseth no-
thing of
its Virtue.

The Reason why the Magnet, tho' it communicates its virtue to the Iron, yet loseth nothing of it, is, because nothing of its Substance or Constitution is destroy'd by this Contact, seeing this whole operation is performed by the Striate matter; which tho' it be hurried forceably and abundantly through the Pores of the Load-stone, yet by its passage takes nothing from the Magnet, nay, rather its virtue by this free communication thereof, is much increased.

XXXI.

By what
Efficiency
Glass and
Amber
draw to
them bits
of Straw
and Stub-
ble.

And here, seeing that besides the Load-stone there be some other things that draw to them outward Bodies, such as Glass, Amber, Jet, Diamonds, which attract bits of Straw and Stubble; it will not be amiss to say something of them. And first concerning Glass; it seems probable that besides those Intervals, which in other Bodies give a free passage to the Matter of the first Element,

there be some Long pores like unto slits, and so narrow, that they are only fit to admit the Matter of the first Element, without being capacious enough to receive the Globuli of the second Element. And forasmuch as the Matter of the first Element, accommodates it self, as hath been said, to the Pores through which it passeth, and assumes their figures, as it is wandering through those little Slits or Chinks, it becomes turned into certain Wreaths or Twists; which because of the various disposition of the parts of Air, being not able to penetrate its Pores, do remain in their own lodging, and there move from one Chink to another by a Circular motion. So that when a piece of Glass is rubb'd hard and swiftly against some other Body till it grow hot, the particles lodged in the Glass are by this agitation first thrust out of their places, and so being driven from the Glass, and flying through the Air, penetrate the Pores of other Bodies: But because they cannot so freely course it between their parts, they soon return to the Glass again, and carry along with them those small Bodies, out of whose Cavities they cannot extricate themselves. And the same may be said of Diamonds, Amber, Jet, Rosin, Sealing-Wax, and the like, since we suppose the same Intervals or Pores in them, viz. such as only can admit the Matter of the first Element, and that their Particles have the same force to enter the Pores of Bodies, and of carrying them along with them.

CHAP. XI.

Of Water.

WATER is a congested Mass of Particles of the Third Element, which are very thin. What Water is longish, smooth, and therefore very flexible, resembling small plying Cords, disposed to bend and yield every way.

That the Particles of Water are smooth, may easily appear by Bodies that are wetted therewith; The Particles of Water which with the least degree of Heat, or with the motion of the Air only are dried. For the Particles of Water are by this means separated, and by force of the Motion of Heat, or the Agitation of the Air, driven out from the Bodies to which they were joyned. Hence it is, that Water is not frozen without some difficulty; for its Particles being smooth, are readily separated from one another, by the Agitation of the Ethereal matter.

Now that these Watry particles are in continual motion, besides what we have already cleared in our General Physiology, may be proved by these Instances, viz. that Liquors pour'd together do readily mingle; that Oil and Water, by strong shaking, become incorporated together; that Colours and Tastes are, as it were, in an instant diffus'd through all the parts of them, and other such like, which occur to our daily Experience.

Forasmuch as the Subtil matter is in perpetual motion, and never ceaseth to agitate the Bodies, through which it passeth; it needs not seem strange to us, that it should make the Water Liquid, seeing it moves all its Particles one by one, and bends them one upon another. And on the contrary, when

is so
transparent.

X.
Why Water
is so
transparent.

when this its Force is hindred (which chiefly happens in *Winter* time, because of the *Sun's* distance) the parts of the *Water* being promiscuously huddled together, and without order heap'd upon one another, remain immovable, and constitute that which we call *Ice*. Which Consistence of the Parts, is the Reason why *Frozen Liquors* are so cold, for that their Parts being deprived of the agitation of the *Subtil matter* are closely joyned, and therefore cannot admit any greater particles of the said matter or heat.

V.
How *Water* becomes turn'd to *Ice*.

Water is never frozen, but when the *Heavenly matter* which runs betwixt the *Watry Particles*, becomes more subtil than is customary; by which means it comes to pass, that the *Pores* of the *Ice* being reduced to the measure of these lesser particles of that matter, do shut out those that are never so little bigger. For which Reason it is that *Ice* is extrem cold, and always keeps its Hardness, tho' it be kept till the midst of *Summer*. Neither doth it grow soft by little and little, as *Wax* doth, forasmuch as by reason of the narrowness of its pores, the heat cannot enter into the Inner parts of it, but as the Outward parts of it begin to melt.

VI.
Some parts of the *Water* are flexible, and others inflexible.

There are two sorts of particles in the *Water*, *Flexible* and *Inflexible*: The *Flexible* particles are those, which are agitated by the *Heavenly matter* that surrounds them; and of these, *Fresh-water* is composed. These *Flexible* particles have no *Elastic force*, and apply'd to the *Nerves* that are disperst through the *Tongue*, they produce no *Taste*; for wherever they meet with the least resistance they slip away. The *Inflexible* parts of the *Water* are stiff and sharp, like so many *Swords*, and these constitute *Salt*. As appears from what hath been said before.

VII.
Why *Salt water* pricks the *Tongue*.

Hence we may see the Reason, why *Salt-water* as it were pricks the *Tongue*; for since the *Saline particles* cannot be made to ply or bend, by the subtil Matter which surrounds them, they continue stiff, and as so many sharp-pointed *Needles* enter the pores of the *Tongue*, and entering, prick them with their Points: Whereas the parts of *Fresh-water* lye smooth upon the *Tongue*, and touch it not with their Points, but with their Sides.

VIII.
Salt-water is more heavy than *Fresh-water*, and lighter than *Earth*.

It also appears from what hath been said, why *Salt-water* is more heavy than *Fresh*, viz. because it abounds with thicker and more solid Parts, which therefore cannot be resolved into *Vapours*: For the *Saline particles* being long and strait, they cannot long continue suspended in the *Air*, but that one end of them must hang downwards, which is an obstacle to their mounting upwards. But *Water*, whether *Salt* or *Fresh*, is lighter than the *Earth*; because quantity for quantity, it hath less Force to withdraw it self from the Center of its motion, than the *Earth*.

IX.
Why *Water* is transparent.

Water is made *Transparent* by the *Globuli* of the second Element, which continually passing through the pores of it, and being of sufficient force to remove some of its particles, by this means easily form therein passages fitted for the transmission of *Light*. And as for those *Liquors* which are dark and troubled, the Reason thereof is, because their parts are too thick to admit the *Globuli* of the second Element. As is apparent in *Blood* and *Quicksilver*.

The Surface of the *Water* is kept smooth and even, by the motion of the *Air*, which continually presseth down its Outward parts; whence it is that small *Needles* being laid softly upon the Surface of it do not sink, but make a kind of hollow under them; but when once the surface of the *Water* is divided, they immediately sink to the bottom.

Tho' the *Water* do admit the *Light*, as well as the *Air*, as being capable of the Rectilineal persure of the Matter of the second Element, continually passing through its Pores; yet is it not so susceptible of Sounds as the *Air*, because its parts are thicker and more slowly moved. Hence it is that Vessels fill'd with *Air* being struck upon yield a Sound; but not those that are full of any *Liquor*. And for the same Reason, *dry Wood* is more susceptible of Sound, than *Green-wood*; because the pores of *Dry-wood* have the same respect to those of *Green-wood*, as an Empty Vessel hath to one that is full; the pores of the *Dry-wood* being open and empty, whereas the other are stop'd up.

It is a Question much canvas'd, whence the Saltness of the *Sea* proceeds? Which may be thus answer'd, That the same is caused by the *Salt*, which is mingled with its *Waters*: For *Sea-water* abounds with *Salt*, as appears by its distillation; for the *Water* distill'd from it is sweet, and the *Salt* remains in the bottom. What some say, that the *Sea* borrows its saltness from some *Veins* of *Salt*, doth not seem probable; because if those *Veins* be near the *Water*, they must needs have been all dissolved long before this; for *Salt* immediately dissolves in moisture. And if the waters do not touch them, how shall they communicate their saltness to them? We conclude therefore, that the *Sea* is salt, and continues so, because it abounds with many inflexible and stiff Parts; which tho' they may get up into the *Air* for some time, yet by reason of their Thickness, soon fall down thither again. Which is the Reason also, why they cannot, together with the flexible particles, pass through the *Sand*, but are left behind.

But tho' the *Sea* be salt, yet *Fresh-water* hath been sometimes found in the midst of it, and that by reason of the many subterraneous Channels of *Fresh-water*, which are found at the bottom of it. Thus we see, that the *Sea* about the shoars, which are near to the Mouths of great Rivers, is less salt; because the *Fresh-water* of the Rivers overpowering the *Salt-water*, continue to be fresh for some distance in the *Sea*. As may be seen at the Mouth of the River *Rhône* in France, where the *Salt-water* doth not mingle with its *Fresh-water*, till at some distance.

We are not to think with some Modern Philosophers, that *Water* is cold in its own Nature: For tho' it feels cold, when frozen, this only happens to it from the Rest of its parts, wherein the Nature of Cold consists. But when it is in its Liquid form, it is indifferent to Heat or Cold, as being naturally susceptible of a greater or less degree of Agitation, according to which it appears hot or cold. So that when heated *Water*, by degrees is reduc'd to its former coldness; this proceeds not from its Natural propension to Coldness, but because it communicates some part of its Agitation (wherein its heat doth consist) to some Neighbouring

X.
Why the Surface of the *Water* is smooth and even.

XI.
Why the *Water* is not so fit to receive Sounds, as the *Air*.

XII.
Whence the saltness of the *Sea* proceeds.

XIII.
The *Sea* being salt, how comes it to pass, that *Fresh-water* is found in it?

XIV.
Why *Water* is not naturally cold.

X. *houring Bodies.* And therefore when *Hot-water* is so close shut up in any *Vessel*, as to have no Communication with any ambient *Bodies*, it preserves its *heat* for a long while. *Running-water* therefore seems to be of such a Temperature, as to be a kind of Mean betwixt the Excess of *Heat* and *Cold*; seeing that by great *heat* it would all vanish into *Vapours*, and by excess of *cold* be lock'd up into *Ice*.

XV. *Hot Fountains do not receive their Heat from subterraneous Fires.* Supposing, according to what hath been deliver'd before, that the *Earth* contains great store of *Brimstone*, *Jews-Lime*, and other inflammable *Bodies*, it will not seem strange to us, that *Hot-waters* or *Bathes* break forth in several places of the *Earth*. Nor is it necessary that these *Bodies* should be actually set on fire, in order to heat the water flowing by them: For it doth not seem probable, that any such matter should be able to flame in the *Earth*; because the Smoak of it would soon choak it for want of vent, or the surface of the *Earth* must burst to give it *Air*. Wherefore it seems more likely, that as of *Saltpeter*, *Brimstone*, *Jews-Lime*, and *Quick-Lime* Mixtures are made, which by sprinkling water upon them, do grow hot (which happens also to *Aqua Fortis* and Oil of *Tartar*, and to *Butter of Antimony*, and *Spirit of Nitre*, when put together;) so the like Mixtures may be under the *Earth*, and the same Heat may happen when any Moisture comes to them.

XVI. *But from a Mixture of Heterogeneous Bodies.* For it is not always necessary that *Hot Fountains* should proceed from *subterraneous Fires*, seeing that a mixture of *Heterogeneous Bodies* is sufficient for this purpose, as being able by Fermentation to produce the same effect. Heat therefore is communicated to *Hot Bathes*, whilst their water passeth through Channels heated by the fumes from *Jews-Lime*, *Brimstone*, or the like. For the water, by passing through these *Hot places*, becomes heated thereby, after the same manner as when water is heated in a *Stove*.

XVII. *The Qualities of Water.* Accordingly, if the water of *Fountains*, before it breaks forth on the surface of the *Earth*, happen to pass through *Juices* and *Minerals*, it acquires from them their *Taste* and *Smell*, and several other qualities. For the strong Scents of some waters are from *Brimstone* and *Jews-Lime*, their Bitterness, from *Nitre*; their Acidity from *Copperas*; their Harshness and Adstringency, from *Alom*; their Saltiness, from *Common Salt*; their sharp Taste, from *Marchasite* or *Fire-stone*; their Iron taste, from *Iron*.

XVIII. *Waters receive their Medicinal virtue from the Mineral Juices, through which they flow.* And forasmuch as those *Juices* through which these waters flow, abound with a *Medicinal virtue*, 'tis from them that they derive it, and by means thereof are profitable for the Cure of many *Diseases*. The *Purgative virtue* that some have being chiefly owing to *Brimstone*, *Salt*, or *Nitre*; the *Adstringing faculty* of others to *Alom*, which is made use of by *Physicians* against *Ulcers*, *Bloody-fluxes*, and *Relaxations* of the *Nerves*. Those *Waters* that have a power of mollifying the *Earth*, receive it mostly from *Brimstone* and *Jews-Lime*. Which is the Cause why *Bituminous Bathes* are accounted profitable to those who are troubled with the *Gout* or *Ach* in their *Hips*. In like manner *Waters* are made hurtful, by being imbued from some *Metallick Bodies*; such are those which have received a taint from *Lead*, or *Quicksilver*,

or are infected with a petrifying *Juice*, or of some middle *Mineral*, as that of *Antimony*; and therefore causing *Vomitings*, and *Scourings*. And, in a word, whatsoever *Waters* exert any special Operation on the *Body of Man*, have it derived from *Subterraneous matters*.

CHAP. XII.

Of the Ebbing and Flowing of the Sea.

I. *The Ebbing and Flowing of the Sea is proportion'd in time, according to the Motion of the Moon.* BY the *Sea-Tide* we understand the *Ebbing* and *Flowing* of the *Sea*, which twice happens in the time of 24 hours, and about 50 minutes. The *Sea-Tide* is *Regular*, tho' it do not happen at the same time, nor after the same manner in all places. For the *Sea* swells as oft as the *Moon* passeth our *Meridian*, whether above or under our *Horizon*; and it falls again, when the *Moon* is on the *Horizon*, whether it riseth or sets: For we find, that the *Sea* in its motion keeps a proportion of Time with the *Moon*; for as the *Moon* riseth every day 3 Quarters of an Hour and 5 Minutes later, so at the same Interval doth the *Sea* rise.

II. *What the Sea-Tide is.* For the *Flowing* of the *Sea* is nothing else, but the motion of the *Sea-water* towards the *Shoars*, in about Six Hours time: And the *Ebbing*, is the motion of the said *Waters* from the *Shoars*, *Seaward*, in other Six Hours time.

III. *The Tide is not the same in all Seas.* The *Tide* is not the same in all *Seas*; but in some the same is greater, and in others less, yea, in some the *Tide* is very inconsiderable, or none at all. In some places the *Flowing* of the *Sea*, is equal to its *Ebbing*, in others greater and in others less. The greatest variety of *Tides* is at the *Equinoxes* and *Solstices*, as also at the different Aspects of the *Moon*: Thus at the *Full* and *New Moon* the *Tide* runs highest, as it is least at the *Quarters*. This is observ'd in almost all the *Shoars* of *Europe*, which the *Ocean* beats upon. But the *Flood* is always so much the greater, and comes the slower, by how much the *Shoars* against which they beat, lye more towards the *North*; and on the contrary is scarcely sensible between the *Tropicks*.

IV. *The Opinion of the Ancients, and some of the Peripateticks, concerning the Cause of the Sea-Tide.* The *Ancients*, to give a Reason of all these *Appearances*, feigned the *World* to be a great *Animal*, which by breathing through its *Nostrils*, placed by them at the bottom of the *Sea*, did cause the *Sea* to rise and fall. But this *Monster* is long since vanish'd into a *Chymera*. Some of the later *Philosophers*, *Peripateticks*, and others say, that this *Reciprocation* of the *Sea* proceeds from an *Occult quality*. But what is this else, but a *Profession* of their *Ignorance*, and that in plain terms they do not know the Thing they pretend to *Explicate*? At this rate, it is an easie matter to explain all the *Mysteries* of *Nature*. For that which is hid is not known; and indeed we know no Effects, but such as we can demonstrate by their proper *Causes*.

V. *The Opinion of Galilæus, and of some others.* Some attribute this Effect to the *Agitation* of the *Saline particles* of the *Sea-water*, by the moderate heat of the *Moon*. *GALILÆUS*, to the multifarious and unequal motion of the *Earth*. But these their *Opinions* are overthrown by this *Observation*, that neither of them gives the least probable Reason of these motions in the upper *Hemi*.

Hemisphere, when the *Moon* is in the lower; and on the contrary. The latter *Opinion* is indeed the better of the two, but somewhat obscure, and not altogether consonant to *Reason*; because it attributes less to the *Moon* than her due, who certainly hath a great stroke in this matter.

VI. For the understanding of the true Cause of the *Sea-Tide*, some things are to be presupposed.

First, That the *Course* of the *Moon*, and of the rest of the *Planets* is *Elliptical*, not perfectly Round. And this is granted by all who suppose the *Heavens* to be fluid.

Secondly, That whilst the *Earth* is whirl'd about from *West* to *East*, in the *Center* of her *Vortex* A B C D, the *Moon* is carried in the outward *Surface* or *Circumference* of the said *Vortex*, and in a *Months* Space absolves her *Course*.

Thirdly, That when the *Moon* is plac'd at B, the *Heavenly* matter will be more strong between B, and 6, than between 8 and D; because it there flows through a narrower Space, by reason of the *Moons* presence; and therefore the place of the *Earth*, which is determin'd by the force of the *Circumfluent* matter, will also be changed, that is, the *Earth* will withdraw towards D, till the force be equal on both Sides.

These things presuppos'd, let us consider the *Figure* where the *Elliptick* A B C D represents the *Vortex* of the *Earth*, in the midst whereof the *Earth* E F G H is placed. The *Circle* B C, the *Globe* of the *Moon*; 1 2 3 4, the *surface* of the *Sea*; and 5 6 7 8, the *Air*, which surrounds the *Sea*. This suppos'd, we may easily understand that the *Rising* and *Falling* of the *Sea* must proceed from the presence of the *Moon*. For seeing that all places are fill'd with *Bodies*, and that the same portion of *Matter* is preserv'd every where; it follows that *New Bodies* cannot be admitted into them, except thereby other *Bodies* be compressed, so that they that come in must thrust the others out of their places, and force them to betake themselves elsewhere. Which happens here by reason of the *Lunar Globe* B C; for the *Moon* being a great *Body*, and requiring a large Space to dilate it self in, she cannot ascend upon our *Horizon*, without lessening the *Interval* that is betwixt her and the *surface* of the *Earth*; and by this means forcing the *Celestial* matter to flow more swiftly; and consequently pressing as well the *surface* of the *Air* 5 6 7 8, as that of the *Water* 1 2 3 4 the more, which being fluid *Bodies*, do readily yield to the said pressure.

It is of no weight, to say that the *Air* and *Heavenly* matter move more slowly in the great *Diameter*, even then when the *Moon* takes up a part of it, than they move in the little *Diameter*, when the *Moon* is without the same: For it is enough, if the passage only of the *Air* and *Celestial* matter be more straitned in the great *Diameter*; when the *Moon* is in it, than it is when she is not; to cause the *Waters* that are in this *Diameter* to be driven towards the *Poles*, and so by this means to cause an *Ebbing* and *Flowing*.

IX. Forasmuch therefore as it is manifest, that the *Earth* E F G H is kept in, and determin'd to the same place, by the equal pressure of the *subtil* Matter that surrounds it; it cannot be conceived, how that part of the *surface* of the *Earth*, which is opposite to the *Moon*, existing in the Point B,

should be more pressed, without conceiving at the same time, that the *Matter* of the *Heaven* must push the *Earth* out of its place, thrusting it forwards to the opposite part D, until the *Earth*, about the Point 8, be pressed after the same manner, as about 6. Wherefore there are two *streights*, B and 6, and D and 8, made in this *Vortex* or *Heaven*, which are diametrically opposite to each other, viz. the one betwixt the *Moon* C, and the *Earth* T; and the other between the *Earth* T, and D.

Whilst therefore the *Celestial* matter, which moves round about the *Earth*, moves more swiftly in these *Streights*, one whereof is betwixt the *Earth* T, and the *Moon* B; and the other betwixt the same *Earth* T, and the opposite part D. It presses the *Sea* 2 and 4, and drives it from thence towards those places that are free from this *Pression*, that is, towards G and E; where swelling by the force of its own *Heaviness*, it is driven towards the *Shoars*.

And because the *Circumvolution* of the *Earth* about its own *Center*, is performed in 24 *Hours*, if we divide its *surface* into Four parts E F G H, that part of it which is at F, where the *Sea* is lowest, because of the presence of the *Moons* *Body*, 6 *Hours* hence will be in G, over against the Point C, where it is highest; and after 6 *Hours* more at H, and so on. Whence it follows, that the *Sea-water* must of necessity flow and ebb every 12 *Hours*, in one and the same place. And because the *Moon* every *Day* runs 12 *Degrees* towards the *East*, the *Tide* must be retarded, that is, come later by almost an *Hour*: For tho' the *Earth* be carried about in 4 *Hours*, and must at a certain time bring back the same part of the *Ocean*; yet because it must also run over those 12 *Degrees*, which the *Moon* hath run through before it can bring back that part of the *Ocean*, and oppose the same to the *Body* of the *Moon*, so it is that the *Tide* happens every day about 50 minutes later; and consequently between the two *Tides* that happen every day, there is the difference of 25 minutes.

It is easie to apprehend, that if the *Earth* and *Moon* were immovable, the *Waters* that have been prest towards the *Poles*, would not return from thence; forasmuch as they would be held there by the same Cause that hath push'd them thither: But seeing that the *Earth* and the *Moon* are in a perpetual motion, it will follow of necessity, that the *Waters* which have been thrust from the *Parallel* which is under the *Moon* towards the *Poles*, must return afterwards by their own weight, from the *Poles* towards the *Parallel*, above which the *Moon* is, at that time when the parts, from whence they have been driven, are no longer opposite to the *Moon*.

It is apparent also, why the *Tide* must come later to the *Northern Shoars*, than to those that are further from the *North*; for seeing that the moved *Waters* are driven from the *South* part, to the *North*, they must of necessity reach the nearer *Shoars* before those that are further off: And because the *Waters* that beat the *Shoars* near to the *Torrid Zone*, may pass further and flow toward the *Poles*, except they be hindered by the *Northern Coasts*, it comes to pass by this means, that the *Tide* is greater and more sensible in that part which is at a greater distance from the *Equinoctial Line*; because the *Waters* about the *Equator*,

two several parts.

X. How the Flowing of the Sea is caused.

XI. The Sea-Tide must happen twice in a day.

XII. Why the Waters return to the Parallel, above which the Moon moves.

XIII. Why the Tide is longer in coming to the Northern parts, and therefore greater there.

quator, by reason of the largeness of the Circle, are diffused towards the Poles, that they may be gather'd together in a narrower Region.

XIV.
An Obje-
ction an-
swer'd.

But if any one Object here, That the Waters, in the space of 6 Hours, which is the time of the Duration of the flood, cannot flow from the Tropick to the Poles; and thence conclude, that the swelling of the Sea towards the Northern parts, cannot be an effect of the pressing of the Moon betwixt the Tropicks. I answer, That in order to make the Sea swell towards the North, it is not necessary that the Waters, betwixt the Tropicks, should go to the Poles; but that it is sufficient, if they only drive away those that are nearest; and that these again drive others before them, and so on to the last; which may be done in less than 6 Hours time, because the Sea is a continuous Body.

XV.
Why the
greatest
Tides are
about the
Equinoxes.

Now the Body of the Moon continuing of the same Thickness, takes up more of the narrow Space, when she is in the less Diameter, than she does of the larger Space, when she is in the greater Diameter; and therefore it matters not whether she be in her farthest distance from the Earth, or in her nearest; because at either time she makes the Space of the Vortex wherein she is straighter or more narrow; and it is only her presence over against the Earth that is the Cause of the Tide, and not her nearness to it. And this furnisheth us with the true Reason, why the highest Tides are at the Equinoxes; because at the Beginnings of Aries and Libra, the Moon more directly acts upon the Earth, and presseth it accordingly, forasmuch as its Plain at both those times doth not decline from the Plain of the Equator of the Earth, above 5 Degrees. For then the middlemost part of the Earth, or the Equator, is in the Ecliptick, near to which the Moon always continues; and consequently the Space being there narrower, the pressure must be so much the greater. But at the time of the Solstices, she declines 23 Degrees and 30 Minutes from the Plain of the Earths Equator. Seeing therefore that from the former direct Opposition, doth follow a great Pressure of the Air and Water, it is no wonder if about that time the greatest Tides do happen.

XVI.
Why the
Tides are
greater at
New and
Full Moon,
than at
the Quar-
ters.

So likewise it is manifest, why the Tides at New and Full Moon are greater, than at the Quarters. For the Vortex ABCD, wherein the Moon is, is not exactly round, but somewhat Elliptical, and leaves a greater Space betwixt the Earth and its Circumference, about A, and C, than about B, and D. And therefore seeing the Diameter, wherein the Moon is when she is New or Full, is narrower than that which intersects it at right Angles, it must follow, that when the Moon is in those narrower freights of Heaven, she must with more force press the interfluent Matter, and consequently produce greater Tides. But in the Quarter of the Moon about A and C, the Tides are less; because the Moon is then in those more ample Spaces, and consequently there must be a less pressure of the Waters.

XVII.
An Obje-
ction an-
swer'd.

It signifies nothing therefore to say, that the Moon is not always nearer to the Earth, when she is in Conjunction or Opposition, than when she is in her Quarters; and that consequently the Tides ought not to be greater at the Conjunctions or Oppositions, than at the Quarters: Because, as I have before observed, the highest Tides do not precisely depend upon

the Moons being nearer to the Earth; but because at the Conjunctions and Oppositions the Moon is always in the least Diameter of the Ellipsis; where, whensoever she is, be she nearer to, or further from the Earth, she always more straightens the passage of the Air and Heavenly matter, than she doth when she is in the greatest Diameter of the Ellipsis.

The greatest Floods commonly happen 3 days after the New and Full Moons, because of the Disposition the Sea-water is in at that time, to be moved more than ordinary: For having been strongly moved the two foregoing days, it is no wonder to find the Tides still to increase for 2 days after that the Sea hath received its greatest Impulsion from the Moon.

XVIII.
Why the
greatest
Tides are
three days
after the
New and
Full Moon.

It remains still to be explained, how it comes to pass, that seeing the Moon is the common Cause of all Tides, there is a great variety of them to be observed in the Ocean. To clear this Difficulty, I say, that this variety of Tides is often to be attributed to the Sea-shoars, which according as they are nearer or more remote, so the Waters reach them sooner or later. Wherefore, if the Sea about the Aquitain shoar flows 7 Hours, and ebbs but 5; and on the contrary, if near Canada, it flows 5 Hours, and ebbs 7; if on the shoars of Guinea in Africa, it flows 4 Hours, and ebbs 8. If at Venice the Tide rises many Foot high, and at Ancona nothing at all, or very little, this depends on the diversity of the situation of those Coasts. Of this we have an Instance in the Banks of Rivers, between which, according to the difference of their situation, the Water runs either headlong, or glides away smoothly; runs winding and turning, or takes a strait course. The Aquitain Sea therefore is longer a flowing, than it is ebbing; whereas on the Belgick shoar, the Flood and Ebb is equal, because of the different degrees of their Steepness and Declining. So likewise at Venice, and on the Coast of Syria, the Tide riseth much higher than with us; because the former places are situate, as it were, at the end of the Channel; whereas the latter are in the midst of it: For it is manifest, that the rising or falling of the Water shaken in a Vessel, is only perceived at the Extream parts of the Vessel; whereas in the Middle there is nothing to be perceived, but an equal and simple flowing of the Water.

XIX.
The Cause
of the
various
Tides in
the Sea,
proceeds
from the
different
situation
of the
several
places,

But to determine something more particularly about this Diversity of Tides, we are to take notice, that the motion of the Waters chiefly depends on this, That in that vast Tract of the Sea, there be some peculiar places where the Waters are very much pressed, because of the Moons presence; and others again, where no force at all seems to be put upon them: Which makes that the Waters are driven to those places where there is no pressure, and so arise there against the Shoars, and make a Flood. Wherefore, if there be any Waters in the Sea, which because of the inconsiderableness of their Extension, are all over cover'd by the Body of the Moon, they must needs be so equally press'd in all their parts, as that no Rising or Falling can be perceived in them. Thus those Lakes, Pools, and Rivers that are between the Tropicks, have no Tides, seeing that because of the smallness of their surface, compar'd with the Bulk of the Moon, they cannot be sensibly press'd one way more than another.

the vari-
ous pres-
sion of
the
the Moon.

Wherefore

To the Honorable the Secretary of the War
in the County of ...
The Plate is humbly
Presented by ...

Book. 1. Part. 6. Chap. 13.

G. Freeman. Sculp.

J. Kip. Sculp.

To Captaine Thomas Newman of Iwer
in the County of Buckingham Gent.

This Plate is humbly Dedicated by Ric: Blome

XXI.
Why some
Seas suffer
no Tides.

Wherefore it is no wonder, if in the *Baltick Sea*, the *Dead Sea*, and the *Euxine Sea*, no *Tides* at all are perceived; because those *Seas* have no intercourse with the *Ocean*; or if any of them have any communication with it, it is by such narrow passages, that the agitation of the *Sea* can have no great force upon them.

XXII.
The meeting
of Waters,
a Cause of
the difference
of Tides.

To this Diversity of *Tides*, the various Meetings of *Waters*, and difference of *Winds*, which differently agitate them, and drive them one against another, do much contribute. For the *Sea* flows continually from *East* to *West*, which those who sail from *Spain* to the *West Indies* have Experience of; for they frequently perform this *Voyage* in 30 *Days*; whereas in their Return, they spend no less than 3 *Months*, because the *Course* of the *Sea* is against them, and runs *Westward*. And the same is observ'd by those who sail from *Lisbon* to *Brazile*.

XXIII.
Why the
Gulf of
Venice
flows to-
wards the
West.

If you Object, That the quite contrary to this is found in the *Gulf of Venice*; for the *Sailers* tell us, that when they are over against *Epirus* and *Dalmatia*, they perceive that the *Waters* are carried with a strong Stream *Westward*, towards *Venice*; and that when they are near the Coast of *Italy*, they are carried *Eastward*, towards the *Morea*. I Answer, That these motions of the *Waters* are caused by *Rivers*, which from subterraneous Cavities flow into the *Sea*; which in their coming forth, do with great Violence push forwards the water of the *Sea* that meets them, and divert it from its *Course*. Or else those *Rivers*, being beaten back by the *Water* of the *Sea*, are forc'd to turn their motion, and to run another way.

XXIV.
An Obje-
ction
against the
foregoing
Explica-
tion, of the
Ebbing and
Flowing
of the Sea.

But against this Explication of the *Ebbing* and *Flowing* of the *Sea*, it is Objected, First, That if the *Moon* did drive the *Waters* from between the *Tropicks* towards the *Poles*, it would follow, that when the *Moon* is in the *Meridian*, it would be *Low-water* in that part which was opposite to it, and *High-water* towards the *Poles*; whereas Experience shews the contrary, viz. that the *Tide* comes in when the *Moon* approacheth to the *Meridian*, and that the water falls, as she withdraws from it.

XXV.
Answer'd.

I Answer, That when the *Moon* is in the *Meridian*, the *Sea* must be low precisely in that place which is over against it; but it doth not follow therefore, that it must be *High-water* under the *Poles*, but only that it must be *High-water* between the *Tropicks* and the *Poles*, and so it is. For we find by Experience, that the *Sea* increaseth from about the *Tropicks*, to the most Northern part of *England*; and that from thence, towards the *Poles*, it increaseth no more. Whence it is, that in the Northern *Ocean*, from about the *Latitude* of about 65 *Degrees*, to the *Poles*, there is no *Flood* nor *Ebb* at all.

XXVI.
A second
Objection
against
this Expi-
cation of
the Tide.

In the Second place it is Objected, That the *Celestial matter* which follows the *Moon*, and which moves somewhat swifter than she doth, from *West* to *East*, doth not only run under the *Moon*, but also above it, and on the sides of it; so that that part of the *Sea*, over against which the *Moon* is, will be no more pressed than the rest.

XXVII.
Answer'd.

For Answer: It is certain that the *Heavealy matter* which follows the *Moon*, and is in a ten-

dency to go somewhat swifter than she doth, from *West* to *East*, doth not all of it flow under the *Moon*, but that a part of it passeth above it, and on the sides of it; yet doth not this hinder, but that the Way of the said matter under the *Moon* is more freightned, which is sufficient to make the *Sea* to be more pressed in that part, than in all the rest.

From what hath been said, we may gather, that there is a *Threefold Tide*, according to the difference of Times, viz. a *Daily*, *Monthly*, and *Yearly Tide*.

The *Daily Tide* is that, whereby the *Sea* in 24 *Hours* time doth twice approach to the same *Shoar*, and as many times retires again in this order, That the *Tide* of the *Day* following falls about 50 minutes later, than that of the *Day* foregoing.

The *Monthly Tide* consists in this, that the *Daily Tide* increaseth twice in a *Month*, viz. about the *New* and *Full Moon*, and twice decreaseth, viz. in the *Quadrant Aspects* of the *Moon*.

The *Yearly Tide* consists in this, that the *Monthly Tide* twice in a *Year* riseth higher than ordinary, viz. at both the *Equinoxes*, and as often decreaseth, viz. at the *Solstices*. Wherefore if these 3 *Periods* be compared with the *Daily* and *Yearly motion* of the *Earth*, it will seem impossible, they are the words of *GALILEUS*, in the 4th *Dialog. System. Mundani*, That *Naturally* there should be any *Tide*, supposing the *Earth* to stand immovable, without betaking ones self to the absolute Power of *GOD*, and conclude, that the *Sea-Tide* is a *supernatural Effect*.

XXVIII.
There is a
threefold
Tide.

CHAP. XIII.

Of the Air.

THE AIR, according to the Order of Nature, follows the *Earth* and *Water*, to the Surfaces whereof it adheres and is joyned. The *Astronomers* call that part of *Heaven*, *Air*, into which the *Vapours* and *Exhalations* ascend. And because all those *Exhalations*, which are continually breath'd forth from the *Earth* and *Sea*, are by the pressing of the *Subtil matter*, dispos'd into a Round surface (at least as far as the agitation of those *Bodies* will permit) they gave the Name of *Atmosphere* to those *Vapours*. It is various, according to the diversity of *Heat* and *Cold*, and of the *Vapours* themselves; and from thence proceeds a various *Refraction* and *Reflexion* of the *Rays* of the *Sun* and *Moon*, and the other *Stars* in the *Air*.

Accordingly we are to distinguish a twofold Substance in the *Air*, viz. one *Native* and *Primitive*, which hath been from the Beginning of the *World*, and which is the most pure and thin part of it: And the other *Adventitious* or *Foreign*, which consists of the *Effluvia* or *Steams* of other *Bodies*, according to the difference of *Place* and *Time*. Hence the *Air* is accounted, First, absolutely Pure, when these *Steams* are not so thick, that they can easily cling together, and thereby lose the form of *Air*. Secondly, With respect to us, whilst those *steams* are not so hurtful to our *Bodies*; such as they are at the time of *Epidemical* and *Contagious Diseases*.

I.
Of the
Atmosphere.

II.
There is a
twofold
Substance
in the Air.

The

III.
What the
Air is.

The Air is a loose Body, fluid and transparent, whose Particles are so small, and so little clinging together, that they may with the least force be separated from the Globuli of the second Element, and by a peculiar motion be carried independently about their own Center. The Fluidity of the Air proceeds, from its being compos'd of very subtil and thin Particles; for tho' their irregular Figures seem to dispose them to cling together, yet are they forced to continue separate, because the minuteness of their Branches makes them yield to the motion of the Subtil matter, which by its great Mobility keeps them disunited, and makes them continue in a Liquid form. And forasmuch as its Particles are thin and disjoyned, every one of them moves independently from any of its Neighbours, and takes up that whole little Sphere, which is needful to its being whirl'd about its own Axis, keeping all other particles out of it.

IV.
The Property of the Air is to Polish and Smooth.

The Air's Property is to polish and smooth moist Bodies, and to keep them from being easily penetrated; as appears in the Water, which easily bears a Steel Needle, or a Pane of Glass, as long as its surface is not broken. Now the Cause of this is, because the Parts of the Air are moved otherways than the Parts of the Water; so that by their rubbing against one another, both their surfaces are hardned, and made more unfit to be divided.

V.
What Vapours and Exhalations are.

But because the more subtil parts of Exhalations do compose the Air, it will not a little conduce to our better understanding of the Nature of the Air, if we explain what Exhalations are, and how they are distinguish'd from Vapours. Vapours therefore are nothing else, but Particles of Water, which the Heat of the Sun, and the Circular motion of the Earth, have separated from one another, and raised into the Air. And, Exhalations are certain Particles, which by the same Causes have been separated and raised from Earthly Bodies.

VI.
How they are said to be raised by the Sun.

When it is said, that Vapours and Exhalations are raised into the Air by the Sun, it is not so to be understood, as if the Sun did attract them by his Beams (for such an Attraction is unintelligible) but only that at the presence of the Sun, or some other Cause, the Subtil matter which pierceth the Pores of Bodies, doth separate some Particles from them; which finding no other place but the Air, wherein they can move, do tend that way, in a manner not much unlike to that, whereby the Dust, which in Summer time we tread upon with our Feet, mounts upwards, and is raised up into many Clouds, according to the number of those that Tread it.

VII.
Another Property of the Air, is to be Rarefied and Condensed.

The Air, and all Vapours, are easily condensed and rarefied, according as they are more or less agitated. They become Rarefied, when they are more swiftly than ordinary tossed by the Heat: For seeing their Particles are flexible, the least commotion doth dilate them, and then they require a greater Space to continue their motion in. Again, they become Condensed, when they cease to be agitated by Heat; for then their Particles cling together, and are compressed by Cold: For nothing else can be understood by Heat, but the Agitation of the minute Particles of Bodies; as by Cold, the Diminution or Cessation of that motion.

VIII.
The Air being com-

pressed, hath a power of springing back (which is

called its *Elastick virtue*;) and of extending it self into a larger space. By which means Instruments are made, which, with the help of the Air only, drive the Water upwards; as we see in Artificial Fountains; and others, that shoot Darts, like Bows. The Cause whereof is, for that when the Air is thus compressed, each of its spherical Particles hath not sufficient place left it, wherein to perform its Circular motion, by reason of the crowding in of other Bodies: And forasmuch as at the same time, the agitation of these Particles is continued, by the motion of the Heavenly matter perpetually flowing about those parts, it can be no otherwise, but they must hit against one another, and push each other out of their places; and thus at last, all of them together, make a strong push for it, to acquire a larger space.

Condensed Air is more heavy, than that which is Rarefied; because it contains less Heavenly matter. We may Experience this, by filling a Bladder first with a little, and rarefied Air; and afterwards with much, and condensed Air.

IX.
Air condensed, is more heavy than that which is rarefied.

From the Greater or Lesser Agitation, or Rarefaction and Condensation of the Air, we conclude, that the Compass of the Air is greater in Summer than in Winter; and therefore that what is commonly said, that the furthest distance of the Air from the Earth is of 52 Italian miles, is vain and uncertain. And the same is to be said concerning the three Regions of the Air, and their several Bounds; as when they ascribe to the Lowest Region, the height of half an Italian mile; to the Middlemost, of three and an half; and to the Highest, the height of 48 miles. For seeing there are no certain Bounds whereby these Regions are discriminated, it is a Fond undertaking, to go about to determine their Limits.

X.
The Distance of the Air from the Earth, is uncertain.

Another Property of the Air is *Heaviness*. For as we find that the Water presseth the bottom it lies upon; so likewise the Air, which encompasseth the Earth, doth press it on every side; and so much the more vehemently presseth it, by how much it is nearer to the Earth: As appears in a Bag-Pipe or Bladder fill'd with Air, which thereby becomes heavier than it was before. The same also may be proved, by the running of Quicksilver out of a Pipe that is stop't at the Top; for the Quicksilver changeth its height, according as it is carried along a low, or high place; so as to be depressed deeper in a high place, and mount up higher in a low place.

XI.
The Air is Heavy.

If you demand, How comes it then to pass, that we are not sensible of the weight of the Air? I answer, That the Reason is, because there is as great a Force in our Body to resist, as there is in the Heavy Air to press. For our Body being full of Blood and Spirits, doth with no less Force resist the pressure of the surrounding Air; which is the Reason, why the Air with its weight cannot move our Nerves, nor impress a sense of Heaviness upon us.

XII.
Why the weight of the Air is not felt.

Now the Heaviness of the Air, is to be ascribed to the watry Particles that are mingled with it; because that part of it which is diffus'd about the Earth, and reacheth to some certain distance, doth approach to the Nature of a watry Vapour, especially when many Steams are mix'd with it. Yea, if we may believe some Men, Thick Air is not only

XIII.
Whence the Heaviness of the Air proceeds.

only fill'd with *Stearns* from the *Earth* and *Water*; but receives also the *Breathings* of all other *Bodies*, and abounds with their *Spirits*.

XIV.

Why the Lower Region of the Air is hotter than the higher.

The *Region* of the *Air*, which is nearest to the *Earth*, is hotter than that which is at a good distance from it; because the *Solar Rays* being more copiously reflected from the compact *Body* of the *Earth*, do produce a greater agitation of its *Particles*. And therefore it is that the higher *Region* of the *Air* is cold, where *Clouds*, *Snow* and *Rain* are generated; because the *Rays* that are reflected from the *Earth*, do not so copiously mount up to it.

XV.

The Air is not Moist, as the Peripateticks suppose.

The *Peripateticks* hold the *Air* to be *Moist*, but without any sufficient ground, that ever I could understand; save only, because they thought it convenient to attribute two of their invented *Qualities* to the *Air*, which they call an *Element*. For tho' the *Air* be sometime called *Moist*, this doth not suppose it to have an *Essential Humidity*; but is so denominated, because of those *Watry particles* resolv'd into *Vapours*, that are joyn'd with it; which, when they are removed, it is called *Dry*. In which condition it cannot be turn'd into *Water*, no not by the most extream *Cold*.

CHAP. XIV.

Of the Elastick or Spring-like Force of the Air.

I. What a Spring is.

BY the word *SPRING* is commonly understood, that whereby a thing that is forceably bent and reduc'd to a less Extension, doth explicate it self again, and strive to return to its former Expansion.

II.

Wherein the Elastick or Spring-like force of Bodies doth consist.

This *Elastick*, or *Spring-like Force* in *Bodies*, proceeds from the *Subtil* or *Ethereal matter*; for when any *hard Body*, by Example, the *Blade* of a *Sword* is bent, its parts are by this means deflected from the *Convex* or *Jetting-side* of the *Blade*, and approach nearer on the *Concave* or *Hollow-side* of it; by which means the *Pores* on this side, must needs be made more narrow. Now because the *Subtil Matter* cannot exert its Force, to return through those parts of the bended *Body*, it passeth through; but strives at the same time, to reduce the parts thereof to that state wherein they were before, it must necessarily follow, that this *Body* must fly back.

III.

The Air is easily Condensed and Rarefied.

This Affection is most peculiar to the *Air*; which being nothing else, but a company of thin *Particles* of the third *Element*, which comply with the motions of the *Heavenly matter*, becomes easily condens'd; not only when by the decrease of *Heat*, and the less agitation of its parts, they do not with so great Force push against one another, as before they did; but also because they are shut up within the parts of another *Body*, which compress them more than ordinary. And on the contrary, the *Air* is as easily *Rarefied*, as soon as those *Causes* are removed, which reduc'd it to a less Space. Whether this happens by means of *Heat* let into its *Pores*, if before it was condens'd by *Cold*; or by opening the *Prison* wherein it was shut up before, if by *Compression* only it was reduced to a less Bulk.

For the *Air* can be dilated three several ways, either by its *Elastick virtue*, whereby it resists its being *Comprest*; or by the *Force* wherewith the *Subtil matter* strives to enter again into the *Pores*, whence it hath been driven away; or, lastly, by the extream *Agitation* of the said *Matter*, which moving the parts of the *Air* more strongly than ordinary, causeth it to extend it self farther. And on the contrary, the *Air* becomes condens'd, either because it is pressed; or, because the *Subtil matter*, which before moved its *Particles*, is slip away from them; or, because the said *matter* having lost part of its *Agitation*, hath no more the Force to move them as much as it did before, which makes them to lye more close together.

But we are to take notice, that this *Dilatation*, whereby the *Air* removes all *Obstacles* that compress it, is and must be very sudden; because its parts, which before could not move without clinging together, do then with joyn't Forces leap back, and by the force of the *Heavenly Globuli*, continually flowing about them, make an assault together, in order to take up a larger Space. There are various Experiments that are founded on this Affection of the *Air*, which we admire in *Artificial Fountains*, and *Wind Guns*, which shoot *Leaden-bullets*, and other things.

For let the *Air* be compress'd in the *Pneumatick Vessel*, the lower part of it being fill'd with *Water*, and the *Water* will spout out thence with so great force, that it will surpass almost any supposed height. For Example, Let the *Pneumatick Vessel* be *A B C*, the lower part whereof *B C* contains *Water*, and the superiour *B A C* *Air*; which being crowded into it by the *Pipe A D*, at several times; let it be compress'd, as is wont, in the upper *Cavity B A C*; then let the *Tube* or *Pipe A D* be well stop'd, by turning the *Key* of the *side Pipe*, appearing above *B*. This supposed, if the *Key* of the greater *Pipe D A* be open'd, the *Water* will spout forth through the said *Pipe* with great force to *E*, being forc'd upwards by the compress'd and condens'd *Air*. And forasmuch as the *Air* is still capable of greater degrees of *Compression*, it is certain that the *Air* may also be push'd upwards with still greater and greater force.

The Reason of this Experiment is this, that the *Particles* of *Air* contained in the *Pneumatick Vessel*, being thin, and separate from each other, do yield to the motions of the *Globuli* of the second *Element*; But when these *Globuli* are by some force thrust out, the *Particles* of the *Air* are forc'd to come nearer together, and entangle one another, so as that they can no longer whirl round, as they were us'd to do. Now being told about by the *Subtil matter*, they with their *Corners* hit one against another, and thrust each other out of their place: By which means they so bend their Force, to get more room for themselves, as that by that Effort they spout out the *Water* with great force towards *E*.

And for the same Reason a strong *Wind* can be excited, by means of the *Compression* of the *Air*, which will be able to express all Variety of *Sounds*. For so we Experience, that even great *Organs*, by the *Pneumatick Art*, can play variety of *Tunes*, without any assistance of a *Musicians Hand*, to wit, by our blowing into some *Pipes*, and thereby turning a *Wheel*, whose

IV.

The Air can be Rarefied and Condensed divers ways.

V.

The Action whereby the Air flies back like a Spring, is very sudden.

VI.

An Example of an Artificial Fountain.

Figure 47.

VII.

Musical Wind-Instruments may be play'd upon by the Compression of the Air.

Teeth shall tuneably strike the Keys of the Organ.

VIII. As for the *Wind-Gun*, which by means of *Air* only doth discharge *Bullets* with an extraordinary Violence, the same may be made after this manner.

Suppose C A, in the *Figure*, to be a *Brass Pipe*, or *Bore*; and let the end thereof, marked A, be well stopp'd, and be furnish'd with its *Stock*, and with two Keys I and K, so as that one of them may touch the other; and having open'd both the Keys, let a *Plug* be put in at the Mouth of the *Bore* C, by the help of a *Screw*, the Operation being several times repeated, in order to a stronger Compression; then let the Key K be shut home, and the other Key I be a little open'd, that by letting in of *Air* the *Plug* may be drawn forth; then let a *Bullet* be put into the *Bore*, with a little *Tow*, to keep it in; then open first the Key I, and afterwards K, and there will follow a forceable explosion or discharge of the *Bullet* at a great distance, by force of the Comprest *Air*.

IX. It is from the same Compression of the *Air*, that *Quicksilver* contain'd in a *Glass-Pipe*, open at one end and stopp'd at the other, remains suspended 2 Foot and a quarter high; whereas *Water* is rais'd to almost 32 Foot. For take a *Glass-Pipe* A B, 3 Foot long, being open at the one end A, and *Hermetically* sealed at the other B; let it be fill'd with *Quicksilver*, and turn'd upside down into the Vessel C D, also full of *Quicksilver*; it will clearly appear, that the *Quicksilver* will not sink down to the bottom of the *Glass*, but will continue suspended in the same almost 27 Inches high, at E. And the Reason is, because the *Quicksilver* cannot sink lower, but by pressing the *Ambient Air*, which being already condensed by that which lies upon it, and endeavouring to regain its former Expansion, strives against it, and by reason of the rowling of its complicated parts, cannot ply or give way. For tho' the *Quicksilver* be very heavy, yet can it not force the *Air*, consisting of thickish, vehemently extended, and continually rowling Parts, to a farther Compression.

X. Now that this Effect doth wholly depend on the *Elastick Power* of the *Air*, may be perceiv'd chiefly by this; because in the *Pneumatick Engin*, invented by Mr. Boyle, if the *Pipe* fill'd with *Quicksilver* be thrust into other *Quicksilver*, as soon as the *Air* is exhausted, the *Mercury* no longer continues elevated 27 Inches high; but sinks by degrees, and falls into the *Vessel*. But as soon as the *Air* is let in again into the *Engin*, the *Quicksilver* riseth again, and takes possession again of its former station.

XI. Yet we find that the *Air* hath not the same Force in all *Countries*, nor resists the weight of *Quicksilver* alike; but according as the same is purer, or more gross, so the sinking thereof is different. For tho' the *Air* be a *Liquid Body*, and be so ranged about the Center of the *Earth*, that its surface is of a *Round Figure*; yet because about the *Poles*, by reason of the great Cold it is more condensed, than in other places, it must needs be found there in greater abundance; and consequently must lye more heavily upon the *Earth* of those *Countries*, than upon those that are nearer to the *Aequinoctial*. Upon which account it is, that the *Quicksilver* sinks less in the *Glass-Pipe*, in *Holland*, *Denmark* and *Sweden*,

than in *France*, where the *Air* is more thin and rarefied; and more at *Florence* than at *Paris*: So that in the Year 1643, in which this Experiment was first tried, the *Quicksilver* in a *Weather-Glass*, at *Florence* in *Italy*, stopp'd at 2 Foot and almost 3 Inches: At *Paris*, at 2 Foot 3 Inches and an half; and in *Holland*, at 2 Foot, and 6 or 7 Inches.

And not only so, but this Rising and Falling differs also, according to the Change of the *Weather*; for we find that the *Quicksilver* in a *Weather-Glass*, sinks more in *Fair* than *Rainy* weather, and on a high *Mountain*, than in a low *Valley*, or any other place, where the *Air* is more Thick and Gross, and so strives more against the weight laid upon it. For the *Air* is condensed according to the Proportion of the weight of the *Air* that is above it, which is always so much the greater, by how much the *Air* is lower, and consequently it is necessary, that this Virtue be greater in that part of the *Air*, which is nearer unto the *Earth*, than in that which is farther from it.

From this Weight, or *Elastick Power* of the *Air*, proceed all those motions which are commonly ascribed to *Natures* abhorrence from a *Vacuum*, and may be readily explained by it: For no other Reason can be given why the *Water* riseth in a *Pump*, but only this, because it is pressed by the *Air*, that is about it, and so tends thither, where there is either very little or no pressure at all of the *Air*, viz. within the *Bore* of the *Pump*, out of which the *Plug* is pull'd; as hath been explained in our *General Physicks*, by many Instances.

CHAP. XV.

Of Meteors in General.

WE come now to treat of those things that are generated in the *Air*, commonly called METEORS: Which are nothing else but certain various impressions made upon the Elements, exhibiting them sometimes in this, and sometimes in another Form. And because for the most part they appear on high in the *Air*, they have got the Name of *Meteors* from their Elevation.

METEORS are Threefold, viz. Fiery, Airy, and Watry, according to the Predominion of that Element, which is most conspicuous in them.

FIERY METEORS, are those that consist of a fat, sulphureous kindled Smoak. And these are various, according to the diversity of their Figure, Situation, Motion, and Magnitude.

For when a Fat kindled Smoak appears in the form of a lighted Candle, wandering up and down, it is called an *Ignis Fatuus*, or *Will with the Wisp*: When it hath the appearance of a Cross Bar or Beam, it is called *Trabs*; when of a Pillar of Fire standing upright, it is called *Ignis Pyramidalis*; when its parts are of unequal thickness, the middle parts being thicker and broader, and the ends smaller, it is called *Draco Volans*, that is, a Flying Dragon; when the Fiery Meteor seems to skip like a Goat, appearing sometimes kindled, and at other times extinguish'd, it is called *Capra Saltans*, that is, a Skipping Goat. But the most wonderful and terrible

terrible of all the rest are *Thunder and Lightning*, of which hereafter.

IV. *AIRY METEORS*, are those which consist of *Flatuous and Spirituous Exhalations*, such as the *Winds* are.

V. *WATERY METEORS* consist of *Vapours or Watry Particles*, by the *Action of Heat* separated from each other, and variously modified. These are manifold.

VI. For if these *Vapours* be elevated above the *Earth*, and hanging in the *Air*, are either by a *West-wind*, opposing the ordinary motion of the *Vapours* Westward; or by *Two other Winds*, blowing from different *Quarters*; or by the alone *Coldness* of the *Air*, condensed and joyned into some small *Icy particles*, *Clouds* are generated. If these *Icy particles* chance to be resolved by the *Heat of the Sun*, or of some *Wind* blowing from a *hot Quarter*, and the *Wind* driven together, do entangle with one another like *Carded wool*, they make *Snow*; but if they be wholly melted into *Drops*, they constitute *Rain*.

VII. But when a *Cold wind* blowing congeals these *Drops*, when they are either altogether, or almost dissolved, they become turned into *Hail*.

VIII. If the *Vapours* hover near the *Earth*, they are called a *Mist*; which continues either till it be drawn upwards by the *Rays of the Sun*; or that by its own weight, or some other *External Cause*, it falls down to the *Earth*; where, by a less degree of *Cold*, it is changed into *Dew*, and by a greater, into *Hoar-frost*.

IX. There is another sort of *Meteors*, which are called *Appearing*; such as are *Mock-Suns*, *Mock-Moons*, the *Meteor* called *Virga*, in the appearance of a *Fire-brand* or *Rod*, the *Rainbow*, &c.

X. What these are, and how they are formed, take this short account: When the *Extremities or Ends* of a *Snowy Cloud*, being dissolved by *Heat*, are by a supervening *Cold wind* constricted into thin *Ice*, and such a *Cloud* as this happens to be opposite to the *Sun* or *Moon*, then is the *Image* of either of them reflected in the said *Cloud*, as in a *Looking-Glass*. That of the *Sun* is called *Parelius*, or a *Mock-Sun*; and the other of the *Moon*, *Paraselene*, or a *Mock-Moon*.

XI. Again, when a *watry Cloud* is compos'd of *Parts*, whereof some are more close and compact, and others more loose and lax, and the *Sun-beams* chance to pierce the more lax and open parts of it, then it exhibits a *Meteor*, representing a *Bundle of Rods*, which the *Latins* call *Virga*.

XII. Lastly, If a *Cloud* be resolved into small *Drops*, and the same be illustrated by the *Sun* plac'd over against it, then is form'd a *Semi-Circle* of divers *Colours*, called the *Rainbow*; whereof more hereafter.

CHAP. XVI.

Of *Meteors* in particular; and first, of the *Winds, Clouds, and Mists*.

WIND is a *Vapour* agitated and rarefied, which by passing from a narrow place, into one that is more large and wide, sensibly drives the *Air* before it.

The Name of *WIND* is improperly attributed to the *Agitation* caused by a *Fan* or a *Bellows*:

Neither can *Air* that is moved or rarefied by *Fire*, be called a *Wind*; seeing that the *Air* may be variously moved, when yet there is no *Wind* at all; as when *Drums* are beaten, or great *Guns* discharged. For we speak here only of a *Natural Wind*; which is nothing else, as hath been said, but an *Agitated Vapour*, which being distended, makes its way out of a narrower Space, wherein it was pent up, into a larger; and by this means sensibly driving the *Air* before it. If there chance to be a meeting of many *Vapours* together, then, according to the *Quantity of Matter*, the *Wind* is so much the greater, and diffuseth it self far and near.

VAPOURS derive their Original, not only from the surface of the *Water*, but likewise from the moist *Earth, Clouds, Snow, &c.* for the parts of these *Bodies* being not so firmly united, are easily disjoyned, and so break forth into the *Air*; where meeting with several *Exhalations* in their way, they together with the *Air* carry them along with them; because the *Air*, as well as *Exhalations*, contribute much to the Force and Violence of *Winds*. Tho' *Vapours* proceed promiscuously from the *Earth* and *Water*; yet the *Sun* shining raiseth more of them from the *Sea*, than from the *Earth*. And on the contrary, the *Earth* being heated with the *Sun-beams*, in the *Night* time, sends forth more *Vapours*, than the *Sea*; because the *Earth* longer preserves the heat of the *Sun*, than the *Sea*. Whence it is, that in the *day time* *Winds* are frequently perceived to blow from the *Sea*, and in the *Night time* more from the *Land*; as at *Jamaica*, and other of the *American Islands*.

Forasmuch therefore as the *Globe of Earth* and *Water* doth furnish a vast number of *Vapours* and *Exhalations*, which for the most dilate themselves between *Clouds, Mountains*, and other *Bodies* that are about them, by the force of this their dilatation, they rush from the places where they are streightned, into those where they find more Room and less Obstacles, and there vehemently tossing the *Air*, produce a *Wind*; much in the same manner, as we find that *Wind* is excited in *Eolipyles*. Suppose we therefore an *Eolipyle* A B C D E of *Brass*, all hollow, with a very narrow Orifice D, by which *water* is poured into it, the part A B C, to be full of *Water*; and other A E C, to contain nothing but *Air*. This *Eolipyle* being set near the *Fire*, as soon as it is thorough hot, many of the *watry Particles* begin to whirl round, and being elevated above the surface A C, and variously dashing against one another, rush through the narrow hole D, (where they find the least Resistance) with great Violence, and putting the *Air* into a great Commotion, they produce a *wind* from D to F. Thus we may know and judge by this little Instance, of the great and wonderful Causes of *Winds*.

For the Hollow of *Mountains* may be compared, to the Cavity of this *Eolipyle*: The *Heat* shut up in the *Bowels* of the *Earth*, to that whereby the *water* in the *Eolipyle* becomes dilated and elevated: The *water*, which the *Sea* by *Subterraneous Channels* conveys into the *Earth*, to that which is contained in the said *Vessel*: And lastly, the *Clefts* of the *Earth*, at which the *Vapours* and *Exhalations* come forth, to the Orifice thereof.

to be understood by the word, Wind.

III. Whence Vapours and Exhalations do proceed.

IV. How Winds are raised, by the Example of an Eolipyle.

Figure 50.

V. Mountains compared with Eolipyles.

thereof. Only with this difference, that the smallness of the Hole in the *Acolipyle* causeth the *Vapours* to rush forth with greater violence, than they do from the more open and manifold Clefts of the *Earth*. Yet doth not this hinder, but that sometimes *Winds* may have as violent a Blast, as that which is perceived to rush through the small Hole of the *Acolipyle*; because some *Mountains* are so situated, that the *Vapours* that come from them, can but go one way, which makes them move with great violence and swiftness. Tho' sometimes also *Winds* may rise in those *Countries*, where there are no *Mountains* at all, viz. when the *Vapours* that move from a higher to a lower Place, are by the *Clouds* or *Mists* they meet with, forced to discontinue their course, and to turn off side-way.

VI. According to the various parts of the *Horizon*, or *Quarters* whence the *Winds* blow, they are denominated *Cardinal* or *Collateral*. The *Cardinal WInds* are four, so called, because they blow from the four Corners of the *World*. The *East wind*, from the *Sun*-rising; the *South wind* from the *South*; the *West wind*, from the *Setting* of the *Sun*; the *North wind* from the *North*.

VII. The *Collateral winds* are those, which are inserted between two of the *Cardinal*; and these, according to the Account of our Modern *Seamen*, amount to 28; viz. 7 between the *East* and *South wind*, 7 between the *South* and *West wind*, 7 between the *West* and *North wind*, and as many between *North* and *East wind*. So that the *Cardinal* and *Collateral winds* put together, make up the Number of 32.

VIII. To the end that the Order of the *Winds* may be the better understood, it will do well to mind the *Figure*, where they are all set down by their usual Names. The first is the *North wind*, the second is the *South wind*, the third is the *East wind*, and the fourth the *West wind*; which are called *Cardinal winds*. The 4 that follow are called *Collateral*; each of which is placed in the midst of 2 *Cardinal winds*, and hath its Name composed of the 2 *Cardinal winds*, between which it is placed, viz. the *North-east wind*, the *North-west wind*, the *South-east wind*, and *South-west wind*. The 8 remaining *Winds*, which are placed each of them betwixt a *Cardinal* and *Collateral wind*, take their Denomination from them both: Thus that which is between the *North* and *North-east wind*, is called *North-North-east*; and so of the rest.

IX. The *East wind* is chiefly found to blow in the Morning, because the *Sun* heating the *Air*, doth dilate, rarefie, and makes it to move in one and the same *Country*; sometimes one way, sometimes another, according as he is placed with respect to that *Country*. For this diversity of Position produceth variety of *Winds*. As for Example, When the *Sun* riseth to us, he dilates the *Air*, as hovering perpendicularly over it, and doth so whirl it round, that one part of it rusheth towards the *West*, where we are; whence it is that we then perceive an *East wind*. On the contrary, when the *Sun* sets, the *Air* that is opposite to him becomes dilated, and thereupon one part of it must betake it self to the *East*, where we are then with respect to the *Sun*, and therefore must perceive a *West wind*. And the same happening in all the *Countries* that are situate without the *Torrid Zone*, it

follows, that in the Morning *East-winds* must blow, and at Even-tide *West-winds*: As I have exprest it in a *Figure*, in my *History of Nature*, Part VI. Chap. II.

And with the like facility a Reason may be given, why *North-winds* most frequently blow in the Day time; by observing that the *Earth* E B F D, under the *Poles* E F, where it is not much heated by the *Sun*, is surrounded with *Clouds* and *Mists*; and that at B, where the *Sun* sends down his direct and perpendicular *Rays*, many *Vapours* are raised, which are carried upwards till they come thither, where, by the force of their own weight, they are more easily turned Side-ways, to continue their way towards I, and M, above the *Clouds* G, and K, than to mount higher in a *Right line*. And forasmuch as these *Clouds* G, and K, become rarefied by the heat of the *Sun*, the *Vapours* proceeding from thence, do rather take their progress from G, to H, and from K, to L, than to E, or to F: For the thick and gross *Air*, which is under the *Poles*, makes a stronger resistance, than the *Vapours* that rise from the *Earth*, towards the *South*; for these being strongly pushed, and on all sides ready for motion, do easily give way to them. So that if we suppose the *Northern Pole* to be towards F, the motion of the *Vapours* from K, to L, will excite a *North wind* blowing in the Day time through *Europe*.

XI. Altho' the *Sun* ceaseth its Action in those *Countries*, where it is *Night*; Yet because the heat imparted to the *Earth* in the Day time, is for some time preserv'd in it, it so happens that many *Vapours* are thereby raised, which the *Air* at R, being condensed by the Cold of the *Night*, hinders from roaming towards Q, and R; like as those which are in the other part, wander towards I, and M; but they are there (for we suppose it to be *Night* in the part D) gather'd into *Clouds*, which hindring other *Vapours* raised out of the *Earth* from ascending to any great Height, do on every side beat them down towards N, and O, and so produce a *South wind*, which commonly riseth at *Night*.

XII. As *Winds* proceed from different *Quarters* of the *World*, so they differ in their Properties: For those that blow from the *East*, are more violent than those that proceed from the *West*; and this partly, because these comply with the motion of the whole *Body* of the *Air*; and partly, because the *Air* that is dilated and blows towards the *West*, tends to a place, where for 18 Hours it hath not been *Noon*: So that by this long absence of the *Sun*, the *Air* is much more condensed, than that to which the *Western winds* tend; because there it is not above 6 Hours since it was *Noon*, and the presence of the *Sun*, caused a great heat and rarefaction of *Vapours*.

XIII. The *North wind* for the most part is very strong and impetuous, because it is excited by the greatest heat, viz. that of *Noon-day*; and because it consists of a Matter that is most easily dissolved into *Vapours*, viz. *Clouds*. And for the contrary Reason, the *South wind* must be the most gentle, as well because the Thickness of the *Nocturnal Air*, is a stop to its Course, as likewise because the Matter whereof it consist, as proceeding from the *Earth*, or from the *Water*, cannot be so readily, nor so copiously dilated, as is the *Northern matter*, which

which, as we have already said, is pour'd forth from the Clouds.

XIV.
The East-
wind is
more dry
than the
West.

As to the other Qualities of the Winds, it is notorious that East-winds for the most part are dryer, and produce a more serene and clear Air, than those that come from the West; because these latter, by striving against the Natural Course of the Vapours, do stop them, and drive Clouds together, whereas the former do dispel and dissipate them.

XV.
Which
Winds are
said to be
Dry, Moist,
Hot and
Cold.

Hence it is evident, that the North-wind is of a more drying Quality, that is, hath a power of driving watry Particles out of the pores of Bodies, or from their Outfides, whilst they are expos'd to the Air; because, for the most part, it is compos'd of the grosser parts of Fresh-water, mix'd with the Air. The same Wind is likewise cold, because it carries along with it the most subtil Northern matter, towards the South, which is the Primary Cause of Cold. But the South-wind is hot and moist: Moist, because it consists of the more gross, and subtil parts of Fresh-water, elevated together from the Earth: And it is Hot, because it brings along with it the Subtil matter, which was in the Southern quarter, towards the North. For the Winds are much alter'd, according to the place through which they pass; and therefore, according to the Nature of the Region through which they go, are either Hot, Cold, Moist, or Dry.

XVI.
The Regu-
larity of
the Winds
is some-
times hin-
dered by
particular
Causes.

All these things we have here spoken concerning the 4 Cardinal-winds, would happen so continually, if the Earth in all its parts lay equally above the Water, and there were no difference of Soils and Springs, nor any other Cause, but the presence of the Sun, to dilate the Vapours; but there are so many other Causes that conduce to the production of Winds, that it is no wonder to find them so irregular, and not to rise in the same Order. Wherefore we cannot with Reason expect Regular winds, save only in those parts of the Sea which are most remote from the Land. Forasmuch as there is no such great inequality in the surface of the Sea, as there is in that of the Earth; and because the Winds, which are driven that way from the Shoars, very rarely can reach so far, as to disturb the Course of those Winds that blow there.

XVII.
What
Winds are
called Pe-
rennes, or
Continual.

Besides the foremention'd kinds of Winds, some Winds are called Perennes, that is, Continual; others Stati, or such as blow at certain Times and Seasons; others, Provincial; and others, Free.

The Continual Winds are 2; the one in the Torrid Zone, which continually blows from East to West: The other in the Temperate Zones, which, as far as about the 40th Degree, blows also from the East to West. These Winds are very observable at Sea, but are scarce discernible at Land.

XVIII.
What Venti
Stati are,
that is,
such as
blow at
certain
Seasons.

Winds, Named by the Latins, Stati, are such as return at certain and set Times. The most famous of this kind are the Winds called Etesiae, which return every Year, towards the end of July, and continue 40 Days together, especially in Italy and Egypt: They blow at Night, about 3 hours after Sun-set, and for the most part cease at the approach of the Evening. Their Course is from the East or the North, or from between them both.

Provincial Winds are such as blow in certain Provinces or Countries: Such is the North-wind, that blows on the North-side of the Alpes, according to the Course of a River, about 1 or 2 Leagues in length, but much less in breadth. This is a Daily-wind, and seems to blow continually, and with great evenness, like a River.

XIX.
Provincial
Winds.

Those are called Free-winds, which without any order of time or place, do blow from different Quarters. Thus the West-winds blow most commonly about Noon, or after, when the Sun is halting towards its setting. The South-wind frequently riseth at Night, and blows more vehemently than in the Day time; whereas the North-wind blows more in the Day time, than at Night.

XX.
Free Winds.

As Vapours that are dilated in the Air, do produce Winds; so when they are compress'd and condens'd, they make Clouds. Which then happens, when their motion is diminished; for then their little Particles come closer together, which as soon as they are joyned, rise up in little heaps, and these gather'd together compose vast Bulks. For the Clouds are nothing else, but Vapours and Exhalations sublim'd so high, that the Coldness of the Air makes them come together, and so to constitute a Whole, which is so loose and spongy, that it cannot by its weight overcome the Resistance of the Air, which opposeth its descent.

XXI.
The Original
of
Clouds.

Clouds do often interrupt the Action of Light; for tho' the Drops of Water, and the flocks of Ice whereof they consist are singly transparent; yet their multiplied Surfaces do repress the Light of the Sun. As appears in Froth, which because of the various surface of its Parts, cannot receive the Light. The Cause of this Condensation is, either the Winds which compress the Vapours together, especially if they be opposite, and blow from divers parts; or else the figuration of the Particles that compose the Vapours, whereby they are more fit to cling and close together.

XXII.
How Clouds
come to
darken the
Light of
the Sun.

The Reason why Clouds do not fall down out of the Air upon the Earth, is, because their Particles are very thin, and have large Surfaces, their Matter consider'd, and therefore are easily born up by the Air, which is ever thicker near the Earth; or else are hinder'd by the Winds from coming down: Much in the same manner, as a deep laden Ship, is born up by the weight of the Water. Hence it is, that according to the less, greater, or equal weight of a Cloud, it doth either ascend, descend, or hang equally pois'd in the Air; even as a Ship, proportionable to its less, greater or equal Gravity, doth rise, sink, or is evenly pois'd in the Water. But when the particles of the Clouds are so thick, that they can no longer be kept up by the resistance of the Air, then are they resolv'd into Water, and by their weight fall down to the ground.

XXIII.
How Clouds
are support-
ed in the
Air.

A MIST differs from a Cloud, only by the diversity of its place; for Mists are Vapours that reach to the very surface of the Earth; whereas those that constitute the Clouds are pois'd in the Air. For a Mist is nothing else, but a Dusky Vapour, hovering on the Earth, which continues either till it be drawn up by the Rays of the Sun, or by its own weight, or some other outward Cause, falls down to the Earth.

XXIV.
The diffi-
rence be-
tween a
Mist and
a Cloud.

XXV. We are to take notice that the Parts of Ice, whereof I have said that Clouds consist, are not so joyn'd together; but that there is some distance between, so as to make up several little Heaps: So that if they chance to be shaken with any strong Wind, they are easily separated, and fall down to the Earth. If these *Hillocks* or *Flocks* are not wholly dissolved, they make *Snow*. But if the Air, through which they are carried, be so hot as to make them to melt, they come down in *Rain*. It happens also sometimes, that after they are turn'd into Drops of Water, a Cold wind meeting with them, congeals them into *Hail*; for *Hail* is nothing else but frozen or congealed *Rain*.

CHAP. XVII.

Of Rain, Dew, Hoar-Frost, and the Cool Evening Air.

I. **R**AIN is nothing else, but those Drops into which a Vapour elevated above the Earth, is resolved. We have a resemblance hereof in distill'd Liquors; for the rising Vapour, being condensed by the Coolness of the Air, returns to its former state, and runs together into Drops, which at first are insensible, but in their falling do wⁿ are commonly increased, by others joyning with them; and those commonly are the largest, that fall down from the highest place.

II. We must not therefore suppose, as some do, that Rain is produc'd in the Air, as Water; that by being poured from on high, becomes disperst into many Drops; or that it is generated in manner of a Pool, the Water whereof falling from the Clouds is dissolv'd first into greater, and then into less Drops; but only by degrees and by parts: For the Drops of Rain, are formed of the particles of Vapours joyning together, and being joyned fall down to the Earth. Hence Rain hath got several Names, according to the different bigness of the Drops, whereof it consists: For the Rain that falls down in small or midling Drops, is called by the common Name, *Rain*; if it drops very small, 'tis called a *Drizzling Rain*; if it falls down in great Drops, and those close and thick, 'tis called a *Shower*; if it comes down in great Drops, and fiercely, 'tis called a *Storm*.

III. The Drops of Rain are great, when the Heat acts upon the upper part of the Cloud; because then the Drops that descend do increase in their passage, by the addition of other Drops they meet with from the top of the Cloud to the bottom: Whereas on the contrary, when the action of Heat is only exerted on the lower part of the Cloud, as it commonly happens in the Winter, the Drops are so small, that they are not called Rain, but only a *Mizzling Dew*.

IV. Tho' it be evident enough how Clouds, that consist only of Watry Drops, come down in Rain, viz. either by their own weight, when the Drops by the coalition of many particles, have attained to a sufficient thickness; or, when that the Air that is under them, by its withdrawing, or that which is above, by pressing upon them, inclines them to a descent; or, when many of these Causes chance to concur: But yet it is not so evident to all,

how Rain is generated at first out of a condensed Cloud.

Now this will be easily made out, if we consider how 2 contrary Winds do gather great abundance of Vapours into the middle Space between them, and thereby cause the production of a Mist or Cloud there. For let us suppose, for Example, a Wind to blow upon the Earth AB, from the West D, and another to blow the contrary way, from the East C, so as that both these Winds come to stop one another about the Space FGP; it must necessarily follow, that the Vapours intercepted between the wind D, and the wind C, being driven together, must be there condensed, and make a kind of confus'd Mass. In like manner the Wind that drives against this Cloud, yet not with that Violence as to carry it along with it, must drive the parts of it closer together; by which means many of the watry Particles, which before were insensible, and separate from each other, are by the force of the wind driven together, and so become great Drops, which by their own weight fall down. For as in your common Stills, Drops are not formed as soon as the Vapour is got to the Head of them, for that other Vapours ascending to the top of the Still, must increase their bulk. So neither can Rain be generated, as soon as the Vapours are got up to the Region of the Clouds; but it is necessary, that those Particles of which the Vapours do consist, be by the Wind driven together, and more closely joyned; and that being thus become more heavy, so as to be able to vanquish the resistance of the Air, they fall down to the Earth.

Notwithstanding that by this way Clouds are often turned to Rain, yet is the Heat of the Air a more frequent and efficacious Cause of it. For this heated Air clinging to the Clouds, makes the subtil Snow, whereof they consist, to dissolve, and separates it into many little Flocks, which have then force enough to drive away the Air that opposeth their descent; and so by the action of the Heat they meet with in their passage, they are quite melted, and turn'd into Drops: Which sometimes are large, when the Cloud is thick and close, and comes down by the pressure only of the Air that is above it; because the upper Drops meet with others in their way downward, that increase them and make them larger, as before hath been mention'd.

The Drops of Rain, as they fall down, are made round: For a Liquid Body then becomes Round, when all its Parts are by an equal force driven towards some Common Center; for all the Parts of that Circumference being moved by a like force, are at an equal distance from the Center. Now Rain is a Liquid Body, all whose Parts, when the Air is calm and free from Winds, are compress'd by an equal Virtue to some Common Center. For the Calm Air doth on all sides equally compress these Drops, there being no Reason to be given why it should press them one way, more than another.

Having premised thus much concerning Rain, it will not be difficult to conceive how the DEW is formed, if we observe that when the Air is clear and not ruffled with Winds; many loose and thin little Bodies are disperst abroad, especially in the Summer time, when Vapours and Exhalations are copiously elevated from the Earth:

Which

V. Rain is sometimes caused by Wind.

Figure 53.

VI. The more common Cause of Rain is Heat.

VII. Why the Drops of Rain are Round.

VIII. How the Dew is formed.

Which small Bodies flying in the Air, in the form of Vapours, when the cold of the Night comes on, do lose their agitation, and many of them clinging together, produce insensible Drops, which falling down upon the Dry ground are suck'd up, but falling upon the Leaves of Trees, or the Spires of Grass, are there gather'd into greater Drops. This chiefly happens in the Night, or before Day-break; because then the Earth is most cold, as being turned from the Sun. Whence it follows, that the Dew is nothing else, but certain Vapours, that have by Heat been elevated in the Day time; and which being condensed by the Coldness of the Night, fall down in small insensible Drops upon the Leaves of Plants; where many of them joining together, they become sensible.

IX. HOAR-FROST is generated, when the Vapours, that are near the Earth, are congealed by the coldness of the Night: Which only happens in the Winter, when Cold predominates. For tho' when the Coldness of the Night is yet temperate, it be sufficient to compress the watry Particles up and down dispers'd through the Air, into sensible Drops, yet not to congeal them. But the Cold of Winter-Nights being more intense, congeals the said Drops in the form of Snow or Hail. So that it appears, that the difference between Dew and Hoar-Frost is this, That Mists do turn to Dew, if they consist of Drops of water; but into Hoar-Frost, when they consist of Vapours that are frozen before, or are congealed in their passage down to the Earth.

X. It is observed, that the Hoar-Frost makes some Herbs, and particularly Coleworts, tender; the Reason whereof is, because the Cold acting upon them, doth very much condense them, and causeth many humid Particles to congeal together; which afterwards are easily resolved again by any super-vening Heat, and by this means their fibres become in a manner clean dissolved, which is the cause of the Tenderness of those Plants. The like also happens in Flesh, which having been frozen, doth thereby grow very Tender.

XI. As to that COOL EVENING-AIR, or Breez, which is consequent to fair Summer-days, we find that it commonly happens when the Heat of the Sun hath been very intense all the Day long, and thereby greatly agitated the Air; by which means the surface of the Earth also is moved to send forth abundance of subtil Exhalations upwards, to the Region of Vapours; and because these Exhalations do more easily lose their agitation, than the Vapours do, as soon as they are deprived of the Sun's Heat, the former of these fall down. And herein doth chiefly consist the Nature of this Cool Air, or Breez; which according to the difference of places, is endued with different Qualities: For it is probable, that these Particles which exhale from places Infected, or poisonous Plants, are far more hurtful, than simple Vapours that arise out of the Earth.

XII. The Cool Air, or Breez of the Evening, is never more hurtful, than when the Day fore-going hath been very clear, and the Heat of the Sun moderate: For the immoderate Heat of the Day doth much extenuate these Vapours, and elevates them on high, so that they cannot so readily be condensed by the Cold of the Evening. It is also very hurtful after that the Sun is set, because the

more heavy Exhalations, which have less of Vapour mix'd with them, as soon as they are left destitute of the Sun-beams, do immediately come downwards.

The Air cover'd with Clouds, is a sign of Rain, if the Sun shine in the Morning; for this is an evident Token, that there are no other Clouds in the Neighbourhood of our Air, towards the East, which can hinder the heat of the Sun from condensing those that hang over our Heads, or from raising new Vapours, whence they might be increased, out of the Earth. But this Cause only takes place in the Morning; for if it do not Rain before Noon, it cannot afford any signification of what is to happen in the Evening. Neither are those signs, which are taken from the Croaking of Frogs, or Crows, the Praesentations of Beasts, the Redness of the Sun, the Paleness of the Moon, and other such like, any whit more certain, but generally very fallacious: And he that would take the pains to observe them diligently, will frequently find the contrary, to what is commonly expected from such like Praesages.

Yet we find, that when no Dew falls in the Night, or the Mist is carried upwards, leaving the Earth destitute of all Moisture, this is a sign of Rain; because this seldom happens, but when the Earth, having not been sufficiently cooled in the Night-season; or been agitated by too much heat in the Day time, doth send forth abundance of Vapours, which driving the Mist upwards, make its Parts to run together; by which means they become so great and weighty, as that they are forced to come down in Rain.

CHAP. XVIII.

Of Snow and Hail.

SNOW may be said to be a dissolved Cloud, which being driven downwards by its own weight, falls down to the ground in Flocks. It is said to be a Dissolved Cloud; because a Cloud is nothing else, but a great heap of Snow close clinging together. And it is said to be Dissolved, because when the union of the parts of a Cloud are broken by force, one part of it becomes sever'd from its next part, and being more weighty than the Air, comes down in the form of Snow or Rain. It is said in the next place, that it is driven downwards by its own weight. For a Dissolved Cloud, by its own weight, either turns to Snow, Rain, or Hail. And lastly, it is said, that it comes down in sever'd or distinct Flocks. For as a Flock of Wool, consists of many particles of Wool, entangled together; so the Flocks of Snow are compos'd of many Shaggy particles clinging together.

It is not always necessary, that the parts of Clouds should be wholly melted before they come down, since it is common for them not to be dissolved, or to turn to Drops, before that they come near the Earth, where the Heat is strongest, as exceeding that which is on high. Wherefore, when the parts of a Cloud that are only condensed, without being melted, do meet with the cold Air, which is no longer able to bear them, they fall down with their own weight, and that in Flocks of Snow, and not in Drops.

XIII. If when the Air is dusky, the Sun shines in the East, it is a sign of Rain.

XIV. When no Dew falls in the Morning, it is a sign of Rain.

I. What Snow

II. How Snow and Hail are formed, and why they are white.

III.
How the
Snow,
whereof
Clouds con-
sist, is
condensed.

To understand the way how the *Clouds* come to be condensed, we are to suppose that the *Heat* which commonly rarefies most *Bodies*, doth notwithstanding condense that of *Snow*; whose *Parts* are so separate from each other, that the least agitation is sufficient to bring them together. Whence it comes to pass, that when the *Air*, which is near the *Earth*, and is always more hot, than that which is at a greater distance from it, comes to elevate it self to the *Clouds*, either by the Force of some *Wind* that carries it along, or by the Action of some new *Fermentation*, which causeth it to swell, it is necessary that it condense the *Snow*, whence the *Clouds* are composed.

IV.
How Hail
is produc'd,
and what
is the fi-
gure of it.

The *Flocks* of *Snow* are of a *white Colour*, because the *watry Matter*, whereof they are composed, contain a great deal of *Air*; and its *pores* are so disposed as to reflect the *Light*, rather than to afford it a free passage, as *Ice* doth. But if these small *Flocks*, after that they are melted by warm *Air*, do afterwards meet with other *Air* that is cold, and by it are congealed; then they turn to *Hail*, whose *Stones* are of a different Figure, according to the various Solution of the *Flocks*. For if the *Cold wind*, that congeals the *Hail*, doth meet with the *Flocks* of *Snow*, when they are almost dissolved, but not yet rounded into *Drops*, then they obtain an *Horned figure*; and when the *wind* meets with the *Drops* of *water* already formed, it produceth little transparent round *Pellets*, save only that commonly they are somewhat flatish on that side where the *wind* beats upon them.

V.
Why the
Hail is
sometimes
of a Coni-
cal figure.

So that from the divers degrees of *Heat* where- with the *Air* is agitated, and whereby the *Cloud* must be dissolved, there ariseth a great variety of *Effects*. For if the *Heat*, which by the *Cold wind* is driven into the *pores* of the *Flocks*, and penetrates their inmost *Parts*, chance to drive them towards the *Center* and condense them, whilst the *External parts* being become stiff and bound by the *Cold*, cannot follow, they must of necessity be slit, according to *Right lines* tending to the *Center*; and as the number of these *Slits* do increase, as the *Cold* penetrates deeper, they must at last fly in pieces, into many longish and *Pyramidal particles*, which are so many *Hail-stones*, which at the first approaching of *Winter*, fall down to the ground, especially if a *Spring-like* constitution of the *weather* have gone before.

VI.
Why it
seldom
Hails in
Winter.

For it is apparent, that it cannot *Hail* much in the *Winter*; or if it doth, the *Stones* cannot be great. The Reason is, because during that *Season* there is seldom *heat* enough so high as the *Clouds* to melt them; but only when they are so low, as that being melted, or near melted, they have no time to be congeal'd again before they reach the *Earth*. Whence *Hail* may be described to be a *Cloud* that is melted, either whole or in part, and being driven downwards by its own weight, becomes so congealed by a *Colder wind*, that it falls down commonly in round and transparent *Pellets*.

VII.
Whence the
different
Figures of
Hail do
proceed.

The *Hail-stones* are sometimes of an *Oval figure*, viz. when a melted or dissolved *Cloud* is stronger compressed on one side, by the *wind*, than on the other. Sometimes they are rough, by reason of many *Angles*, which happens when a *Cold wind* seizeth the *Flocks* of *Snow* as they are melting, but before they are turn'd into round *Drops*

of *Rain*. To which may be added, that the *Hail-stones* are sometimes so violently dash'd against the *Earth*, as thereby to be broken to pieces, and so lose their Natural figure.

But much more wonderful is the figure of *Snow*, which sometimes is *Hairy*, as in M and Z, sometimes *Six-corner'd*, and consisting of 6 equal *Rays*, like *Stars*, as in O; sometimes like a *Rose*, as at Q; sometimes in the figure of 6 *Rays*, or like 3 *Rods* laid Crosswise, which like greater *Branches*, shoot out lesser *Branches* from them, the broadest whereof are nearest to the *Center*, so as to reach and entangle one another; and the shortest or narrowest towards the *Top*, making a *Corner'd* or *Angulous Ray* or *Beam*, as in R.

HAIRY-SNOW MZ, is produc'd, when the particles of *Ice*, which constitute the *Flocks* of *Snow*, being condensed by the heat of the *Air*, and several times after congeal'd by the *Cold*, whirl round their own own *Centers* in the *Air*: In which motion they are cover'd with some longish and slender particles of *Ice*, as with *Hair*, and so exhibit the figure of *Hairy-Snow*.

Snow of a 6 *Corner'd* or *Starry figure*, O, is formed, when the *Wind*, which hath dispos'd the *Flocks* of *Snow* into the form of *Leaves*, by passing freely betwixt them, doth melt the particles of *Waters*, that stand upright like *Hairs*; so that afterwards insinuating it self into the 6 *Corner'd Spaces*, it melts the most subtil and loose *Snow* that is about the *Circumference* of them; and the particles of *Water*, being agitated by the force of heat, joyning themselves with others that are not melted, do presently congeal them; and so their *Hair-like Extremities* being bent this way and that way, the *Flocks* grow less, and are changed, as it were, into a small plate of *Ice*. And as to those *Hairy prominences*, which are melted in the *Circumference* of these *Intervals*, these become condensed, whilst they withdraw themselves towards those which joyn every one of these *Flocks*, to 6 others that surround it: By which means 6 *Breaches*, or *Slits*, are made in the 6 parts of the *Circumference*, where the *Heat* is most predominant.

Snow is formed into the figure of a *Rose*, Q, when the *Heat* of the *Air* is somewhat greater, than what we just now supposed: For then dashing against these 6 prominent *Points*, it makes them shorter; and causeth the plate of *Ice*, which before resembled the figure of a *Star*, to become like a *Rose* with 6 *Leaves*, the points being rounded like the *Teeth* of the *Wheels* we see in *Watches*.

If the *Flocks*, whereof *Snow* is composed, be bigger than ordinary, it may happen that by this means it may be not only divided into 6 places, in order to the forming of 6 points; but that also every one of those 6 points, be divided into 6 others, by the intervening of 2 *Breaches* or *Slits*, from the *Hairy prominences* or *Capillaments*, which reach the *Capillaments* of another *Flock* of *Snow*: So that by this means 2 points might be formed, bending outwards; because the *Heat* there acting with more vehemence, produceth a greater *Condensation*: And thus instead of one *Starry-point*, or a *Rose-leaf*, there must appear the *Leaf* of a *Lilly*, as is represented in R.

This Plate is humbly

Dedicated by Richard Blome

XIII. Some of these *Snowy Stars* are white, like refined Sugar; and others of them are Transparent. The *Whiteness* of them proceeds from the *Mediocrity* or *Temperateness* of *Heat*; as when it hath not force enough to pierce to the *bottom* of the *Matter* whereof they are composed. Or because in their passage through the *Air*, they have joyn'd to themselves some *particles* of *Water*, before they got down to the *Earth*. Whereas other *Flocks*, that are more thin and small, are *transparent*; because the *Heat* hath wholly penetrated them, and made their *particles* to come nearer, and to be joyn'd more closely together.

XIV. One thing remains still to be noted, *viz.* that there is seen a *white Point* in the *Center* of the *Rosie-Snow*, as is represented in Q. The Reason whereof may be, because the *Heat* that hath formed these *Stars*, is so moderate, that tho' it makes all their other *parts* pellucid; yet not being strong enough to pierce to their *Center*, it leaves them *white*.

CHAP. XIX.

Of Thunder, Lightning, and Coruscation, or Flashes.

TO the end that the Nature of *Lightning* and *Coruscation* may be the better understood, we must premise something concerning *THUNDER*; for usually they are *Concomitants* of it, and depend on it, as their *Cause*. Now *Thunder* is produc'd, when many *Clouds* rush down upon others that lye directly under them. For it comes to pass sometimes, that the highest *Clouds* being condensed by *Heat*, and made more weighty, fall down upon others that lye under them, and cause that Noise which we call a *Thunder-Clap*. For it cannot be question'd, but that in the *Summer time* especially there are abundance of *Nitrous*, *Fat* and *Sulphureous Exhalations*, in the *Air*. It is certain also, that *Snowy Clouds* are condensed by *Heat*, and thereby become more Heavy. It is also as apparent, that all *Clouds* are not of the same height, but some higher, and others lower; since besides *Reason*, *Sense* it self comes to confirm it, which often shews us one *Cloud* moving over another. These things being thus presuppos'd, we proceed to the Explication of *Thunder*, *Lightning*, and *Coruscation*.

II. When any *Clouds* condensed by *Heat*, and by this means being become more Heavy, rush down upon an *Inferiour Cloud*, the intermediate *Air* being thereby strongly agitated, is the cause of a *dreadful Sound*, which is called *Thunder*. For let us suppose two *Clouds* A and B, composed of loose and much dilated *Snow*; let us also suppose, that there is a warmer *Air* about the upper *Cloud* A, than about the lower *Cloud* B; it is evident, that for this Reason it must be more and more condensed, and consequently become more Heavy: So that its most outward *parts* falling down first, push others they meet with in their way, and hurrying them along with them, do at last rush down all together, with great Violence, upon the *Lower Cloud*, with a dreadful rumbling Noise.

III. I have said, that *Heat* condenseth the *Clouds*: For tho' *Heat* do rarefie some *Bodies*, yet

it ordinarily is wont to condense *Clouds*, as hath been said of *Snow*, which consists of the same *matter* as a *Cloud* doth. For if *Snow* be laid in a warm place, it contracts it self into a less *Figure*, before that any *water drop* from it, or its weight be diminished. The *Clouds* therefore being thus condensed, do easily descend, and oppose the passage of others that moved upwards, by reason of their Looseness, and thrust downwards whatsoever opposeth them in their way. And forasmuch as this cannot be without a violent concussion of the *Air*, therefore it is accompanied with that terrible Noise, the resounding *Air* making it still louder.

Thunder therefore is a Noise excited by the *Air*, which hath been intercepted between two *Clouds*, whereof the Upper falling upon the Lower, and which being forc'd to retire thence, by the weight of the middle part of the Upper *Cloud*, which continues to come down, forceth for it self narrow and irregular *Gaps*, to get out by, which produceth a dreadful *Sound*, being much augmented by the Rarefaction caused by the enkindling of the *Nitrous Sulphours* betwixt these 2 *Clouds*.

It *Thunders* but rarely with us in the *Winter* time, because then the *Heat* that is sufficient to dissolve the Upper *Clouds*, cannot reach so far. But in the *Summer time*, when the *Heat* is violent, and more especially when the *North-wind* makes the *Heat* to be more close and stifling, *Thunder* is produc'd; because this *wind* is wont to carry the heated *Air*, that is near the *Earth*, upwards, to those higher *Clouds*; by which means not only those *Superiour Clouds* are condensed and rush'd downwards, but also the *Lower* continue so loose and dilated, and by the Dilatation of the *Air* that is under them, are so thrust upwards, that they, as it were, meet the others falling down upon them, and stop them there, hindring any part of them from coming down to the *Earth*.

Thunder is commonly follow'd by a *Shower* of *Rain*, and when the *Rain* is very copious, it is a sign that little more *Thunder* will follow; because when the Force wherewith the Upper *Cloud* rusheth down from the Lower, is strong enough to make it come down wholly, the *Thunder* must needs cease: And if it be not strong enough, and the *Lower Cloud* dissolves into *Rain*, the same thing will still happen; because the *Air* that is shut up betwixt the 2 *Clouds*, can now with ease get forth, because of the small resistance of the *Lower Cloud* dissolving into *Rain*.

The *Sound* of *Bells*, and of *Canons* discharged, makes *Thunder* to cease; because thereby the *Air* is strongly agitated, and communicating its motion to the Neighbouring *Air*, and that again to the Intermediate, till it reach and shake the *Snow*, whereof the inferiour *Cloud* consists, occasions its descent. Which Experience makes evident to those, who are us'd to Travel in those *Vallies*, where the falling down of heaps of *Snow* from the *Hills* is apprehended; for fearing lest the *Sound* of their Voice, by shaking the *Air*, should bring down the *Snow*, they are afraid so much as to Cough, to prevent that danger.

denfeth the Clouds.

IV. What Thunder is.

V. Why Thunder is much more frequent in Summer, than in Winter.

VI. Why every Clap of Thunder is commonly follow'd by a Shower of Rain.

VII. The Noise of Bells conduceth, to make Thunder cease.

VIII.
What is
the Cause
of Coru-
sation.

The *Exhalations* that are found in that Space which is between the 2 *Clouds*, are the matter of *Coruscations* and *Lightning*, and according to the degree of *Rarefaction* and *Condensation*, produce either the one or the other: For *Coruscation* proceeds from an abundance of very subtil *Exhalations*, and very inflammable. For these subtil and sulphureous *Exhalations* in the *Air*, become kindled by this *Agitation*, by reason that the Matter of the first Element being by this Concussion deliver'd from its Bonds, doth most swiftly run through them, which is the Reason of those *Flashes*. This does frequently happen after great *Heat* and *Droughts*; for then by the dashing together of *Light Clouds*, a *Flame* is kindled and breaks forth, which often reacheth our *Eyes*, without the bearing of any *Noise*; because the *Clouds* dashing against each other, is too soft to be heard at so great a distance.

IX.
What is
the Cause
of Light-
ning.

But if the *Exhalations*, which are intercepted between 2 *Clouds* rushing against one another be thicker and closer, then with great vehemence breaking through the shatter'd *Clouds*, and obliquely darted down to the *Earth*, they constitute the *Lightning*; by which (according to the condition of its own Matter, which sometimes is more thick, or gross and copious, and therefore more Violent; and at other times, more subtil and in less quantity, and so more penetrative; or of the matter of its Objects, whereof the more hard and solid, do make a greater and stronger Resistance, because they cannot give way, and so are dissipated by it: Whereas the softer and porous Objects do easily give way, but withal more readily take Fire) those wonderful and stupendous Effects are produc'd, which strike Mens *Minds* with Astonishment, and force the most impious *Minds*, tho' fore against their wills, to revere the *Divine Power*.

X.
Of the
Thunder-
bolt.

It is commonly believ'd, that besides the *Coruscation* and *Lightning* which proceed from the 2 *Clouds*, there comes forth also a hard *Stony substance*, which is called a *Thunderbolt*, tho' it is own'd that the same is not always discharg'd, as oft as it *Thunders*; but some think this is only asserted, and not proved. Yet if any such thing should be, we must suppose it to be generated of some gross Matter, which in its descent, hath by the great *Heat* been reduc'd to that hardness.

XI.
How the
Lightning
differs
from Co-
ruscation.

The difference between *Lightning* and *Coruscations* or *Flashes*, is this: *Coruscations* or *Flashes*, may be caused by *Exhalations* that lye under one *Cloud* only; whereas *Lightning* doth not proceed, but from such *Exhalations* as are intercepted betwixt two or more *Clouds*. Because *Lightning* is an *Exhalation* with a great force breaking through the *Clouds*, which cannot be, but by *Clouds* that lye one upon another, when by the heavy fall or rushing down of the upper *Cloud*, the *Exhalations* are kindled, and through a Breach made in the *Lower Cloud*, are darted downwards towards the *Earth*. We must conceive that the whole *Upper Cloud* rusheth down upon the *Lower* equally and altogether; for then it *Lightens*, by reason of the kindled *Exhalations* breaking through the *Lower Cloud*.

XII.
The Defini-
tion of

For *Flashing* or *Coruscation* is nothing else, but an *Exhalation* spread under a *Cloud*, which by the

motion of the said *Cloud* rushing downwards, is set on fire, and flasheth. Much after the same manner, as a *Torch* newly put out, and yet smoaking, is by some violent and sudden motion again enkindled. But *Lightning* is an *Exhalation* intercepted between two or more *Clouds*, which by the Heavy Fall of the Superiour *Cloud* is not only kindled, but through the *Lower Cloud* is thrust down to the *Earth*.

The *Lightning* doth more frequently strike the Tops of the *Mountains* and *Steeple*s; for seeing that the *Clouds*, where the *Thunder* is generated, are high, and that the breach is usually made at the end of them; it cannot well be conceived, but that the *Exhalation* that breaks forth thence, rushing down slantingly, must needs meet with the highest *Bodies* first. To which we may add, That if 2 *Clouds*, whose Ends are separate from each other, were to open in the Lower part of them, we must suppose that it would rather happen in that part which answers to the High *Body*; because the same, by hindring the descent of the *Air*, doth determine it by its Resistance, to break rather in that place, than in any other.

The various Effects of *Lightning* are to be attributed to the composition of the several *Exhalations*. It burns the *Cloaths* or *Hair* of a *Man*, without touching his *Body*; because the *Exhalations* whereof it consists, is of the nature of *Oil*, whose flame is weak. Sometimes it melts the *Gold* that is in a *Mans Purse*, and the *Sword* in the *Sheath*, without hurting the *Purse* or *Sheath*; which happens, because the *Exhalations* are very subtil, as participating of the Nature of *Salt* and *Aqua-Fortis*, by which means they pass through porous *Bodies* without any Impediment or hurt to them; but dissolve whatsoever resists entrance. As we find much the same effect of *Aqua-Fortis*, which dissolves the *Hardest Bodies*, and yet leaves *Wax*, and other *Soft Bodies*, in a manner untouched.

CHAP. XX.

Of the *Rainbow*, *Circles* about the *Sun* and *Moon*, and of *Mock-Suns* and *Mock-Moons*.

THE *RAINBOW* may be defin'd a *Bow* of diverse Colours, which the opposite *Sun* paints on Drops of *Water* by a various Modification of his *Light*. It is called a *Bow*, because it is represented in the figure of half a *Circle*. For the *Rainbow* is a portion of that *Circle*, which is drawn from that *Line*, as from its *Center*, which passeth from the *Sun*, through our *Eye*, called the *Axis Visorius*. It is said to be of many Colours; because of the several Colours which may be discern'd in it. And lastly, it is said, That the opposite *Sun* paints, or represents it, in Watry Drops, these being indeed the Matter of a *Rainbow*.

We shall the better be able to understand the nature of a *Rainbow*, by taking a view of all the particulars that are contained in it. First then, we say that the *Rainbow* is represented in a *Dewy Cloud*. Secondly, That the *Dewy Cloud* consists of innumerable drops opposite to the *Sun*. Thirdly, That

ning.

I.
The Defi-
nition of a
Rainbow.

II.
What
things are
to be noted
in a Rain-
bow.

That every one of these drops are like a *Globe* of *Glass* filled with *Water*. Fourthly, That all and every one of these drops, being heavy, and consisting of particles of water joined together, are carried downwards. Fifthly, That the *Rainbow* is produced in such a manner in that part of the *Air*, which is opposite to the *Sun*; that the *Spectators* are in the middle between them, so that if a line drawn from the *Sun* to the *Eye* of the *Spectator*, should be continued, it would pass through the *Center* of the *Rainbow*, and consequently that the *Center* of the *Rainbow*, the *Eye* and the *Sun*, are placed in the same line. Sixthly, That the drops of water, illustrated by the *Sun*, must be round, and send back the *Sun-beams* from each part of their surface, either by *Reflexion* or *Refraction*.

III. To the end we may the better conceive, how the various colours of the *Rainbow* are represented to us, we are to presuppose that we can never perceive them, but when the *Sun* shines, whose *Rays* are either reflected to our *Eyes* from the surface of some *Opake Body*, or are transmitted to us by passing through a *Body* that is partly transparent, yet ting'd with some colour or other: Or, Lastly, They reach our *Eye* by passing through some *Diaphanous Body*, wherein they have met with some *Refraction*. For no other way can be imagined for *Beams* to come to us, besides one of these three. Now because these *Beams* which proceed to our *Eye*, from a *Dewy Cloud*, cannot be said to be reflected from an *Opake Body*, seeing it is not at all probable that any such can be so suddenly form'd in the *Air*: or any *Body* that is in some sort *Transparent*, but yet coloured, to send back the *Rays* of *Light* to us in such a manner as is necessary for us to see the appearance of a *Rainbow*: and that we find by experience, that when a *Rainbow* appears, the *Air* is full of watry or dewy Drops, which are transparent, without any colour; therefore we may with good ground conclude, that the *Rainbow* represents these colours to us, only by the mode or manner of the *Sun-beams* acting upon the Drops, they pass through, and so suffering some *Refraction*.

IV. This may be confirm'd by many Examples, as by water spouted out by *FULLERS* when they bedew and moisten their *Cloath*. In those *Bubbles* which *Children* make by dipping a *Straw* or other small *Pipe* in a *Lather* of *Soap* and *Water*. And in *Artificial Fountains* that cast up *Water* to a great height, which being there dispers'd in the *Air* do exhibit the form of a *Rainbow* on these scatter'd drops, illustrated by the *Sun*.

V. The chiefest colours are *Scarlet* or *Crimson Red*, which is seen in the utmost part of it; next to which is *Yellow*, the third *Green*, and the inmost *Purple* or *Violet* colour, or as others will have it *Blew*. I said that these are the chiefest colours, because by the mixture, passage and termination of these, many other colours arise. The foresaid colours are chiefly seen in the *Primary Rainbow*, which many times appears alone. But in the *Secondary Rainbow*, which is higher and more large than it, these colours are weaker, and turn'd the contrary way: for in it the *Purple* is the utmost colour, the next *Green*, the third *Yellow*, and the lowest deep *Scarlet*. And the same thing happens in a *Prism*, according as the same is beheld upwards or

downwards, for accordingly the order of those colours appears inverted to us.

As to the cause of these various colours that appear in the *Rainbow*, it will be sufficient for us to know that *Light* is nothing else but a certain action or motion of a subtil matter, whose particles, like so many *Globuli* or round *Pellets*, are conceived to rout through the *Pores* of *Earthly Bodies*; which *Globuli*, according to the variety of the *Causes*, which determin their *Actions* or *Motions*, are diversly moved. So that if we suppose them to be so determined, that they whirl round with a greater force, than they move according to a *Right Line*, they produce a *Deep Red Colour*: if they be not whirl'd about altogether so strongly they imprint the sensation of a *Yellow*. And on the contrary, if they be not whirl'd about so fast, as used to be at other times, when there is no such Cause to resist their motion, they produce a *Green* colour; and a *Blew* when they are mov'd much more slowly.

How these Colours are produced, we shall easily apprehend, by expoling a *Globe* of *Glass* B C D, to the *Sun*; for then we shall see, supposing the *Sun* to shine in the part of *Heaven* A F Z, and the *Eye* placed in the point E, that the part D, of the *Bottle* or *Globe* of *Glass*, will be ting'd with a deep red colour. And that whether we bring it nearer, or remove it farther from us, the same colour will still appear to us, provided we keep the same station; and that the line D E, with the other E M, which we are to conceive drawn from the *Center* of the *Eye*, to the *Center* of the *Sun*, do constitute an *Angle* of about 42 degrees, for then the part D will be equally coloured *Red*. But if we should dilate this *Angle* a little, this *Redness* will disappear; and if we contract the said *Angle*, then will it not altogether vanish, but will first be divided into two parts less bright, in the which *Blew*, *Yellow* and other colours will appear. Afterwards if we proceed and view the part of the *Glass Bottle* K, we shall observe, by making the *Angle* K E M, of about 52 degrees, that the said part K, will be likewise ting'd *Red*; but not so bright and lustrous as that of D; and that upon dilating the said *Angle*, as before, other colours will appear, but more weak and fading; and that upon our contracting the same, or by dilating the same much wider, they will wholly vanish.

From which instance we are plainly inform'd, that the whole space of the *Air* to M, being filled with such *Glass Globes*, or which is equivalent in this case, with drops of *Water*, some point of them must be ting'd with a *Red* colour; from whence the lines drawn to the *Eye* E, will with the line E M, constitute a line of about 42 degrees, such as we suppose these to be that are marked by the Letter R; and that these points considered altogether, without observing the place wherein they are, save by the *Angle* under which they are beheld, will appear like a continuous *Circle* of a *Red* colour; and so likewise that there must be some points in those Drops, which are at S and T, from whence lines drawn to E, will constitute somewhat more acute *Angles* with E M, by which the *Circles* of the more weak and fading colours are composed. And that in this the *Primary* or *Inward Rainbow* doth consist. Then supposing the *Angle* M E X, to be of 52 degrees, that a *Red Circle* must appear in

VI. What is the Cause of the Colours in the Rainbow.

VII. How these various Colours do appear in the Rainbow.

Figure 56.

in the Drops at X, and other Circles of a less deep colour, in the Drops at Y; and that in this the Secondary or outward Rainbow doth consist. And lastly, that by all the other drops marked V, no colours at all are produced.

VIII. A Primary Rainbow therefore is produced by those Rays which come to the Eye after 2 Refractions, and one Reflexion; whereas the Secondary is generated of the Solar-beams, reaching the Eye, after 2 Refractions and 2 Reflexions. For if we make a more accurate search whence the Red colour proceeds, which appears in the part D, of the Round Glass, we shall find that it depends on the Sun beams (which we look upon as so many parallel lines, because of the vast distance of the Sun from us) which coming from A, to B, entering the water, are refracted in the point B, and go on to C, whence being reflected to D, and there coming out of the water, and a second time refracted tend to E. For as soon as any Opaque Body shall be opposed to any of the Lines A B, B C, C D, or D E, immediately the Red colour will disappear; and tho' we should darken the whole Ball of Glass, excepting only the 2 points B and D, and should round about beset it with Opaque Bodies, provided nothing do hinder the Action of the Rays A B C D, yet the same will shine brightly. Afterwards having in the same manner searched out the Cause of the Red colour appearing in K, we shall find that the same depends on the Solar Beams, which coming from F to G, are there refracted towards H, and in H, reflected to I, and again from I, reflected to K; and lastly being again refracted in the point K, tend towards E. And therefore a Primary Rainbow is represented in a Dewy Cloud, or in the several drops opposit to the Sun, after 2 Refractions and 1 Reflexion; but the Secondary after 2 Refractions, and as many Reflexions.

IX. If any object that Rainbows sometimes appear in those places where there falls no Rain at all; and therefore they do not always proceed from those Causes we have here assigned to them. I answer that a Rainbow is ever represented in Rainy Drops, and that they never appear but in rainy weather; for the Rainbow is an individual companion of Falling Rain, tho' possibly it may not rain in that place from whence the Rainbow is seen, yet sure it is that it must rain in that place where it appears.

X. Tho' a Rainbow be visible to all, yet it is not seen by all after the same manner. For seeing that the Drops which appear stain'd with some colour, are perceived about the Axis Visorius, under a certain Angle, and that all Spectators have a different Axis, it follows that every one of them must have his peculiar Rainbow. Yea, if the same person chance to go back, or forward, only some few steps, he will not behold the same, but still a different Rainbow; seeing that the Drops of Water, are for example, represented under a certain Angle of Refraction, as the said Angle is enlarged by going forwards, or diminished by going backwards, the Rays of Light will be variously returned, and will make a different Rainbow. So that there are as many Rainbows, as there are places, from whence they are beheld; wherefore it is no wonder what the Proverb saith, that the Rainbow flies from those that follow it, and follows those that flee from it.

XI. HALOS, or the Circles which appear about the Sun and Moon, are much of the same nature with the Rainbow. For they are round like the Rainbow, or approach to it, and have always some Star for their Center; for how swift soever the Stars motion may be, it is always found in the Center; which is a manifest Argument, that these conspicuous Circles or Crowns are produced by Reflexion or Refraction. They agree also with the Rainbow in this, that they are of various colours like it; whence we must conclude that Refraction, and a shadow that may terminate the Light, are necessary to the Production of these Circles.

Yet these Circles differ also from a Rainbow, because a Rainbow is never seen but in rainy weather, tho' it be not necessary that it should always rain where the Spectator is. Whereas these never appear in rainy weather, which is a plain argument that they are not generated by Refraction made in the drops of water, but by that which is made in the particles of Ice, found in the figure of Stars; for we cannot meet with any other Cause to which we may ascribe this effect.

When therefore at any time there be Clouds in the Air, of a moderate thickness, the Light of the Sun or Moon, piercing the little particles of Ice, whereof they are composed, becomes refracted in such a manner, that not being visible save only to a certain distance from those Stars, it produceth the appearance of several colours, viz. Red on the shady side, and Blew or Purple on the side toward the Sun or Moon.

As for example, when the Beams, proceeding from the Sun or Moon A B C, darting against a Heap of Icy Stars G E F, lying upon one another, are refracted, and reach the Eye of the Spectator D. For if the Beam proceeding from the point A, to the end of the Icy Star G, and the Ray from the point C, to the end of the little Star F, be refracted towards D, it is plain, that besides the Beams A D, and C D, and such like, which passing in a right line, do represent the Sun or Moon in their proper form; others being refracted in E E, will make the Air comprehended in this Circle F F, very Bright, and represent its circumference betwixt the Circles F F, and G G, in the form of a Crown or Circle distinguish'd with the colours of the Rainbow. So as that the Red colour will appear on the inside about F, and a Blew colour on the outside at G.

There are likewise other CIRCLES formed in the Clouds, but very different from those we have now mentioned; because they appear only of a White colour, nor have they any Star in their Center, as the Circles or Halos have; but for the most part pass through the Centers of the Sun or Moon, and seem to be altogether, or almost parallel to the Horizon. And these are only seen in Great and Round Clouds, covered with Ice, in which Mock-Suns are represented by means of Reflexion or Refraction. For the Sun darting its Beams against a Snowy Cloud that is covered with Ice, and from the Ice reflecting into the Snow, must represent the same to the Eyes of the Spectators standing on the Earth under it, in the form of a great Circle. Hence it is that these PARHELIA are called Mock-Suns, because they are reflected re-

What Halos are, and wherein they agree with the Rainbow.

Dedicated by Richard Blome

presentations of the true Sun in a Cloud, as Images in a Looking Glass.

XVI. In such a Circle as this, there sometimes appear 2 Suns, sometimes 4, yea and sometimes 6. For let D E F G H I, be a great and round Cloud, the upper part whereof D E F, we suppose to be thicker, as being more exposed to the Wind and the Heat of the Sun. The Sun being sufficiently High to the South A, and the Eye of the Spectator K, 6 Suns may appear in this Circle: The first and chiefest at E, by Beams proceeding from the Sun A, at right lines: the second and third at D and F, by refracted Beams, that penetrate the Ice in those places; where its thickness decreasing by degrees, they are on both sides crooked or bent inwards. Whence it is that these two Suns cast a Red Colour towards their Circumference, on that side where they look towards E, where the Ice is thicker; and a Blew Colour on the other side, where it is more thin. The fourth at H, is seen by directly reflected Rays: And lastly, the fifth and sixth G and I, by Rays reflected to equal Angles.

XVII. But in case the Spectator be not at K, but somewhere nearer to the point B, so as that the Circle, whose Center is supposed in his Eye, and to pass through B, do not cut the Circumference of the Cloud; then will not he be able to see the 2 Suns G and I, but only the other 4. And if on the contrary he go back much to H, or somewhat further to C, he will see 5 only, viz. D E F G and I, and removing much more backwards, he will see 3 only, and those 2 not contained within a white Circle, but as it were pierced with a white Cloud.

XVIII. When such a like Image is beheld under the Moon it is called PARASELENE, that is, a Mock-Moon, which admits of a like application with that of the Mock-Suns already spoken of; for as a Mock-Sun is the Image of the Sun reflected in a Cloud; so is a Mock-Moon an Image of the Moon appearing in a Cloud. Such were those which appeared in the year 1671, the 25th of May about 11 a Clock at Night, when the Moon was very much declined towards the South, and near the Horizon.

CHAP. XXI.

Of Fire.

I. FIRE is a Company of Particles of the Third Element, moved with the most rapid motion imaginable. Or, it is a Lucid and Fluid Body, consisting of Earthly Particles, most swiftly moved by the matter of the First Element, upon which they swim, as it were.

II. Fire is said to be hot, by reason of the various agitation of its Particles, whereby they are most rapidly agitated every way. It is said to be Lucid or shining, because the subtil matter, which agitates the Terrestrial Particles, is whirled round, whence whilst it endeavours to recede or withdraw itself, it presseth the Heavenly Globuli, in which pression Light consists.

III. Nevertheless every Fire is not Hot and Shining; for there is one sort of Fire which is only shining, as in Rotten Wood and Glow-worms; and another sort which is hot only, as in Dung, and a third sort that is both hot and shining together.

Fire is only shining when the most subtil matter of the First Element running this way and that way in the strait pores of Earthly Bodies, which resist the entrance of any other matter, doth push forwards the Heavenly Globuli: or else when the said matter is in so small a quantity, that it can only press the Celestial Globuli, which of their own nature are sufficiently incited to Motion, without being able to agitate the Terrestrial Particles. Again, the Fire will be only hot, when the subtil matter is in such abundance, that it can also agitate those Earthly Particles, but yet withal is so entangled with the Earthly and Watry Particles, that it cannot explicate itself, nor push forwards the Heavenly Globuli every way, in a right line. And lastly, Fire is both shining and hot, when it is so at liberty as both to be able to press the Heavenly Globuli, and most swiftly to move the Terrestrial Particles.

Violent Motions are very proper to produce this effect, because the Earthly Particles, to which they communicate themselves, tho' they be at first encompassed with the Second Element, yet they move fast enough to drive them away from about themselves, and to admit nothing but the First Element, which much augmenting their agitation, doth dispose them soon to separate themselves from one another, and to take upon them the form of a Flame.

In order therefore to the kindling of Fire, that is, to the gathering such store of the matter of the First Element, as may both shine and burn, it is necessary that the Globuli be driven out of the Intervals of some Terrestrial Particles, which being afterwards separated from each other, and only swimming in the matter of the First Element, may be snatched away with its most swift motion, and driven every way. That this is so, we shall easily conceive, if we consider that the matter of the First Element doth in swiftness much exceed that of the Second Element, and that those little Bodies which swim amongst the particles of these 2 Elements, can only be carried along by the motion of the Second Element, for that its Globuli do break the force of the First Element, and resist its motion: whereas on the contrary, whilst those Earthly Bodies are surrounded with the matter of the First Element, they must necessarily comply with its agitation, in like manner as we see that a piece of wood is carried away by the swiftness of the stream wherein it swims.

Thus we find that the Brightness of a Flame is greater, and more conspicuous in a dark Place, than in one enlightened by the Sun; because in a place so illustrated, many Globuli of the Second Element from the Sun, are sent into the Flame, which lessen the agitation of the matter of the First Element, and consequently also the violence of the Fire. Whence also it is that when our Optick Nerve is strongly affected by the Fulgid Light of the Sun, the light of a Candle, compared with that of the Sun, seems to be none at all, as being scarcely discernable by our Eyes.

From what hath been said, we may gather the chief Qualities of Fire: for seeing that its particles are solid, and most swiftly moved, they cannot but produce heat, which, as shall be said in the following Chapter, is nothing else save the actual various motion of the little parts of the Body, affecting

IV. What is the Cause of these various Fires.

V. Violent Motion produceth Fire.

VI. Fire is kindled by driving out the Globuli from the Intervals of the Terrestrial Particles.

VII. Whence it is that the Brightness of a Flame is greater in a dark than in a light Place.

VIII. Why Fire is hot and shining.

the sense of feeling. And so also if together with this we call to mind, what before hath been said concerning *Light*, viz. that it consists in an endeavour of receding from the Center, or in the pressure of the *Heavenly Globuli*. For seeing that the subtil matter, that constitutes *Fire*, is constantly whirled round, and endeavours to recede thence, it cannot but procreate the sense of *Light*, and make the *Fire Bright and Shining*.

IX. *Fire may be kindled several ways: First* out of *Flints*, for they being of a hard substance, if other *stiff Bodies* dash against them, by this means the *Globuli* of the *Second Element*, because of the narrowness of the interjected space, are forced to march off, leaving only behind them the matter of the *First Element*, and so the *Earthly Particles* which swim upon it, and follow its motion produce *Fire* and are turned to *Sparks*. Which may be the Cause why we find that in *Subterraneous Places* *Fire* is often kindled. For since there is always in those places a *viscous slimy matter*, and many *exhalations* are sublimed there by the *Sun's heat*, it may so happen that one *Flint* dashing against another, may send forth *sparks*, by which the *exhalations* that cleave to the kindled *viscous* or *sulphureous matter*, may communicate a *flame* to the *Bodies* that are nearest to them. Now that there are such fat and *sulphurous Flames* in the *Bowels* of the *Earth*, is well known to the *Miners*, and Reason evinceth the same; for seeing that there is a *Fire* in the *Bowels* of the *Earth*, there must be *Fumes* arising from it; seeing also that there are *sulphurous hot Bathes*, and *veins of Jews Lime*, and other *oily matter* boiling in the hidden Channels of the *Earth*, we may easily judge that from these also a continual *Smoak* or *Fume* must proceed by way of *exhalation*. And it seems probable, that the first kindling of those *Fires* which burn in *Mount Aetna* in *Sicily*, and *Vesuvius* in *Campania*, hapned after this manner.

X. *There is also another way of kindling Fire, viz.* when the *Beams* of the *Sun* are concentrated in a *concave Glass*, for by this means the *Globuli* acting with their joint forces, do excite a various and vehement excitation of the *Terrestrial Particles*, whence proceeds a *Flame*, the *Heavenly Globuli* being beaten back, by the swift agitation of the *Terrestrial Particles*, so as that the *Particles* of the most subtil matter can freely flow together and continue this agitation.

XI. *A Fire also may be kindled by sharp Spirits*, as appears in *Hay*, which if it be laid up before it be sufficiently dry, it becomes hot by degrees, and at last breaks forth into a *Flame*, because the *Spirits* of *Herbs* that are shut up in it, have not so free an egress, as when they were *Green*, and before they began to be dried; and therefore being no longer able to enter into the same passages, with the *Globuli* of the *Second Element*, they become surrounded only by the matter of the *First Element*, which putting them into a most swift motion, makes a *Flame* to appear. But this never happens in *Wood*, tho' it be struck never so much, because its substance is not stiff enough, that by a concussion of another hard Body, the *Globuli* of the *Second Element* should be driven away, because the part that is struck bends towards another, before that the *Second* begins to bend towards the *Third*, and that again towards those that are next

to it, by which means its force of flying back is lost.

But forasmuch as *Flame* is perpetually turn'd to *Smoak*, and is no more the same than a *River*, which is continually supplied by an access of new waters, it is of absolute necessity that it have some *Food* or *Fuel* whereby it may be preserved and maintained. And this is no other but those *Terrestrial Parts*, which being agitated by the matter of the *First Element*, have a power to drive away the *Air* or any other *Body*, that might extinguish it. It is also requisite that these particles be very thin, that they may be able to supply the room of the vanishing *Smoak*: for the thicker particles are easily surrounded by the *Globuli* of the *Second Element*, and possessing themselves of the places which the particles of the *First Element* have left, do much break the force of the *Fire*, and choak its *Flame*.

For which reason also all *Oily, Sulphurous* and *Bituminous Bodies* are of all others most conducive to maintain and preserve *Fire*; for that by reason of the contexture of their *Branch-like Parts*, and their fit *Thickness*, they are most fit and disposed to be agitated by the particles of the *First Element*, and being thereby driven out of their places, to communicate their motion to other *Bodies* with such force as that they drive away the particles of the *Second Element*, which otherwise would extinguish the *Fire* into which they strive to enter on every side.

These things premis'd, it will be easie to conceive, that *Flame* is nothing else but a *Fire* wholly at liberty, that is, a *Fire* whose parts are so agitated, that they entirely separate themselves from each other, and do only swim in the matter of the *First Element*. It will be likewise readily conceived how a *Flame* is produc'd, by viewing the *Candle* A B, and reflecting that there be many parts of *Figure* Wax that move very swiftly throughout the whole space C D E, where they constitute a *Flame*, because they swim alone in the matter of the *First Element*. We must also consider, that the parts of *Wax* that constitute the *Flame* do continually strive to mount still higher, for that by reason of their great agitation they are more light than the *Air*, that surrounds them, which having been forced to descend continually, endeavours to return to its place again, and to which indeed it would return, if the new particles of *Wax* that come forth from the *Wick*, and which begin to follow the Course of the *First Element*, did not hinder it; which is confirmed by experience, which shews us that as soon as the particles of *Wax* cease to proceed thence, or tho' they do, yet have not force enough, the *Flame* ceaseth in the space C D E, and the *Air* possesseth it self of its place.

It is peculiar to *Flame* to mount upwards, and to end in a sharp point: the reason whereof is, because the *Flame*, by reason of the great abundance of the matter of the *First Element* that is in it, being lighter than the *Air* that surrounds it, must of necessity tend upwards: and because the middle parts of the *Flame* G D E, are more strongly agitated by means of their greater solidity, than those which are about the utmost parts C C, whose motion is much diminished by the neighbouring *Air*, this makes the *Flame* to end in a point, and its *Smoak* to break forth chiefly at the top H, where the

the *Terrestrial particles* begin to lose their agitation. As for Example, When the *Smoak* ascends towards H, it makes the *Air* to descend by I and K, towards B, where razing the *Wick*, it pushes the *particles* of *Wax* towards the *flame*, which serve to nourish it: Which Circular motion of the *Air* towards the *flame*, Experience shews us, in that when a *Chamber* is close shut, save only some little Hole or Chink, and a *Fire* be kindled in it, a *Wind* is perceived to enter in by the said Chink; and which is so much the stronger, by how much the *Fire* is greater.

upon Earth-
ly Bodies.

Fire is extremely *active*, and exerts its Force upon the *hardest Bodies*; for its *Particles*, as so many sharp *Needles* penetrate their *Pores*, and driving out the *particles* therein contained, they divide its *parts*, and turn them into their own Matter; and in case the *particles* of the *Bodies*, the *Fire* acts upon, are easily separable, then they melt. For to be melted, or in a *liquid* form, imports nothing else, but that the *Body* in that state consists of *Particles* that are divided from each other, and in some agitation. As on the other hand, *Bodies* are *dried*, when by approaching to the *fire*, their thin and slippery *Particles* are exhaled, the more thick *Parts* being left, which being thereby more closely joyn'd together, constitute *hard Bodies*.

XVII.
The Ventila-
tion of
the Air is
necessary, to
the preser-
vation of
Fire.

The *Ventilation* of the *Air* is necessary to *Fire*; because the *Air* being push'd upwards by the mounting *flame*, cannot enter into another place, which the *Fire*, by consuming its *Fuel*, leaves open for it; and whilst it thus succeeds, it like a *Fan* or *Bellows*, drives the *fire* into the more inward parts of the *fuel*, and dissipating those that are more *Heavy*, doth thus by blowing preserve the *fire*: For where this is not, and the *Air* is hindered from supplying the said place, the *flame* not being able to give way, becomes choak'd by the more *heavy* and gross *Fumes*.

XVIII.
Fire is ex-
tinguish'd
by any Li-
quor poured
upon it.

Fire is put out, when any *liquor* or *moisture* is poured upon it in a greater quantity, than can be put into motion by the force of the *fired Particles*; which is the Cause why a little *Water* increaseth the *Fire*, whereas a great deal of it doth put it out.

XIX.
Why the
Air must
have free
access into
a Chamber,
that the
Fire may
not fill it
with
Smoak.

Hence it is, that when a *Fire* is kindled in a *Chamber*, if the *Air* hath no free access to it, the whole *Chamber* becomes presently fill'd with *Smoak*. Because the *Air* drives away from it great store of *Air*, together with the *Particles*, of combustible *Bodies*: For it is these that being mix'd with the *Air*, constitute the *Smoak*, as the more solid *Parts* of those *Bodies* are turn'd to *Ashes*. And since it is repugnant that there should be any *Vacuum* in Nature, it is necessary that so much *Air* enter the *Chamber*, as there is *Smoak* going out: For except this be, the whole *Chamber* will be fill'd with *Smoak*.

C H A P. XXII.

Of the Nature of Heat and Cold.

I.
Heat and
Cold do not
belong to
any Species
of Quality

HAVING already rejected all *Qualities* really distinct from their *Subjects*, we shall not trouble our selves with the enquiry, to what Species of these *Qualities*, *Heat* and *Cold* do belong. And the rather, because these *Forms* are unknown to us; and

if we should admit them, the Enquiry will still remain, by what *Virtue* they operate, if they be *Active*; and how the *Sense* suffers by them, if they be *Passible*. Wherefore it remains only for us to determine, to what *General Head* of things *Heat* and *Cold* do belong; viz. Whether they be *Substances*, or are only to be accounted amongst the *Modes* of *Substances*.

Qualities that belong to Matter are nothing else, but certain dispositions in the *Subjects*, consisting in *Magnitude*, *Figure*, *Motion* and *Situation* of *Parts*, whence they produce several ways of Sensation: Tho' there be nothing in these *Bodies* like to those *Idea's* they awake or excite in us; so that tho' the *Particles*, for Example, of an *Hot Object* be otherwise dispos'd than those of a *Cold*, yet in neither of them is there any thing like to those *Idea's* or *Modes* of Sensation they stir up in us.

If any one therefore enquire, whether these *Qualities* are *Modes* existing in *Bodies*? We Answer that they are so, if they be taken for the various disposition of *Parts*; but not so, if they be taken for those *Modes* of Perception which they excite in us.

Heat therefore is a *Quality* arising from a greater and unequal Motion of the *Terrestrial Particles*: And *Cold* is a *Quality* proceeding from the quiet of the *Parts*, or at least from a less degree of Motion in them.

We assert therefore, That *Heat* is nothing else, but the motion or agitation of the small *Parts* of a *Body*; and *Cold*, their rest or consistence. Now that *Heat* is nothing else, but motion, may be proved from its Increase and Decrease; for we find that *Liquid Bodies* become hot, when their *Particles* are put in motion by *Fire*. Thus we find that *boiling Water*, melted *Metals*, and all other things, when set on fire, are very much agitated, neither is *heat* to be perceived in them, till their *Parts* be put in motion. In consistent or compact *Bodies* we likewise find, that when they are struck or rub one against the other, provided it be done with some Force, (as when two pieces of *Wood* are rub'd against each other, or a *Knife* whetted upon a *Whetstone*) heat is excited in them both. For the *Heat* in any *Body* becomes increased, and grows stronger, by how much the agitation is greater. Hence it is, that nothing, amongst *Natural Bodies*, is more hot than *Flame* is, because nothing hath its *Parts* more agitated, as daily Experience teacheth. And if there appear any difference between one *Flame* and another, that proceeds only, because the *Parts* whereof they are composed, are more or less thick; and consequently more or less powerful to agitate those *Bodies*, on which they exert their Forces.

When we say, That *Heat* is Motion; we are not so to be understood, as if the whole *Body* that is heated were agitated: For it is repugnant that the same *Body*, should at one and the same time be moved by various Motions; but only that the small particles thereof be in motion and variously agitated; that is, that they change their situation, and are differently apply'd to the different parts of ambient *Bodies*; so as to be tossed with various determinations, to the Right, to the Left, Upwards, Downwards, Forwards and Backwards, according to their several dispositions and figures.

really dis-
tinct from
the Subject

Wherein
the Nature
of Quali-
ties in ge-
neral does
consist.

III.
Qualities
are certain
Modes in
Bodies.

IV.
What Heat
and Cold
is.

V.
Heat con-
sists in
Motion,
and Cold
in Rest.

VI.
All the
Particles
of Fire are
moved, but
not the
whole Fire
itself.

VII.
In what
sense Li-
quid Bo-
dies are
said to be
hot.

If any one Object, That according to this Explan-
cation it will follow, that all *Liquid Bodies*, as *Water*,
Wind, *Air*, and the like, are *hot*; because, as hath
been said in our *General Physicks*, their *parts* are
variously moved. For *Water* is no other ways
distinguish'd from *Ice*, but because its *parts* are in
continual *motion*; whereas those of *Ice* continue
always in the same situation.

VIII.
The An-
swer to the
foregoing
Objection.

Before I come to give a satisfactory Answer to
this Difficulty, I would have it noted, that every
agitation cannot be called *Heat*, but that only
which is of force enough to affect the Sense of
Feeling, and to shake the *Filaments* of our *Nerves*.
For if the *motion* be not strong enough to produce
this effect, we cannot give it the Name of *Heat*;
that being an *Appellation*, which is attributed to
things with relation to our *Senses*. Thus when a
Sound is so weak, as not to reach our *Ears*, tho'
it may wave the *Air*, it cannot be called a *Sound*.
And so to denominate any thing *hot*, it is requisite
that there be such a *motion* of the *Particles*, as to
affect the *Nerves* of our *Hand*, or some other
part of our *Body*. *Fluid Bodies* therefore, con-
sider'd in themselves, and without any respect to
our *Senses*, may be called *Hot*, tho' not *compara-*
tively, that is, with reference to our Sense of
Feeling; except it should happen, that the *Par-*
ticles of our *Hand*, which is the ordinary *Organ*
of *Feeling*, be more slowly moved than the *Par-*
ticles of the *Body* that is felt: As it happens, when
with a *hot Hand* we touch a *Body* that is *Luke-*
warm, which then feels *cold* to us; and yet we
shall feel the same *Body* *hot*, if we apply our
other *Hand* that is *cold*. *Water* therefore abso-
lutely consider'd, may be said to be *hot*, because it
contains some *heat* in it self, and is capable of
being more *cold* by many degrees, as when it be-
gins to *freeze*: But with regard to our Sense it is
cold, because it excites no such Sensation as we
call *Heat*, in our *Organs*.

IX.
The Nature
of Cold
consists in
Rest.

Having discover'd the Nature of *Heat*, we
cannot be ignorant of that of *Cold*: For as *Heat*
is the various agitation of the insensible *parts* of a
Body; so *Cold* is their *Rest*, or at least a diminu-
tion of their *Motion*. For we find by daily Ex-
perience, that *Hot-water* grows by so much the
colder, as the Agitation of its *parts* ceaseth, till
at last, by a total Cessation thereof, it be changed
into *Ice*, which of all others is the most *cold Body*.
Thus the things that are said to be *cold*, are en-
dued with little or no Agitation, and consequently
are not able to move our *Senses*, but rather mode-
rate and put a stop to the *motion* of our *Animal*
Spirits. Thus, as long as our *Fingers* are warm,
we can do any thing with them; but when once
they are seiz'd with *cold*, they become useless to us
in the performing of any work.

X.
Why hot
things
take up
more place,
than such
as are
cold.

A *Hot thing* therefore differs from a *Cold thing*,
as a thing that is at rest or less moved, differs from
that which is *moved*, or more swiftly moved.
Whence it is that those *Bodies*, whose *Parts* are
agitated by *heat*, contrary to their Custom, cannot
be comprehended in so small a space or room, as
those which are at rest, or are less moved; foras-
much as by means of this *motion* their small *par-*
ticles are rendred *irregular*, which therefore require
more room, than when they are united, and are
not separated by any agitation.

Some suppose *Cold* to be nothing else, but a
Privation of *Heat*; but these seem not to have
understood the Nature of *Rest*; which is nothing
else, but an *abode in the same situation*: Now
Abode or Continuance, is something *Positive*, yea,
more *positive* than *motion* it self. For that which
is unchangeable, must without doubt more partake
of the Nature of an *Entity*, than that which con-
sists in continual Change and Vicissitude. Where-
fore we must conclude, that *Rest* or *Quiet* is a
positive thing, as having no less efficacy than
Motion. For which of the two shall we reckon
to be most positive; that which keeps together
and preserves other *Bodies*, or that which dissipates
and destroys them? Now it is the Property of
Rest to preserve many things, that by *Motion* are
spoil'd and damnified: Wherefore *Rest* ought to
be look'd upon as being more positive than *Motion*.
For who will assert, that to *abide in a place*, to
continue in time, to *rest in a Seat*, or the like,
which belong to *Rest*, to be less positive, than to
take a Journey, to *run a Race*, or to *be in a con-*
tinual flowing, which belong to *Motion*? Indeed
it is an Error of our Mind, whereby we take *Rest*
to be something *Privative*, and *Motion* to be *Pos-*
itive; because we experience, that the one depends
on our *Will*, whereas the other is scarcely taken
notice of by us.

It seems strange to some, that by *Rest* only,
which constitutes the Nature of *Cold*, *Rivers* and
Seas should be *frozen*, and the Life of *Animals*
should be destroy'd: And yet it is evident, that all
this is done by *Rest* alone, not the least of *Motion*
being to be found in any of these Effects. For
what doth the *freezing* of *Rivers* and *Seas* import,
but such a union and clinging together of their
parts, whereby they do consist and are at rest?
For no stronger *Argument* can be alledg'd to
prove, that any *Bodies* are joyn'd, than to say that
they lye at rest together.

For tho' a whole *Body* of *Ice* may be carried
along the *Water*, yet its *Parts* notwithstanding
are at Rest together; for in case they were in
agitation, then would they no longer constitute *Ice*,
but *Water*; as we find, that when the *Frost* breaks,
the *parts* of the *Ice* that lay still together before,
by being separated through *motion*, turn to
Water.

That *Cold* is the Cause of the Death of *Living*
Creatures, must not seem strange to us, seeing that
our *Bodily Life* consists in the various agitation of
the *Blood*, *Spirits* and *Humours*, upon the diminu-
tion or cessation whereof, *Life* it self must cease
also. For as by too intense *Cold*, that is, by the
consistence of the insensible *Particles* of the *Air*
and *Water*, the *Water* that turns a *Mill* is con-
gealed; so the total cessation or diminution of the
motion of the *Blood* and *Spirits* in the *Bodies* of
Living Creatures, deprives them of *Life*. As we
find, that in the *Winter* time, *Flies* and many other
Living Creatures consume and *dye*, especially when
the *cold* is very intense.

As there is an *Actual Heat* and *Cold* found in
Bodies, so some *Bodies* are said to be *Potentially*
hot or *cold*. Those are called *Potentially hot*,
which have an aptitude or disposition to grow *hot*,
or *heat* other things; which ariseth from hence,
that their *particles* are so disposed, that they are
liable to be more violently moved by the *Subtil*
matter,

What Po-
tential
Heat and
Cold is.

matter, which runs through all Bodies. Thus Quick-Lime, which is cold to the Touch, is said to be hot Potentially, because the Subtil matter can easily excite an Agitation in its Pores. In like manner all other Bodies, which can produce such a motion in the Particles of other Bodies, are said to be Potentially hot; such as are Pepper, Ginger, Spirit of Wine, and the like. And on the contrary, that Body is said to be Potentially cold, whose Particles cannot be agitated by the Subtil matter; or whose disposition of parts is such, as to hinder the particles of any Body to be put in agitation by others; such as are Lettice, Vinegar, &c.

CHAP. XXIII.

Of the various Effects of Fire.

I. Some Effects of Fire remain still to be explained.

Having hitherto consider'd the Nature of Fire, and how it diffuseth Light from it self through the Air, and communicates heat to those Bodies that are near it; it remains now that we explain some other of its Effects, viz. how it rarefies and condenses some Bodies, softens and melts others, and again hardens and dries; changeth some into Calx or Ashes, and others into Glass. In order to the giving of a Reason for these different Effects, we are to presuppose that Rule of the Philosophers; that Every Action is received, not so much according to the manner and condition of the Agent, as according to the Disposition of the Patient. The Action of the Fire is every where one and the same; but the difference of the Effect proceeds from the diversity of the Matter whereon it acts.

II. How the Fire rarefies Bodies.

In the First place therefore, if a Body, whose Parts are pretty close together, be very much heated, let those parts be of what figure they please, provided only that they be not Round, whilst they are whirl'd about their own Center, they cannot but meet with their Corners, and push one another, and then such a Body is said to be rarefied; as appears in Milk, when it boils, as well as in other Liquors. The same may be often perceived in hard Bodies, which being heated, do lose few of their Particles by Exhalation. Thus Red-hot Iron is more turgid than that which is cold.

III. How it condenses them.

But in case the Parts of a Body be very light, and very susceptible of Agitation, and yet have some slight Coherence; yet so, as that they scarcely touch one another, and constitute a Whole, that is, of a very loose and incompact Substance, the least heat supervening to such Bodies as these, and communicating some motion to their parts, disposeth them to a nearer Conjunction, and by this means condenses the whole Body: As when Heat reduceth Snow to a less bulk, by making the parts of it closer together.

IV. How Bodies grow soft by the force of the Fire.

The Fire softens Bodies, by agitating their Particles with so moderate a Motion, as doth only move them, without separating them from one another. Which happens only in those Bodies that consist of such parts, as are with equal facility separated from each other; as in Wax, a hot Hand, Lead, and other such like, whose insensible parts are not wholly without motion, tho' the slowness of it make it imperceptible.

The Fire melts Bodies, whilst it not only moves their Particles, but also separates them from each other, as to their situation. For by the violent agitation of the Fire, the particles of Bodies are separated from one another, and most swiftly moved. And accordingly Metals, tho' otherwise hard Bodies, are by the force of Heat melted, and resolved into Homogeneous Particles, as they are usually called.

A like Effect of Fire is DISTILLATION, by means whereof a Body is changed first into Vapour, and afterward, as that Vapour condenseth, is turn'd to Liquor: Which may be done several ways, according to the several degrees of Fire, as by the moist Heat, as the Chymists call it, which is that of a Balneum, or by the dry heat of Ashes, Sand, or a naked Fire. And by this separation of parts, there are distill'd from Bodies first Burning Spirits; then Phlegm or insipid Water; and lastly, a sharp and corroding Liquor, which by a very violent Fire is distill'd from Salts.

But if the agitation of the Liquid particles be so great, that some of them be carried upwards, or be changed into Air or Fire, and so requiring a greater Space wherein to dilate themselves, and to pursue their motion, do thrust other Bodies out of their places; then these Liquid Bodies become very hot and boil. Now this great Heat or effervescence is carried on with an equal motion, and without any great perturbation of their parts, when the said Liquid Bodies do not contain much Heterogeneous matter; as it happens in Wine and pure Water. But they boil, where the Matter of Bodies is more Heterogeneous, partly spirituous and volatile, and partly thick and clammy, or ropy: These being the two Matters that concur to the making of Bubbles; for viscons and clammy Matter serves to make the Skins of the Bubbles, and the volatile Matter furnisheth that Aery Spirit that fills and diffends them. But if the agitation of the Heat be not strong enough to overcome the Heaviness of Bodies, then it cannot dilate those Bodies, so as to make them take up a greater Space. And therefore it is, that the particles of Metals do not fly up into the Air, because the force of Heaviness that is in them, surpasseth the Activity of the Fire.

As the Fire softens and melts some Bodies, so it hardens and dries others, viz. such as are compounded partly of thin, flexible, slippery and volatile Parts; and partly of Thick and Branchy parts mix'd together, but not very firmly sticking to one another. For that Body is said to be dry, which wants those fluid Particles, which when united together do constitute Water, or any other Liquor. Such Bodies as these therefore, as soon as they come near the fire, their fluid and thin Particles being exhaled or turned into Vapour, become dry, and their thick and branchy Particles are left alone by themselves; which being more nearly and closely joyned, and with greater firmness hanging together, do constitute hard Bodies. As is manifest in Clay, some of the pores whereof are by heat shut up, and others again dilated and left more open.

Another Effect of Fire is, that it separates most Bodies either into a kind of Calx, or into Ashes, according to the various application thereof. For when those Bodies that are apt to melt, are so

M m m

V. How Bodies are melted by the Fire.

VI. How Bodies by Fire are resolved into Vapour, and afterward turn to Water, or other Liquor.

VII. How Bodies come to heat and boil, by means of Fire.

VIII. How it comes to pass, that the Fire hardens and dries some Bodies.

IX. How Fire turns Bodies into a Calx and placed Ashes.

placed, as that a violent flame of Reverberation may beat upon them, they become turned into a Calx. For all Hard Bodies, which by the Action of Fire, are reduc'd to a powder, by expulsion of some of their thinner Particles, which joyned the other parts together, are said by the Chymists to be turned into a Calx. So that Calcination is an Operation, whereby a mixed Body, especially Stones and Metals, are reduced into a small Powder. Neither is there any other difference between Ashes and a Calx, save that Ashes are the Remainers of those Bodies, whereof a great part hath already been consumed in the fire; Whereas a Calx is of those Bodies, which suffer little or no diminution at all by the Action of fire, as not being inflammable. And both of them agree in this, that they consist of solid and thick Parts, such as by the ordinary force of the fire cannot be changed into Vapours, and are of irregular and many Corner'd figures; so that they only lye upon one another, without sticking close together, and probably do not touch one another, but in some very small Points.

X. If afterwards these Calces, or the Ashes, are committed to a strong and long continued Fire, their Corners or Angles, which are the cause of the Roughness and Opacity that is in Ashes, become bended, by which means the particles being agitated and tost together, are at last more closely joyned, polished, and made more smooth, which touching each other only, according to little Surfaces, do constitute that hard, transparent and brittle Body, which is commonly called Glass.

XI. GLASS is a hard and stiff Body, because it consists of thick and inflexible particles, which are not joyn'd together by any intangling of the Branchy parts, but by contact only. It is Transparent, because after its concretion or coagulation it still retains its Pores, through which the Heavenly Globuli can continue their motion to Right Lines, according as they were moved before, when it was Liquid. Lastly, It is Brittle, because the Surfaces, in which its particles touch one another are very small.

XII. Fire not only exerts its Activity upon the Surface of the Earth, but also in the Cavities or Inward parts of it; where it is the cause of EARTHQUAKES, as often as any great store of Exhalations are found there: Not that they of themselves are able to produce this effect, seeing their Particles do only constitute the Air; but because they easily mingle themselves with the more Subtil particles of Spirits, and being heated and kindled by them, seek for a larger place wherein they may dilate themselves; and being not able to find that, they shake all that stands in their way: Much in the same manner as Gunpowder, shut up in a Mine, as soon as it is kindled, by endeavouring to make room for it self, makes a great Confusion, making the Earth to quake. Which is the reason why those places are most subject to Earthquakes, which abound with Veins of Saltpetre, Brimstone, or other Oleaginous matters; these being easily kindled by Spirits, or by any spark of Fire, from the dashing together of Stones or Flints. And as soon as they are kindled, not being able to contain themselves in the same Space, they are carried upward, and break

through their Prison Walls, to make room for themselves.

EXHALATIONS, kindled in the Holes of the Earth, do break forth outwardly on the Surface of it, when they are of force enough to make a way for themselves thro' the outward Crust of the Earth; but when they are not of strength enough to do this, they only cause a simple Earthquake, that is, they only make the Country round about to rise a little; as Gunpowder raiseth the Terrasses that lead to the Mines. An Earthquake therefore is nothing else, but the Shaking of any Place or Country, which is accompanied sometimes with a breach of the Ground, and a terrible Noise.

FERMENTATION is accounted amongst the Effects of Fire; and happens, when the Matter of the first Element is so shut up in the narrow Pores of Earthly Bodies, that tho' many thick Particles swim in their little Spaces, yet are they so agitated by some Watry and Airy particles that are insensibly mix'd with them, as to be able to affect our Nerves, and produce the perception of Heat. Such a fervescence or rising is found in Dough, and in the working of New Wine, Beer, and other potent Liquors: So likewise in Oil of Vitriol, mix'd with Salt of Tartar; Aqua-fortis, in which Copper is put, and other such like. Because the Particles of these Bodies are so agitated by the Ethereal matter, that runs through their Pores, as not only thereby to be heated, but also rarefied and subtiliz'd; so that the Hooks and Intanglements, whereby their Particles before were held and kept together, are dissolved. Fermentation therefore is nothing else, but the adventitious and expansive Motion of the insensible Heterogeneous parts of fermenting Bodies, excited without any sensible Cause.

Bodies subject to Fermentation are not of one kind; for they may be either Animate, or without Life, Thin or Thick, Natural or Artificial, provided they do consist of Heterogeneous parts. Now this Heterogeneity of parts is found in those Bodies, which are compounded of Particles, whereof some are in continual motion, and others again are Earthly, thick, and more fix'd, which hinder the more Volatile parts from flying away. For on this contrariety and strife of the Parts fermentation chiefly depends; for where the Particles are of the same figure and conformation, no fermentation can be excited. Thus we find, that New Beer, or Wine, when shut up in narrow Mouth'd Bottles do ferment or work with such Violence, that they often break the Bottles: Whereas if the parts of these Liquors be separated by distillation, they will no longer be capable of fermentation. For which Reason, Stillaritious Oils, burning Spirits, and distill'd Waters, will continue a vast while without the least change by fermentation. Thus Spirit of Wine, shut up in a Bottle, is very far from falling into a fret or effervescence; but if you add some Oil of Turpentine to it, it excites such a commotion of the parts, as endangers the breaking of the Bottle, in case it be close stop'd.

CHAP.

XIII. Subterraneous Fires act differently.

XIV. What Fermentation is, and the Cause of it.

XV. Heterogeneous Particles are required to the Motion of Fermentation.

IV. The opinion of the Peripateticks concerning mixture.

V. The Peripateticks concerning mixture.

CHAP. XXIV.

Of the Mixture of Bodies: As likewise of their Changes, Conversion, Generation, Corruption, Alteration, Augmentation and Diminution.

I. **T**HAT it may be the better apprehended what *Mixture* is, we are to observe that things may be mingled after a twofold manner; the first way is, by a *Composition* or rather *Apposition* of the things to be mingled. The second by their *Coalition* or *Confusion*.

II. Those *Bodies* are said to be mingled by *Apposition*, whose parts do not wholly mix and run through one another, but only superficially touch one another, keeping their distinct natures, as when *Fruits* of several sorts are heaped together, and make one heap. But the *Mixture* by *Coalition* or *Confusion* of *Bodies* is, when they are so mingled, as that they wholly run through one another, so that there is not the least *particle* assignable in the *mixed Bodies*, which doth not consist of every one of them. According as some think that the parts of *Water* pour'd into *Wine*, are so thoroughly mixed with the parts thereof, as to be susceptible of the same *Action* and *Passion*. This last kind of *Mixture* *ARISTOTLE* seems to defend lib. 1. de *Generat. cap. 10.* where he asserts that a new *substantial form* is produced in *Generation*, and that there is no part of the *mixed Body* so small but is mixed.

III. But this opinion of *Aristotle* is not at all probable, for if we should suppose the most perfect mixture of all the most minute parts of a *Body*, this would destroy the very nature and notion of *mixture*; since it is the common notion of *mixture*, that the things mixed must still continue; for if they do not abide, then it is not a mixture of several things, but a destruction. Besides, if the parts of a *Mixed Body*, do wholly through and through pierce one another, so as to be coextended every way, then two *Bodies* will be in the same place, seeing there is no part so small that is not mixed, and that is not partaker of all the parts both in *substance* and *quality*. From hence also it will follow, that a small *Body*, by example a *Pint* of *Water*, will be equal and coextended to a far greater *Body*, viz. a *Gallon* of *Wine*, seeing that there is no part so small, which does not consist of *Wine* and *Water*.

IV. Some *Aristoteleans*, to avoid these absurdities, tell us, that all *Miscibles* are not of the same *Power* and *Virtue*, and that the weaker do yield to the stronger. So that when a drop of *Water* is cast into a *Hogshead* of *Wine*, it produceth no mixture, but that the form of the weaker part, viz. *Water*, is by the more powerful *Wine*, changed into its own nature, so that by the addition of this drop of *Water*, the *Wine* contained in the *Hogshead* is encreased one drop.

V. But this *Evasion* doth not agree with Reason; for I will only demand of them, whether this drop of *Water* cast into the *Hogshead* be changed into *Wine*? They will say it is. But if after this first drop, another and another be put in, and this continued, till the first quantity be 2 fold, 10 fold, 100 fold, 1000 fold encreased, what will be the kind or substance of this *Liquor* then? The *Peripateticks* according to their Principles, must say that the whole *Mass* of this *Liquor* will be pure *Wine*; tho' instead of one *Gallon* of *Wine*, a 1000 of *Water* may have been pour'd into it drop by drop, since according to them, every drop of *Water*, by the overpowering quantity of *Wine*, was turned into *Wine*. But is not this absurd? If they will not own this, let them tell us when the *Wine* began to lose its form; and at what particular drop of *Water*, the whole *mass* of *Water* became deprived of its form. But here they must be silent, and tho' fore against their wills, acknowledge their Ignorance.

Wherefore rejecting this *Sentence*, we must adhere to the former, and maintain that the *Mixture* of *Bodies* is performed by the apposition of particles to each other: Thus when *Wine* and *Water* are mixed together, the parts of each *Liquor* continue in their distinct natures; so as that the particles of *Wine* and *Water* are not in the same, but in distinct places, as black and white *Threads*, in the Weaving of any *Stuff* or *Clouth* do each possess their distinct intervals. Neither must it seem contradictory to what we here assert, that the mixture of *Wine* and *Water*, cannot be perceived by our *Senses*, because the particles of *Wine* and *Water* are so small and subtil that they cannot be perceived by our *Sight*, nor distinguished by our *Taste*.

And certainly we have great reason to believe that *Mixture* is performed after this manner, since we find that *Bodies* that are mixed may be separated again from each other. Thus *Wine* that is mixed with *Water* may be separated from it, either by a *Sponge* dipt in *Oyl*, or by a *Cup* made of *Ivy*, or by extreme Cold, which freezing the *Water*, leaves the *Wine*, or at least the most *Spirituous Part* thereof in the center of the *Icy mass* unfrozen. And the same is almost perceived in every *Body*, wherein there is but a little quantity of *Sulphur* and *Spirit*; for if you distil out of *Vitriol*, *Tartar*, *Saltpeter* and the like, their *Phlegm* and *Acid Spirit*, and after distillation, put them again to the remaining dregs, which the *Chymists* call their *Caput Mort*, you will find the same *Body* restored, which was before distillation, and almost of the same quantity or bigness as it was before. *Chymists* observe that when they mix the *Spirit* of *Vitriol* with the *Salt* of *Tartar*, there at first happens a great effervescence or ebullition, and when that is over, both the *Liquor* and *Salt* do quite lose their sharpness and acrimony, so that the *Body* remaining after this their effervescence, is a meer insipid *Body*: But if then by distillation you separate the *Spirit* of *Vitriol* from the *Salt* of *Tartar*, you'll find that neither of them are deprived of their former *virtue* and *force*, but that they are as sharp and corrosive as before. All which *Experiments* do give us an undoubted evidence, that things after mixture retain the same nature they had before, and that *Mixture* is performed by Apposition of the Particles of one *Body* to those of another.

Mixture therefore or *Mixture* is nothing else but the Collection of divers *Bodies* into one, and that by way of Apposition. It may be performed divers ways. 1st. By Percolation or straining; thus *Blood*, *Urin*, *Medicinal Waters*, *Stones*, almost all *Juices*, *Wine*, *Oyl*, &c. are made.

2^{ly}. be.

VI. That Mixture is caused by Apposition.

VII. Experiments proving Mixture to be by Apposition.

VIII. What Mixture is, and how many ways the same may be.

2ly. By *Cottion* or by *Baking*, thus *Salt*, *Bricks*, *Earthen ware* and *Glass* become one mixt *Body*.
 3ly. By *Sublimation*, thus *Soot*, *Snot* or *Snivel*, and, it may be *Metals* also, and some *Salts* used by *Chymists* are made. 4ly. By *Distillation*; as many sorts of *Water*, *Rain*, *Dew*, *Manna*, and other things are made. 5ly. By *Dissolution*, thus *Salt-water*, the *Chyle*, or *nutritive Juice*, and dissolved or melted *Bodies* are made. 6ly. By *Exhalation*, as *Flame*, *Steams*, *Clouds* and other such like. 7ly. By *Concretion* or growing together, as *Snow*, *Frost*, *Hail*, the *Stone* in *Mans Body*, &c. 8ly. By *Calcination*, as many sorts of *Salts*, *Ashes*, *Quick-lime*. 9ly. By *Simple Commixtion*, as *Wine* mingled with *Water*, *Ointments*. 10ly. By *Simple Expression*, as *Wine*, *Oyl*, and most other *Juices*.

IX.
The Chan-
ges of Na-
tural
things.

Mutation or *Change* is the *Vicissitude* or *Alteration* of any thing, but chiefly of such as are bodily. The nature whereof we shall the better apprehend, by taking notice that all *Changes* are of two kinds, viz. *Accidental* or *Essential*. An *Accidental Change* is that whereby only some *Accidents* are changed, which do not constitute the essence of a thing, such as are the changes of *Heating* and *Cooling*. *Essential Changes* are those wherein the essences of things are changed by the *Introduction* of a *New Form*, and by depriving them of the *Form* they had before. And forasmuch as according to what hath been said in our *General Physics*, there are in the usual sense of the *Peripateticks* no substantial *Forms*, besides the *Soul* of *Man*, it follows that neither can there be in their meaning any *substantial change*, save that in the *production* of *man*, because in no other *production*, any such new *substance*, as they understand, is made; but in all *Alterations* and *Generations* the *matter* or *common subject* is only *Accidentally* or *Essentially* modified according to *Measure* or *Quantity*, *Rest*, *Motion*, *Position* and *Figure*.

X.
What Con-
version is.

To be more particular, *Conversion* is that *Action*, whereby one thing is changed into another, by the *Alteration* of its former *Modification*, and the *introduction* of another, diverse from the former, the same *common subject* still remaining. It is said that the same *Common Subject* remains: For the *Matter* which is the *Subject*, is numerically the same after the *Change*, as it was before, being only *Modified* anew. And this is well to be observed, because that otherwise it will not be any true *Conversion* or *Change* of one thing into another, but rather an *Exchange* of one thing for another.

XI.
The difference be-
tween an
Accidental,
Essential
and Sub-
stantial
Conversion.

That *Action*, which is terminated in those *Modes* or *Accidents* that may be present or absent without the destruction of the *Subject*, is called an *Accidental Conversion*. But that which is terminated in that peculiar *Modification*, which is *Essential* to any thing, and doth distinguish it from all others, the same is called an *Essential Conversion*, and sometimes *Substantial*, inasmuch as it affects the very *substance* or *subject* itself, so and so modified. For indeed by the *substance* of any thing we are not to understand that bare *Entity*, which is conceived to be the *Subject* of the *Form*, and to be specified by it, but both *Subject* and *Form* taken together, to wit, that *Thing* which consists of them both, or rather the *Subject*, as I said, itself, as considered with its peculiar *Modification*: So that

when this *Constitution* or *Modification* is changed, and another introduced into the common *Subject*, it is evident that then the former *substance* is also changed, and turned into another. Thus when that peculiar *modification*, which constitutes the nature of *Wood*, is changed, and the *Essential* disposition that constitutes a *Stone* is introduced, in this case we must say that the *Wood* is *essentially* and *substantially* changed into a *Stone*. And so likewise in the case of *Nutrition*, when *Corn* is reduced to *Flower*, that to *Bread*, and the *Bread* into the *Blood* and *Flesh* of our *Bodies*, this I say is an *Essential* and *Substantial Conversion*.

So likewise *Generation* is nothing else but a certain disposition of *matter* according to the fore said *Modifications* of *Measure*, &c. as in the *Production* of *PLANTS* and *BEASTS*; because in the generation of either of these, a new *substance* is no more produced, than in the framing of a *Statue*, or the building of a *House*. Now what happens to *Stone* or *Wood* when it is framed into a *Statue*, more than a new form or habitude in the matter of *Wood* or *Stone*? So likewise in the building of a *House*, there is no other change but what ariseth from the joining of *Stones*, *Boards*, *Tiles*, *Nails*, &c. which before were separate, but now being set together make such a compoſure or *structure* as hath the form of a *House*. And tho' the framing of a *Statue*, and the building of a *House* do terminate in a *Substance*, for both the *Statue* and *House* are *Substances*, yet no new *Substance* other than I have before asserted, is found in either of them, there being nothing superadded to them besides a new *Modification*, with which both these *Substances* are affected. Accordingly, *Generation* is nothing else but a translation or new ranging of the parts of *matter*, which is alike in *Natural* and *Artificial Compositions*.

As for *Corruption*, it is nothing else but the dissolution of parts that were before united. Thus as a *House* is said to be destroyed when its several parts are separated from each other; so *Wood* or other combustible *matter* is said to be corrupted or destroyed, when by *Flame* it is resolved into *Ashes* and *Smoak*. The Cause of the *Corruption* of *Bodies* is when strange particles, by thrusting themselves into their pores, do thereby change and destroy the *Texture*, *Connexion* and order of their *Parts*. Hence it is that those *Bodies* that have less pores, are for the most part more durable than others, and less subject to *Corruption* or *Destruction*.

Alteration is nothing else but the change, whereby a *subject*, still abiding the same, becomes changed as to some *Accidents*. So *Water* is said to be altered, when it is heated by the *Sun* or *Fire*: and a *Man* is said to be altered, when of *Healthful*, he becomes *Sick*, and of *Ignorant*, *Learned*, &c. Because *Man*, by supervening *Sickness* or *Learning* is not changed into another thing than he was before. And therefore *Aristotle* in the 1st. Book of *Generation* chap. 4. defines *Alteration* to be that whereby a sensible *subject*, abiding still the same, becomes changed in its affections.

Augmentation or *Growth*, to speak properly, is nothing else, but *Nutrition*, whereby more *substance* is restored, than was lost or dissipated. For *Augmentation* is never performed without local *Motion*, since nothing can grow or encrease, but by the

XII.

neration is.

XIII.

teration is.

XV.
What Aug-
mentation
or Growth
is.

the access or apposition of *aliment* to its parts, and by the union thereof with them. Thus when the *Innate Heat*, and *Temperament* of the *Body* are such, as that more prepared *Food* or *Aliment* is added to it, than it has lost, that *Body* is said to grow or encrease. As when a *Tree* by the *Juice* it draws out of the *Earth* grows taller, and spreads wider.

XVI. *What Diminution is.* The *Diminution* or *Decrease* of *Bodies*, is when this *Nutrition* ceaseth, and when less *Substance* is restored than has been dissipated or lost. The *Cause* of *Diminution* is, either the want of *Food*, or when the *Food* is not such as is proper to feed the *Body*; or because of the weakness of the *Innate*

Heat, as happens in those that are *Old*; or because the said *Heat* is too strong, as in those who are of a *Choleric* *Temperament*; or when the *Body* is so disposed, that it cannot be supplied with sufficient *Food*: Or lastly, when the little *constitutive parts* of the *Body* begin to waste and are consumed, whatsoever may be the cause of it; for then the *Musculous Parts* fall down, and grow *Flaggy* for want of a sufficient accession of new *Substance*, caused by a too sparing supply of *Food*, or because the same is not fitly prepared or concocted. Whence we understand that *Augmentation* or *Growth*, and *Diminution* do consist in *Local Motion*.

The Seventh Part

OF THE

INSTITUTION

OF

PHILOSOPHY.

OF

LIVING CREATURES

In General: And Specially of

PLANTS and ANIMALS.

The INTRODUCTION.

Of the Division of Living Creatures.

I. *The Division of Bodies into such as are living and destitute of Life.*

Hitherto we have considered the Nature of *Inanimate Bodies*, whether hid in the *Bowels* of the *Earth*, or exposed in the Face of the *Heavens*. And now we proceed to *Living Bodies*, viz. *Plants* and *Animals*, which are comprehended under this *General Notion*, because they are endued with *Life*, and are furnished with *Instruments* appropriated to *Nutrition*, *Growth* and *Propagation*. For all *Bodies* in the *Universe* are either *Living* or *devoid of Life*. Amongst those that are without *Life* are reckoned the *Heaven*, the *Stars*, *Fire*, *Air*, *Water*, *Earth*, *Metals*, *Stones* and *Fossils* or things dug out of the *Earth*: So that of all the *Creatures* contained in the *World*, *Plants* and *Animals* only are endued with *Life*.

II. *What Living Bodies are.* Now we call those *Living Bodies*, that have received from the *Author of Nature* such a *Disposition* of an *Organical Body*, as that by innumera-

ble passages and conveyances it hath, the *Alimentary Juice*, being by motion thrust into them, is by the *Soul* every way dispersed and distributed, for their *Nourishment*, *Growth* and *Conservation*. They are called *Living Bodies* from the *Life* they possess, and *Animate Bodies* from their *Soul*.

This *Soul*, a fit *Disposition* of *Parts* being first supposed, chiefly consists in the *Innate* or *Inborn Heat*, which is a *Heating*, but not a *Shining Fire*, generated in *Bodies* at their first *Production*, by means whereof the *Alimentary Juice*, for their *conservation*, is duly prepared, and distributed throughout the whole *Body*, and joined to the several parts of it, for a supply of that which daily wastes away, by which means *Vegetation*, that is, *Nourishment* or *Nutrition*, and *Encrease* or *Growth* are performed. And therefore this *Soul* is called *Vegetative*.

The *Life* flows from this *Soul*. For if the *Heat* be preserved and maintained by convenient *Mixture*, as its proper *Food*, then that *Body* is said to *Live*; and on the contrary to *Die* or *Perish*, when *Cold* and *Driness* do so predominate in it, as that the *Inborn Heat* becomes thereby diminished or quite taken away.

III. *What the Vegetative Soul is.*

IV. *Why a Body is said to live and die.*

N n n

Now

V.
There are
two Gene-
ral Heads
of Living
Bodies,
Plants and
Animals.

Now forasmuch as *PLANTS* and *ANIMALS* do both of them enjoy the common degree of *Life*, and resort under *Vegetable* as under their Immediate *Genus* or *General Head*, we must first consider their *Affections*, and whatsoever doth in general belong to them; as for Example, wherein chiefly the Nature of *Living Bodies* doth consist; how such as are *Vegetable* differ from those that are devoid of *Vegetation*; what that *Heat* is whereby they are *cherished and Live*, and whence their difference is deriv'd. For there are two *General Heads* of *Living Bodies*; the *First* whereof are those, which according to their outward and inward shape exhibit a *Substance* equally extended; and wherein from the top to the bottom we perceive but one and the same progress of *Nature*; so that all their parts are nourished, grow and are generated, without any distinction in their operations; their *Bodies* being as so many *Channels* and *Pipes* through which the *Food* is transmitted, and in which it undergoes several changes. And these are called *PLANTS*, which draw up an *Alimentary Juice* out of the *Earth* by their *Roots* into the *Stem* or *Stalk*, which from thence is convey'd and sublim'd to all the utmost parts.

VI.

The Defini-
on of a
Plant.

A *PLANT* therefore is a *Living Body* furnish'd with a *Skin*, *Strings*, *Root*, *Stalk* or *Stem*, and other *Organical Parts*, and is nourish'd, grows and produceth its like from prolifick *Seed*, only by means of a *Vegetative Soul*. So that all these *Plants* which spring out of the *Earth*, or grow in standing *Pools* or *Water*, or elsewhere, provided they grow and are nourish'd, whether they have *Roots* or not, whether they have *Leaves* or not, whether they have *Flowers* and *Fruit*, or have only a *Root*, all these, I say, are called *Plants*.

VII.

Plants are
divided
into Trees
and Herbs.

But forasmuch as the name of *Plant* doth not only belong to those *Bodies* which grow out of the ground by their *Roots*; but also to all those that grow upon other *Plants*, or that spring out of the ground some other way; therefore *Plants* by a general division may be distinguished into *TREES* and *HERBS*, as the two members that comprehend all *Plants*. A *Tree* is a *Plant* rising out of the ground with a *woody Stem* or *Stalk*, and growing up to considerable Height. An *Herb* is a *Plant* consisting of *Leaves* and a tender *Stalk*, never rising to the tallness or thickness of *Trees*. Some *Authors*, besides these 2 members, place a *SHRUB* as a third thing between a *Tree* and an *Herb*, but, as it seems, without any necessity, forasmuch as there be no *Plants* but may be conveniently reduced either to *Trees* or *Herbs*; a *Shrub* being nothing else, but a *Tree*, which rising out of the *Earth*, variously spreads it self into *Branches* and *Leaves* from the *Root*. For a *Shrub* riseth higher from the ground than an *Herb* doth. As to *Mushrooms*, &c. they may be reckon'd amongst those *Plants*, that grow upon other *Plants* or spring forth at their *Roots*. To which also may be referred some *Plants*, which do not spring out of the *Earth*, but from other *Plants*, such as are those small *Strings* that grow upon *Pulse*, and being intangled with them are carried upwards into the *Air*. As for *Moss* it may be well called an *Excrementitious Plant*, because from its original *Seed* it grows upon barren *Ground*, and *Stones* it self, in which it spreads its *Roots*.

VIII.

The Divisi-

Trees are commonly divided into *Wild* and *Domestick*, or such as are cultivated at home, and

those that are *Outlandish*: Not but that all *Trees* as on of Trees to their first original may be called *Wild*, as ha- into Wild ving grown first wild in the *Fields*: but because and Domes- there are many *Trees*, which men do not take the tick pains to *Transplant* and *Cultivate* in their *Gardens*, and if they should, yet would not they thereby change their wild *Nature*, whereas others being *Transplanted* and *Cultivated* by the industry of men, are much improved thereby.

The Second General Head of *Living Bodies* are IX. such as consist of a far greater variety and multiplicity of *Parts*, have peculiar motions, and seem to constitute many whole *Bodies*, which yet are joined together with that proportion, as to produce proper and necessary motions; so that from these different *Parts*, certain *Machines* or *Engines* do arise, most curiously wrought and contrived, which are called *Animals*, whose members are not only complete in themselves, but are also joined with that exact *Symmetry* and *Proportion*, as to conspire to the Good and Profit of the *Whole*, and concur to one motion. And notwithstanding that in the *Prædicamental Line*, and the *Genealogy* of *Things* and *Modes*, an *Animal* is, according to the common way of *Philosophizing*, constituted by something *Sensitive*, which is true too, in a certain meaning; yet we are to take heed that we do not by these means attribute to an *Animal* such a *Soul* and *Sense*, as has *Perception*; since the *Sense* of an *Animal* purely and alone consists in the impression of the *Object* on the *Bodily Organ*, which may be done without the Help of a *Soul*.

Animals are divided into such as *fly* in the *Air*, X. swim in the *Water*, go on the *Earth*, creep, slide The vari- along, or such as are altogether immovable. They ous kinds may likewise be distinguished from the difference of Animals. their *Generation*, *Parts*, *Actions* and other such like. And accordingly some are *Viviparous*, such as bring forth *Living Creatures*; others *Oviparous*, which lay *Eggs*, out of which *Animals* afterwards are hatched. As to *Parts*, some have *Wings*, others *Fins*, some go on two *Feet*, others on four or more. And others again want all these. As to their *Actions* or *Manners*, some are *Tame*, others *Wild*; some *Domestick* and *Sociable*, others delighting in *Solitude*; some *Stupid* and *Dull*, others *Quick* and *Cunning*. As to the places where they are bred and live, some are *Fiery*, others *Aquatick* or *Watry*, and others *Terrestrial*. Some live both on the *Earth* and in the *Water*, which are therefore called *Amphibious*; some are *Subterraneous*, or living under *Ground*, &c.

The most Noble and Excellent of all *Living XI. Creatures* is *MAN*, for the handling of whom we The Sum and Order design the Eighth Part of our *Institution*, as being of things to be treated the Complement of all *Animals*, and to express my self, as some of the *Ancients* have done, the of in this Horizon of *Heavenly* and *Sublunary* *Creatures*. Seventh Part. Now forasmuch as these *Living Things* do agree in some *affections*, we will here first touch upon those, which are common unto them all; and then in special apply our selves to the Contemplation of *Plants* and *Animals*, and shall at large set forth the distinction that is between them.

CHAP. I.

How Living Bodies differ from those that are Inanimate, and destitute of Life.

I.
The word
Life is
taken in
a threefold
significa-
tion.

IT appears from what hath been already said, that *Living Bodies* differ from *Lifeless things* in this, that the one have *Life*, and the other are devoid of it. But forasmuch as the word *LIFE* is *Aequivocal*, and attributed to things that are said to *Live* under different Notions; we must first consider what *Life* is, and how many significations it admits of. For the *Notion* of *Life* is very various and vagrant, but reducible to 3 General Heads. Sometimes we make use of this word to signify *Simple Existence*; sometimes, *Active Existence*; and sometimes also, *Coexistence*, or the *Duration of one thing with another*.

II.
What a
Life of
Simple Ex-
istence is.

That is a *Life of Simple Existence*, when the word to *Live* is taken simply for *Existence*: As when *BOETHIUS* defines *Eternity*, an *All at once* and *perfect Possession* of an *Interminable Life*. And in the same meaning *ARISTOTLE* calls the *Life of Animals*, their *Being*; because when they *die*, and cease to *live*, he thought they ceased to be also.

III.
What an
Active, or
Actuons
Life is.

An *Actuons Life*, is a *Life of Existence*, accompanied with *Action*; and in this Sense *Life* is taken for *Action* and *Operation*. Thus *Fire*, or a *Candle*, whilst it sends forth a *flame* is said to *live*; and so the *Vital Spirits* are said, to *live* in a *Body*, as long as they are in continual *motion*, and flow through the *Veins* and other hidden *Channels*. Thus we call *Spring-water*, *Living*, because it bubbles up, and flows continually; but *Dead*, when it stands still, and is without *motion*. In like manner, *Love* is said to be *alive*, whilst it is strong and active. So *Virgil*, in 1st *Aeneid*:

— with Lively Love
Strives to fore-stall.

IV.
What the
Life of
Existence
with ano-
ther is.

The *Life of Existence with another* is, when *Life* is taken for the *Duration* of one thing with another; or for the *Duration* of some *Substance*, in conjunction with some *Accident*, whereby it is perfected. Thus the *Life of Man* is commonly said, to consist in the *Conjunction* of *Soul* and *Body*, and his *Death* in their *Separation*: As when *CATULLUS* saith, *Let's Live my Lesbia*: Where, by the word *Live*, he understands *Existence* in conjunction with *Joy* and *Pleasure*. So that *Life* taken in this Sense, consists in the union of two *Substances*; or in the union of a *Substance* with some *Accident*, from which it borrows some kind of *Perfection*.

V.
Of the
difference
that is be-
tween Li-
ving and
Lifeless
things.

Living things are chiefly distinguish'd from *Lifeless things*, by the *Life of actuons Existence*, or because they are endowed with a certain *Efficacy* and *Activity*: For their *Life* properly consists in *motion*, which the *Purest* part of the *Blood*, if they be *Animals*, or of the *Alimentary Juice*, if they be *Plants*, communicates to the grosser parts of their *Bodies*: So that we find that *Plants* and *Animals* do soon perish, when the *Blood* by its *Circulation* ceaseth to quicken the *Members*, and when the *Juice* does no more enter through the *Pores*. For as *Bodily Life* consists in *Motion*, so *Death* consists in *Rest* or ceasing from *Action*. But for all this, we must not suppose, that there are any *Immaterial Souls* in *Living*

Bodies, that perform these *motions*, and the *Functions* of *Feeding* and *Growth*; it being sufficient that their *Parts* be so disposed, as that the prepared *Alimentary Juice* may freely enter into their *Inward parts*, and by its apposition, restore and supply their dissipated *Substance*. Now all this may be done by *Motion* alone, provided only that the *Parts* be rightly disposed, and that there be an equal *distribution* of the *Juice* by means of *Heat*. I say therefore, that *Living Bodies* differ from *Lifeless things*, in that the former, by reason of the want of *Organs*, cannot admit such a *distribution* of *Aliment*, for the *Restoration* and supply of what is lost.

If so be any one demands, by what *Force* or *Activity* this *Juice* is diffused through the *pores* and *passages* of the *Body*, to all its *parts*, so as that they grow not only in *length*, but also in *breadth* and *depth*?

I Answer, That this is done by means of *Heat*, proceeding either from the *Sun*, or from *Fire*. For such is the *Efficacy* of the *Heavenly matter*, that is, of the *first* and *second Element*, that by passing through the thicker *Particles* of the *third Element*, it doth agitate them, and in so doing doth produce or excite *heat* in them; by which means these *particles* being rarefied, are carried upwards through the *Pores* of the *Roots*, to the *Stalk* or *Trunk*, and all other *parts*. Besides, there is in all *Living Bodies* a certain *Inborn* or *Native heat*, or rather a *fire* that is *hot* only, without *Light*; by the assistance whereof the *Alimentary Juice* is distributed through the whole *Body*, and joyning it self to it, doth preserve, enlarge and perfect it.

Living Bodies also differ from such as are *Lifeless* or *Inanimate*; because these latter are not determin'd to any certain *figure*. Thus *Stones* may subsist under any *figure*: Some are 6 Corner'd, as *CRYSTAL*; some have a *crooked Surface*, as *FLINTS*; some have a *plain surface*, like a *Plate*, as *TALCK*; some have the *figure* of a *Lozenge* or *Quarry* of *Glass*. So likewise *Metals*, and all other *things* dug out of the *Ground*, do not require any *One precise figure*. But *Plants* and *Animals* cannot admit this variety of *figures*, as requiring a certain and determinate *Conformation*. For a *Plant* cannot be of any *figure*, but must have such a one, as is necessary for the *drawing*, *concocting*, *digesting*, and *distributing* of its *Aliment*. And 'tis for this Reason, that *Living things* only are furnish'd with *Organical Bodies*, which consist of such *Instruments*, as are proper to perform the several *Functions* of *Life*; such as are the *Root*, the *Stem* or *Stalk*, the *Branches*, the *young Shoots* in *Plants*; and the *Feet*, *Belly*, *Head*, *Bones*, &c. in *Animals*. Wherefore also a greater *Beauty* is found in the *Bodies* of *Living things*, than in *Artificial*; for since *Beauty* consists in *Variety*, it is evident that in *Living Bodies* there is a much greater diversity of *Parts*, than in others, whose *parts* are not so numerous, nor so fine and curious, nor so exactly and neatly joyn'd together.

Altho' in an *Artificial Engin*, or *Machin*, as likewise in a *dead Carcass*, or a *wither'd Plant*, there be many such like *Organs*, as are found in *Living Bodies*; according to what *Historians* relate of that *Wooden Eagle*, made by *REGIO-*

VI.
By what
force or
virtue the
Alimenta-
ry Juice is
distributed
through
the Pores
of Living
things.

VII.
Lifeless
Bodies are
not subject
to any cer-
tain figure,
as Living
Bodies are.

VIII.
Artificial
Bodies are
not capable
of Growth
and New-
ment.

MON-

MON T A N U S, which did fly in the *Air*, and shewed the way to the *Emperour*, as he was going to *Nuremberg*; and of the *Wooden Venus*, made by D A E D A L U S, which could walk by the Artificial putting of *Quicksilver* into the Inward parts of it: Yet for all this, *Living Bodies* are very distinguishable from such *Artificial* or *Dead Bodies*; because they are nourished and grow, by the *Alimentary Juice* admitted into their *Pores*; whereas *Artificial* and *Dead things* are neither capable of *Growth* nor *Nourishment*.

IX.
Living
Bodies are
productive
of their
like.

Lastly, Herein also are *Plants* and *Animals* differenced from *Metals*, and other *Dead Bodies*; in that they can produce their like, and preserve their kind by a successive propagation of *Individuals*; which things dug out of the *Earth* are not capable of, as being destitute of *Seed*, or any *Virtue* whereby to generate an Off-spring.

CHAP. II.

The Life of Bodily things consists in Moisture and Heat.

I.
Living
Bodies
stand in
need of
Heat and
Moisture.

FORasmuch as such is the Constitution of *Living Bodies*, that they consist of several fibres or small threads, between which lye many large Conduits or Passages, through which the *Alimentary Juice* is strained, and diffused into all parts; it cannot be question'd, but the *Life* of *Plants* and *Animals* is supported by 2 things, viz. *Heat* and *Moisture*, which mutually stand in need of, and assist each other. For *Moisture* is the food of the *Heat*: And accordingly *Physicians* tell us, that *Life* consists in *Moisture*, as its *Passive*, and in *Heat*, as its *Active Quality*; and that all *Vegetative Bodies* do subsist and are preserved by the same.

II.
The Fire
that is in
Living
Bodies, is
Hot only.

But to remove all Difficulty that might arise from the word *Heat*; we are to take notice, that we do not speak here of a perfect *Fire*, which is both *hot* and *bright*, but of that which is *hot* only; such as is found in *Horse-dung*, and putrifying *Hay*: Which is therefore distinguish'd from the *Celestial fire* in the *Sun*, and from the *Elementary*, which burns upon our *Hearths*; because it doth not consist as those fires do, of *Particles* that swim in the first *Element*, and are tost with a vehement *Motion* within themselves; but proceeds from a kind of *fermentation*, caused by a mixture of *Heterogeneous little Bodies*. Tho' indeed, if we well mind its Operations, we shall find it to differ from the 2 former fires, *Solar* and *Culinary*, rather in degrees, than in nature and essence.

III.
There is a
twofold
Tempera-
ment in
Living
Bodies.
The one
according
to Justice.

But forasmuch as *Fire* is very *Active*, and cannot long be preserved without food, we find that *Moisture* is of absolute necessity required for its preservation and support. From hence ariseth the Temperament of *Living Bodies*, when *Heat* and *Cold*, *Moisture* and *Drought*, are so temper'd and proportioned, that none of these *Qualities* hinder each other, but with an agreeing *Discord* harmonize together. And this kind of Temperament is by *Physicians* called, a Temperament according to *Justice*, when these *Qualities* are so mixed, that the *Heat* in *Living Bodies* is qualified by *Cold*, and the *Moisture* by *Drought*, according to the requirings of each particular *Nature*. Because the same Temperament is not always found in

Living things, but is changed according to the variety of *Ages*, or the several Stages of *Life*. For in *Animals*, to every different *Age*, a different Temperament is appropriated; to *Childhood*, a hot and moist Temperament; to *Youth*, hot and dry; to *Manly Age*, cold and moist; to *Old Age*, cold and dry Complexion. And these Temperaments are therefore said to be according to *Justice*, because they of Property and Justice belong to such and such *Ages*.

To this Temperament another is opposed, which is called a Temperament according to *Weight*, wherein all the *Qualities* are in an Equal poise; so as *Heat* doth not exceed *Cold*, nor *Cold*, *Heat*: *Moisture* doth not exceed *Drought*, nor *Drought*, *Moisture*; but are altogether equal in degrees. But it does not seem probable, that any *Body* is posselt of such a Temperament, neither is there any Cause assignable that might thus temper and poise these *Qualities*; and therefore this is a Temperament in Notion only, as G A L E N saith, and not Real.

Forasmuch therefore as *Heat* and *Moisture* are required to a due *Vegetation* of *Living Bodies*, it happens, that according to the Exuperance of either of these *Qualities*, a more abundant production of *Living things* is occasioned. Thus in *Summer time*, when *Heat* bears sway, abundance of *Magots* breed in *Flesh*, *Bees* in the *Carkass* of an *Heifer*, *Humming-Bees* or *Drones* in that of an *Ass*, *Hornets* in that of a *Mule*, and *Wasps* in the *Carkass* of an *Horse*: It is in the same Season also, that *Dead Flies* recover *Life*. And accordingly it will not be difficult to give a Reason, why *Spices* grow only in *Hot Countries*, because they stand in need of a great degree of *Heat* before they can arrive to that Purity, by a separation of the *Heterogeneous particles*, that so the *Homogeneous* may come together, and constitute those *Odoriferous Bodies*. And therefore, as my Lord V E R U L A M tells us, *Trees* planted on a *hot-Bank*, and exposed to the *South* and *South-East*, do bud sooner than others, and bring forth more early fruit. And the same he saith of *Trees* planted near the *Wall* of a *Chimney*, wherein continual fires are kept; and that it is good for the same purpose, to let the *Branches* of *Trees* spread into those places where frequent fires are used. Of which we have a pregnant Instance in *Vines*, which according as they are more advantageously situated, do by a whole *Months* time, sooner than others, bear *Ripe Grapes*.

It is for this very Reason, that *Country-men* do *Dung* their *Grounds*; not only because the *Dung* doth fatten the *Earth*, whereby more plentiful Nourishment is convey'd to *Plants*; but also because by its warmth it comforts and refresheth the *Ground*, which was weak and languishing by reason of *cold*. For the *Dung* of *Animals* is *Salt*, and contains an *Inward heat*. And accordingly we find, that those who desire to hasten the springing and growing of their *Plants*, do take care very well to *Dung* their *Gardens* and *Plots* of *Ground*, before they sow their *Seed*. To this end also they pour stale *Urine* at the *Roots* of *Vines*, to make them more fruitful.

As store of *Heat* doth conduce to the great increase of *Plants* and *Fruits*, so much *Moisture* also is a great help to the multiplication of them,

increase of
Living
things.

when accompanied with convenient heat and warmth. Thus we find, that in Moist places Grass grows thicker, and riseth to a greater height, than in Dry Grounds. In like manner we see, that Herbs will grow in Glass Vials, fill'd only with Water. We find also, that the Hair of Young-men and Children grows much faster and thicker, because Moisture abounds in them: And Trees and Plants, that are much water'd, do thereby thrive the more; for by frequent watering, the Dryness of the Soil is temper'd, and the Roots are softned, and thereby made more fit to suck the Juice out of the Ground, and to send it up to the utmost Branches. So the fittest time for the watering of Plants, is the Evening; because the Cool of the Night following, gives the Moisture leave to sink down to the Roots, and refresh them.

VIII. How greatly Moisture conduceth to Germination, may be gather'd from Moss, which delights in moist places, and grows even upon those Rocks and Stones that are continually water'd with Springs. Hence it is also, that Bread that is kept in a moist Cellar grows Mouldy, and many other things that are laid up in moist places.

IX. As an equal Temperature of Heat and Moisture, is the Cause of the great increase and multiplication of Living things; so the Excess of either, and more especially of Heat, is hurtful to them, and hinders them from arriving to their due growth. Thus we see that Bodies, wherein the inborn heat predominates, are of a low stature, because it consumes the Moisture too fast, not suffering it to spread and diffuse it self; and so also such Persons, in whom Heat abounds, are commonly lean: Whereas on the contrary, those in whom this innate Heat is weaker, and allay'd with Moisture, are apt to grow fat, and spread in bulk; as is evident in Women, who commonly are more Plump and Fat than Men, except Sickness, or any Præternatural Cause hinder the Effect.

C H A P. III.

The Death of Living things proceeds from contrary Principles, viz. from Cold and Driness.

I. Wherein the Death of Living things doth consist. Forasmuch as contrary Effects proceed from contrary Causes, we may easily conclude, That the Death of Living Creatures are owing to Cold and Driness. For as the Bodily Life consists in the due Temperature of Heat and Moisture; so Death happens to them through the predominance of Cold and Drought, whereby the Vital Principle of inborn Heat, becomes weakned and destroyed. Bodily Life, as hath been said, consists in continual Motion; wherefore when any Cause happens to fore-slow, or put a stop to this Motion, Life must cease also. Now, since nothing is more opposite to Motion, than Rest, wherein the Nature of Cold doth consist, it cannot be question'd, but that where Cold prevails, Death must enter. Thus we see Flies dye at the approach of Winter; and that Frogs, tho' they live in the Water, and are in a great measure habituated to Cold, yet perish in Frosty-weather. For as great Cold doth congeal the Waters, and hinder their Motion; so the over-slow agitation of the Spirits and Humors in the

Body of Man, is hurtful to the Life of the Body; and where it is of long Continuance, quite destroys the same. And in like manner also, excessive Cold causeth the dying of Plants and Trees.

For tho' Heat and Cold be contrary Qualities, yet do they by opposite ways produce the same Effect, viz. Drought. For we find that Clay is dried by hard Frost, as well as by great Heat in Summer: The Reason whereof is, because all liquid and moist Bodies, lose the agitation of their Particles, by Cold, and by this means become hard and dry: And therefore it is no wonder, if Clay, which is nothing else but a Mixture of Water and Earth, should grow hard and dry, because the Water which softned it, is by the cold congealed. Seeing therefore that cold works the same effect in Plants, it cannot seem strange to us if Plants perish, when the Juice wherewith they were nourished, is frozen. It has been of Old told us, that extream Cold scorcheth and burns up Plants, by congealing and drying up their Moisture and Alimentary Juice.

Hence also it is, that in Cold Countries the Leaves begin to fall from the Trees towards the latter end of Autumn; because about that time, the pores of Plants are shut up at the approach of Cold, and the Passages along which the Juice is conveyed, are dried up and contracted.

And as Cold produceth these Effects in Living Bodies, so doth excessive Heat also; for Heat exhausts the Spirits and Humours, and attenuates and wastes the Bodies in which it doth predominate. For as a Mill, without the assistance of Wind or Water, stands still without any motion at all; so Plants, upon the consumption of their Alimentary Juice, perish; and Animals, when their Spirits and Humours are weakned by extream Heat, languish and are slowly moved. Whence it comes to pass, that when great Heats happen in Hot Countries, at the time when the Ears of Corn begin to break forth, they are stopped in their coming forth; because the Moisture being by the heat dissipated into the Air, the Heat finds nothing to feed upon, or whereby to maintain it self.

The Death therefore of Living Bodies happens, when Moisture, which is the food and fuel of Heat, is wasted; or when Heat is separated from, and leaves the Moisture, which then ceaseth to be agitated, and distributed to all parts of the Living Body. For as Flesh laid before a slow fire, is roasted, and by exhaling of the greatest part of its moisture becomes quite dried up; so the Temperament of Living Bodies becomes spoiled, when the Spirits and Humours are alter'd and wasted by excess of Heat. Thus Fruits are frequently spoil'd by over-much heat, which scorching their outside, leaves their inward substance raw and unripe; as it happens to Grapes and other Fruits, whose outside is often scorched with that heat, which scarcely toucheth their Inward parts: As Bread put into an Oven that is over-heated, hath its Crust burnt up and scorched, whilst the midst of it wants baking, and is doughy.

But you'll say, If Driness be the Cause of Death, how can Fishes that live in the Water, ever arrive to that degree of Drought, which may cause their perishing or death? I answer, That the Water in which the Fishes swim, cannot hinder the wasting and drying up of their Natural moisture: As

II. Cold drieth as well as Heat.

III. Why the Leaves of most Plants fall in Autumn.

IV. Heat is hurtful to the Aliment of Living Creatures.

V. When the Death of Living Creatures happens.

VI. How Fishes are dried up in the Water.

we find that *Flesh*, which is suffer'd to *boil* in a Pot full of *Water*, till all the Natural moisture be consumed, becomes harder than that which is *roasted*. Yea, we find also that some sorts of *Wood*, that have lain long in the *Water*, are found drier and lighter when they are taken out, than when they were put in.

VII. Neither is excessive *Heat* only an Enemy to *Living Bodies*, but even to all in general: Thus we find that when the flame of a *Candle* or *Torch* is increased, it doth so much the sooner consume and waste the *Body* that serves it for *fuel*; and by a parity of Reason, when the *Heat* either outward or inward exceeds, it procures the *Death* of *Living Bodies*: As we find that *Plants* wither by excessive *heat*; and that *Men*, by indulging themselves in the drinking of *hot Liquors*, do hasten their own *Death*.

VIII. Sometimes *Death* happens to *Living Bodies* by defect of *Food* convenient; as when *Nature* ceaseth to furnish them with *Matter*, whereby they might grow and be nourished: For so in *Plants*, tho' it may be there wants no *Moisture* for the *Heat* to act upon, and tho' the *Sun* have force enough in *Summer time*, to draw up the *Juice* out of the *Earth*; yet is not that *Fervescence*, or *Fermentation* of the *Alimentary Juice*, which is requisite to their *Vegetation*, always performed alike; for it requires a certain and determinate Season of the *Year*, which being once past, it cannot afterwards be expected. An Example whereof we see in *Quick-Lime*, which upon the affusion of *Water* causeth an *Effervescence*; but that being once ceased, it cannot be renewed again, tho' you should pour never so much *water* upon it. And for this cause it is that ripe *Fruits*; as *Apples*, *Pears*, *Plums*, &c. do fall down to the *Ground*, as soon as their *Stalk*, whereby they were joyned to the *Tree*, begin to want *aliment*, and those *fibres* that held them fast are dried up. And the same is the Reason, why all other *Fruits* and *Grains* fall out of their *Husks* and *Pods*.

IX. And much like Effects do sometimes proceed from the too great relaxation and opening of the *Pores* of *Bodies*: For thereupon the *Bodies* contained in those Intervals must needs fall down, except that by some means or other their *bulk* be coextended to the amplitude of the *pores* wherein they are. Thus, when in the *Summer Season* the *pores* of the *Skin* are more open, the *Hides* of *slay'd Beasts*, have the *Hairs* more easily pluck'd off. Thus likewise it seems probable, that the falling out of the *Teeth* of *Children*, is caused by the dilatation of the *Sockets* of the *Jaw-bone*, wherein the *Teeth* are fixed; for they growing wider, as the *Child* advanceth in bigness, they can no longer keep the *Teeth* steady. But in *Old People* this falling out of *Teeth* is caused by the defect of *Aliment* and *Moisture*; because the *fibres*, through which the *Aliment* was used to be convey'd to them, grow dry and are contracted.

CHAP. IV.

What is the Cause of that *Hardness*, which is observ'd on the outside of *living Bodies*.

I. The *Hardness* of *Bodies* consists chiefly in this, that they resist the *Touch*, and that their parts are not easily separable from each other.

And forasmuch as this Resistance to the *Touch* is perceiv'd on the outside of *Living Bodies*; it will be worth our enquiry, What might be the Cause of it, that when their Inward substance is so soft, their outside should be hard. Whereof no other Cause seems assignable, but this. That the Outward parts of *Living Bodies*, are expos'd to the continual impulse of other *Bodies*. For it is certain, that the *Heavenly matter* (under which Name we do not only comprehend the Matter of the first and second Element, but also the *Air*, with the Particles of the third Element that are mix'd with it) carries the *Earth* round; and forasmuch as all these Small *Bodies* cannot pass through the *Earth*, or any of the *Bodies* which belong to it, it cannot be otherwise, but that vast numbers of them must dash against *Living Bodies*, and by their continual beating upon them, render them hard. For by this impulse, their Outward parts are driven closer together, and so become more Compact and Hard.

For to speak properly, the *Hardness* of *Bodies* is nothing else, but the *Rest* of many *Essential* or *Integral parts*, caused by the Pressure of the *Air*, or of the *Subtil matter*; which acting only on the outside, doth so much drive those *Particles* inwards, that they can no more be separated, without a perception of some Resistance. For tho' the *Subtil matter* doth penetrate all *Bodies*; yet we are to consider, that the Parts of many *Bodies* are so great and irregular, that they are able to resist its Action and continue at *Rest*, and by this means constitute *Hard Bodies*; because they resist or oppose their being divided, and are outwardly so compress'd by the *Air* and the *Subtil matter*, that it is oftentimes more easie to move them altogether, than to separate them from one another.

This is the Cause of those Coverings, which do invest some *Living Bodies*; as we find that *Acorns* have *Cups*; *Nuts* have *Shells*; *Beans* and *Pease*, *Pods*; and *Trees*, *Barks*: So likewise *Fish* have *Scales*, and some of them hard and stony *Shells*; as *Oysters*, *Crabs*, *Lobsters*, &c. All which without doubt are formed, by the continual impulse of outward *Bodies*; much in like manner as we find, that the *Palms* of the *Hands* of *Delvers* and *Ditchers*, by continual handling of the *Spade*, grow very hard; and as the *Soles* of our *Feet* become brawny and thick *Skin'd*, by assiduous beating against the *Ground*.

They are the same Causes also that produce *Hardness* in *Inanimate Bodies*. For *Snow* laid near the *Fire* becomes harder and more compact; and the outside of *Bread* becomes hardned to a *Crust*; and so likewise the outside of *Flesh roasted*, *broiled*, or *fried*, grows harder than the inside. Neither can any other Reason be given, why *Bread*, *Boil'd Milk*, and other kinds of *Supping Meats*, presently after they are removed from the *Fire*, get a *skin* or *film* on the top of them, but this, that the agitation of the *Heat* is diminished by the contact of the *cold Air*, and in a manner quite stopt.

Hence it is also, that the *Surface* of all *Liquors* is smooth and even; for tho' the Parts of *Water* be uniformly moved, as well as the *Air*, which immediately toucheth them; yet because the parts of the *Water* are moved after another manner, than those of the *Air*; and that the *Subtil*

Surface of *Living Bodies* doth proceed.

II. Wherein the *Hardness* of any *Bodies* doth consist.

III. Whence the *Covers* of some *Living Bodies* do proceed.

IV. The same is the Cause of the *Hardness* in *Inanimate Bodies*.

V. The *Surface* of all *Liquors* is smooth, and more difficultly divided than its inward parts.

matter which surrounds the parts of the Air is quite otherwise moved than that which swims amongst the particles of the water; by this means the surface of either of them becomes smooth, much after the same manner as when two Hard Bodies are rub'd against one another; only with this difference, that this smoothness is with much more ease produced in liquid Bodies, because of the ease and ready Mobility of their Parts. And this is the reason also why the surface of the water is divided with more difficulty, than its inward parts.

VI. Cold also conduceth much to the Hardning of several Bodies: for we see that the surface of water in a River, by cold is congealed, whilst that which is at the bottom, by reason of the stronger motion of heat, suffers not the least alteration; and so also are many other Bodies sometimes hardned by cold, and thereby attain that degree of firmness, which is caused in them, by other Bodies beating upon them: For frozen Fruit, if it be put into cold water, and set in a warmish place, will appear covered over with a Crust of Ice, and in like manner the Flesh of Beasts or Fish that is frozen, if it be set in a warm place covered with Snow, there will appear a hard Crust of Ice on the surface of it.

VII. But tho' cold may sometimes contribute to the hardning of Bodies, yet this effect may with greater Right be attributed to Heat, whose property it is to agitate the parts of Bodies, and bring them closer together, by exhaling their superfluous moisture. Thus a Body exposed to the Beams of the Sun, as by this means it becomes better digested and riper; so likewise it attains a greater degree of firmness and hardness. This is manifest in Apples, Pears, Cherries, Plums and such like, whose outside by the Heat of the Sun becomes hardned, and covered with a Skin.

VIII. But which way soever this Hardness may be produced in Bodies, it seems that they are all reducible to one general Cause, forasmuch as their outward parts endure the impulse of other Bodies rushing against them and dashing upon them, and by hindring their ingress, do resist and beat them off.

CHAP. V.

Of the Different Degrees of Heat in Living Bodies.

I. THO' Living Bodies may be distinguished according to the External Heat that Acts upon them, as they are in Countries or Places nearer or farther from the Sun: yet may they much better be differenced by that Internal Heat, which produceth divers Effects in them with relation to their Age, Sex and Nature. For as to their Age, it is evident that Heat in Living Bodies is not always in the same state and vigor. For in Infants and Youth the natural Heat is much weakned by the abundance of moisture, that it cannot exert its full strength; which is the reason why Infants are so prone to sleep, and apt to shed tears. But in the Height and Vigour of Age, the Heat is more strong and active; and the moisture being much lessened, the Spirits become more hot and fiery. For which cause those who have attained to Manly Strength, are more strongly inflam'd and Amorous,

whereas in Old Men, by the decrease of heat, and the increase of cold and driness, their natural faculties are much weakned and decayed.

Difference of Sex also produceth great diversity of Heat; for Females are commonly of a more cold and moist complexion than Males. Which difference is observed in Plants; for those are accounted Female Plants, which are more cold and moist, and have less virtue and strength; so that tho' they bring forth Flowers, yet for want of Heat they don't produce either Fruit or Seed. Whereas the Male Plants are more beautiful, as to their outward appearance, and have both Fruit and Seed. And for this cause it is, that the Female Plant delights in the Company and Proximity of the Male; according to what PLINY relates of the Palm-tree, which by some influence proceeding from the Male, doth conceive and become fruitful, and as soon as the Male, which stood near it, is cut down, dies presently.

Amongst Animals also the Females are much colder and moister than the Males. As may be gathered from hence, that Males generally exceed Females in Bulk and Stature, as appears in Men, Pheasants, Peacocks and the like. The Males in Birds are commonly more beautiful and pompous for their Feathers. Amongst fourfooted Beasts the Males and Females are diversly distinguished; thus He-Goats have Horns, which their Females want; and Rams have greater and more crooked Horns than the Ewes. Cocks are adorned with Combs, and armed with Spurs; whereas Hens have in a manner no Combs at all. And in general all Males have a stronger and deeper Voice than Females, who generally have but a shrill and weak voice. All which effects cannot be better assign'd to any other cause, than to the greater degree of heat which is in Males, beyond that which is in Females. And the same may likewise be gathered from hence, that Males, in their tender years, whilst their inborn heat is overpowered with too much moisture, do much resemble Females, neither is any difference in their Temper to be discern'd between them. So likewise gelded Animals do more resemble Females, for the same defect of heat.

Another instance of this diversity of Heat in Males and Females is this; that Men, during the Winter Season, are more Brisk, and Women on the contrary, in the Summer and hot weather. The reason whereof is, because the Vital Spirits, which are in continual motion in a hot and dry complexion of Body, such as Mens are in the hot season of the Year are more dissipated; but in a cold season are more condensed, and thereby better preserved. Whereas in cold and moist Bodies, such as those of the Female Sex generally are; the Heat of the Summer cherisheth and excites the Spirits; and the cold of the Winter doth render them dull and sluggish.

There is also a distinction and difference of Heat with relation to the different kinds of Living Things. And accordingly Physicians distinguish Heat into 4 degrees: They call that the First Degree of Heat, when that Quality is somewhat predominant above the rest that are in the mixt Body: The Second when the Heat sensibly discovers its predominance in the Body: The Third, when it strongly and powerfully displays itself:

II. Secondly according to the difference of Sexes, and what the difference of Sex in Plants is.

III. Amongst Animals the Females are colder than the Males.

IV. Why Men in the Winter time are more brisk, and Women in Summer.

V. Of the four degrees of Heat that are in Living Bodies.

self: And the *Fourth* when that *Quality* is prevalent in the highest degree. Thus amongst *Plants*, *Borage*, *Flowers of Betony*, *Beets*, *Sweet Almonds*, &c. because they impart some small effect of *Heat* to a well tempered *Body*, are said to be *Hot* in the *First Degree*. *Smallage*, *Betony*, *Balm*, *Rosemary*, *Wormwood*, *Saffron*, *Sage*, *Cinnamon*, &c. because they produce a moderate *Heat*, and that very sensibly, are called *Hot* in the *Second Degree*. And because others impart a strong *Heat* to those that take them, as *Origany*, *Hyssop*, *Celandine*, *Mints*, *Radish*, *Mother of Tyme*, &c. they are accounted *Hot* in the *Third Degree*: And last of all, because *Garlick*, *Pepper*, *Mustard*, *Cresses*, *Pellitory of Spain*, &c. communicate a much more vehement degree of *Heat*, they are called *Hot* in the *Fourth Degree*.

VI. This Distinction of *Heat* is not only observable in *Plants*, but also in *Animals*. For we see daily that those *Excrements* which remain after that the *Meat* hath been digested by the heat of our *Stomachs*, serve for food to *Hogs* and *Hens* after having past through a new *Fermentation* in them; and that the remainders thereof being laid to the *Roots* of *Plants*, are consumed again by the *Heat* of the *Sun*, leaving only the grosser parts behind them. Which different changes could not be wrought upon those *Excrements*, if there were not different degrees of *Heat* in the *Bodies* of *Living Creatures*, forasmuch as that which can no further be wrought upon by the *Fermentation* of our *Stomachs*, may yet be further altered and digested by a new *Fermentation* in the *Stomachs* of other *Animals*. Thus a *Mass* of *Dough* that hath been fermented by *Leaven* or *Yeast*, tho' it cannot be made to rise again with the same ferment; yet may it for all that undergo a new *Fermentation* in our *Stomachs*: Which *Alterations*, I say, do prove a distinction of *Heat*, and a different power of dissolving *Bodies* to be in *Living Creatures*.

CHAP. VI.

The Virtue and Nature of Aliments remain in the Bodies that are Fed and Nourished by them.

I. **T**HO' *Aliment* or *Food* in *Living Bodies* be digested by the *Natural Heat*, and by that means becomes changed into their nature, yet it is not so entirely assimilated to them, as not to retain some of its former *Nature* and *Virtue*. This appears from our *Excrements*, which tho' by the heat of our *Stomachs* they have been separated from the thinner parts of our *meat*, and as it were changed into a quite different substance, yet retain something of the *virtues* and *qualities* of those *Bodies* whence they have been separated, and often preserve something of their *colour* and *smell*. Thus they who eat any quantity of *Black Cherries* or *Myrtle Berries*, will find their *Excrements* ting'd of a *Black Colour*. And *Sparagus* and *Turpentine* after having passed through the *Stomach* and other *Organs* of *Nutrition* communicate their *Odour* to the *Urine*.

II. If therefore so great *virtue* of the *Food* do still remain in the *Excrements*, with much more reason may we conclude, that the same much more abides in the *Bodies* that are nourish'd by, and receive

their increase from them; forasmuch as the more pure and *Juicy* part of the *Food* abides with them, which doth most abound in *virtue*. And tho' *Animals* void many *particles* of their *Aliment* by *Siege*, by *Urine*, by *Sweat* and by *insensible Transpiration*; yet cannot this hinder us from concluding that many *Particles* of *Aliment* must remain in the *Bodies* of those *Animals* that are nourish'd and grow by it. Hence it is that *Country People* that feed upon *Beef*, *Bacon*, *Cheese*, and such like strong *Food*, which nourish much, but are somewhat hard of *Digestion*, are much more strong in *Body* than those who feed upon *Dainties*, who generally are weak and unfit to endure labour. Who doth not find in himself a different state of *Body* when he drinks *Wine*, than when his ordinary drink is *Beer*, *Ale* or *Water*? And do not those that fare deliciously and feed high, find themselves more ungoverned in their *Passions* and *Lusts*, than those who live abstemiously, and content themselves with necessary *Food*?

The *virtue* of *Aliment* is more particularly discernible in the *fruits* and *products* of *Plants* and *Animals*, which differ, according to the diversity of the *matter* whereof they are formed. Thus *Milk* is not always qualified alike, but according as the *matter* of it is drawn from such or such *Plants*, its *virtues* and *qualities* vary. *Cows* that feed upon *Grass* yield a very different *Milk* and *Butter* from those that eat *Straw*. It is a matter also of common *Experience*, that *Cows* that in their feeding light upon *wild Garlick*, communicate a strong taste of *Garlick* to their *Milk*; and that the flesh of *Sheep*, which feed upon *wild Thyme* hath a much more grateful taste than that of others. *GALEN* makes mention of a certain *Medicinal Milk* which is very prevalent in the cure of the *Schirrus* or hard swelling of the *Liver*; the *Cow* that yields it being made to feed on some peculiar *Herbs* conducing to that end. The story also of that *Young Woman* is well known, who having used herself to the eating of *Wolfs-bane* (which is a most poisonous *Herb*) tho' she found no hurt by it herself, yet was the death of those *men* that lay with her.

Physicians likewise do observe, that if the *Milk* of a *Goat*, that hath fed upon some purging *Plant*, be eaten by a *Nurse* that suckles a *Child*, it will communicate its purging *virtue* to the *Nurses Milk*, and purge the *Child* that sucks it. It is known also that the *Milk* of *Cows*, and the *Butter* made of it is far better in the *Spring*, when *Cows* feed upon tender *Herbs* and *Flowers*, than at other times. So likewise it is observed that the *Honey* which the *Bees* gather from *Thyme*, *Sage*, *Savory* and *Tree Trefoile*, being the *Herbs* they most of all delight in is the best of all other. For this reason the *Honey* of *Sardinia* hath a bitter taste, because it is mostly gathered from *Wormwood*. And *Historians* tell us, that the *Honey* made about the *City Heraclea* in *Pontus*, had a venomous quality, because it was gathered from the poisonous *Aconite*.

The same may be also experienc'd in *Wine*, which being adulterated with *Quick Lime*, *Plaster of Paris*, *Rocket*, *Wild Myrtle* or *Butchers Broom*, *Ferus Lime*, *Clary* and the like, becomes pernicious to the *Body* of *Man*. There are also some sorts of *Wine* which do particularly affect our *Dispositions*.

mains with the Body that is fed.

III. Milk is differently qualified according to the difference of the Pasture the Cows graze in.

IV. Herbs after they are turned to Blood retain their purging virtue.

V. The Ground or Soil in which the Vines grow, communicates to the Wine some of its virtues.

ations. It is an Observation of *LEMMIUS*, alter'd, being sometimes meliorated, and sometimes again degenerating, as the *Climat* doth agree, or disagree with them. And this, because of the difference of *Heat* and *Cold*, *Moisture* and *Dryness*, that predominates in those Countries; for according as the *Climat* or *Soil* of any Country differs, so the disposition of those Bodies that are there differ also. Thus some *Plants* grow much taller and fairer in some Countries and Soils, than in others. Some *Plants*, being removed to a better *Air* and *Soil*, are thereby meliorated and bring forth wholesome *Fruits*; whereas in their *Native Soil*, they brought forth deadly and poisonous *Fruits*. As *COLUMELLA* acquaints us with a certain *Plant*, which by being removed from *Persia* to *Egypt*, loseth its venomous *Quality*, and becomes wholesome to those that eat it.

The *Virtue* of *Food* is also perceiv'd and distinguish'd in *Animals*. For in some parts of *Holland*, which is a *Watry Country*, and abounding with *fish*, they fatten their *Hogs* with them; which tho' they soon fat them, yet it is observed that the *Flesh* of these *Swine* is more flaggy and less firm, neither is it so wholesome; and differs much in Taste from the *flesh* of those *Swine*, which have been fed with more convenient *Aliment*. Because *Fish*, as *GALENI* observes, generates a thinner *Blood*, and more *Excrementitious*, than the *flesh* of *Terrestrial Animals*.

So likewise from the *Qualities* of *Aliments*, remaining in the *Body* of *Man*, many *Diseases* are generated; as the *Scurvy*, the *Gout*, &c. Thus we find that the *Scurvy* is an *Epidemical Disease* in those Countries, where they eat *Meat* much salted, and dried in the *Smoke*, and brew their *Beer* of *Brackish Water*. And those are commonly troubled with the *Gout*, who live intemperately and luxuriously, especially if they feed much upon *salt Meats*, and drink much *Wine*. For as the Learned *Dr. WILLIS* observes in his *Pathologia Morborum*, by this means a raw and indigested *Chyle* is prepared; and then, by the intemperate drinking of *Wine*, those *Saline Dregs*, which otherwise would go to the *Excrement*, and be carried forth with them, being too much exalted, are conveyed into the *Blood*. To which *Enormities* of *Diet*, if a *Sedentary Life*, *Idleness*, and *Sleeping* after *Dinner* do concur, whereby those *Superfluities* are hindered from exhaling, or being discurr'd by *Labour* and *Exercise*, they will the more certainly produce the *Gout*, and that in the worst manner.

CHAP. VII.

Living things do vary and alter, according to the difference of Place and Time.

I. What the Alteration or Change of Bodies imports.

A Body is said to be alter'd, when it suffers any change in the figures of its *Sensible* or *Insensible parts*; or when it loseth some *Parts*, and acquires others. Thus a *bruised Apple* is said to be changed or alter'd, because many of its *parts* have acquired another *Position*; and some of them may have quite changed their former *figures*. This *Alteration* is caused two several ways in *Living Bodies*; either by being removed from one place to another, as from a *hot* to a *cold Country*; or on the contrary; or by the different *Seasons* of the *Year*, which is the diversity of *Time*.

II. The Difference of

Living things, that are removed from one Country to another, are by this means variously

altered, being sometimes meliorated, and sometimes again degenerating, as the *Climat* doth agree, or disagree with them. And this, because of the difference of *Heat* and *Cold*, *Moisture* and *Dryness*, that predominates in those Countries; for according as the *Climat* or *Soil* of any Country differs, so the disposition of those Bodies that are there differ also. Thus some *Plants* grow much taller and fairer in some Countries and Soils, than in others. Some *Plants*, being removed to a better *Air* and *Soil*, are thereby meliorated and bring forth wholesome *Fruits*; whereas in their *Native Soil*, they brought forth deadly and poisonous *Fruits*. As *COLUMELLA* acquaints us with a certain *Plant*, which by being removed from *Persia* to *Egypt*, loseth its venomous *Quality*, and becomes wholesome to those that eat it.

Thus *Herbs* that grow in *Barren Grounds*, are very different from those that grow in a rich and fat *Soil*, which are far more large and fair, than the former. Thus *Bugloss*, *Comfrey* and *Avens*, change the colour of their *Flowers* by the Industry of *Gardeners*, and the Fruitfulness of the *Soil* where they are planted. *Violets* also, whose *Natural colour* is *Purple*, are changed into a *Blaw*, when they grow in rich *Ground*. In like manner, some *Plants*, that are armed with *Thorns* and *Prickles*, being transplanted to some certain places, lose much of their *Prickliness*.

And on the contrary, *Plants*, removed from a fat and rich *Ground*, to a dry and *Barren place*, do frequently degenerate. So we find that the *Plants* brought from the *Canary Islands*, and other hot Countries, if they be planted in our *Northern Climat*, lose much of their genuine *Virtue* and excellence; as we see in the *Herb* called *Masterwort*, which tho' it retain the same outward shape and appearance, yet differs very much in force and virtue, from what it is in those hotter Countries. Yea, it is reported by some, that the *Earth* brought from the *Fortunate Islands*, and other far distant Countries, into *Italy*, hath brought forth several strange *Plants*, different from those that grow in *Europe*.

All kinds of *Plants* affect some particular *Climat* and *Soil*, and especially those places where they sprung up at first, whence they cannot be removed without danger of being prejudiced thereby. For some love shady and moist places; others, high grounds, and expos'd to the *Sun*; some delight in *moorish* and *fenny Ground*, others in *dry* and *sandy*; which, if they be removed from these places, lose much of their *virtue* and *fairness*. Those which delight in hot Countries, will not grow in those that lye far North; neither will those that thrive in cold Countries, live under the *Terrid Zone*. Thus *Wormwood* grows plentifully in *Pontus*; *Orris*, in *Dalmatia*; *Hellebore*, in the *Island Anticyra*; *Sea Purslan*, on the *Sea Shore*. *VIRGIL*, in the Second Book of his *Georgicks*, does elegantly set this forth:

All Grounds not all things bear, the Alder-Tree grows in the Fens; so with Sallows Brooks agree: Ash, craggy Mountains; Shoars sweet Myrtle fills; And lastly, Bacchus loves the Sunny Hills.

Countries, contribute to the variety of things.

III. Herbs vary according to the diversity of the Soil or Country where they grow.

IV. Plants degenerate, when transplanted from a fruitful Soil, to a barren.

V. All Plants have particular places which they delight in.

VI.
Those that
thrive in
Hot Coun-
tries, com-
monly dye
in Cold
Countries.

For the Plants that thrive in *Arabia*, the *East* or *West Indies*, *Brazile*, &c. being transported to *France*, *Flanders*, or *Germany*, do not grow there without great Pains-taking, and after all do not answer the *Virtues* of those that grow in those hotter Countries. Yea, the curious lovers of Plants, when they transplant any *Herbs* or *Trees*, take diligent observation of their standing in the places where they Naturally grew, what part of them was turned towards the *Pole*, &c. that they may set it again in the very same manner as it stood before; because they suppose that the change of their former situation may very much hinder the thriving of them, and spoil the inward disposition of their Parts. See the *History of Nature*, concerning Plants, Chap. VI.

VII.
Change of
Place is
the Cause
of Altera-
tion in
Animals
also.

Much a like Alteration we shall also find in *Animals* that are transported from one place to another. For we find that *Youths*, upon any considerable changing of the *Air* wherein they were born, do shoot up strangely in a few Months time, more than they would have done, had they continued at home in several Years. Others again, upon changing of their *Native Soil*, do grow thin and meager, and lose their fresh and lively colour. It is also notorious, that some persons have an Antipathy against some places, because that where they were born is of a quite opposite Temperament.

VIII.
Difference
of Time
and Sea-
son, is the
Cause also
of altera-
tion in
Living
Bodies.

Neither doth the Difference of *Time* occasion a less change in *Living things*, than that of *Place*. For tho' Plants be nourished all the Year through, yet do not they always shew forth the same effects of their *Nourishment*; for during *Winter* they are divested of their *Leaves* and *Seeds*, excepting only some few, viz. the *Bay-tree*, the *Yew*, the *Ivy-bush*, &c. which by reason of the clammy Juice where with they are nourished, do not shed their *Leaves*, as the rest do. Accordingly also Care is taken, that such *Seeds* which can endure the *Frosts* of *Winter*, be sown in *Autumn*; and others again at the beginning of *Spring*, or a little before the *Humour* begins to move, lest by the too abundant affluence of it, the *Roots* should perish. For as some *Seeds* are spoiled for want of *Moisture*, so others perish by an overplus of it. *Fruits* also are subject to *Alteration*, according to the several *Seasons* of the Year, most of which are only green in *Summer*, but attain perfect maturity in *Autumn*, and losing their former taste, smell, and colour, do acquire new *Qualities*, and accordingly affect our *Senses*.

CHAP. VIII.

Of Plants; and first of all of their several Parts.

I.
The Parts
of Plants
are either
Simple or
Compound.

HAVING hitherto spoke of *Living Bodies* in General, we come now to the handling of Plants in Particular, to the end that having explained their *Nature*, what we have to say concerning *Animals* may be the more readily understood. The first thing to be considered in *Plants*, is their Parts, which are either *Simple* or *Compound*. I call those *Simple parts*, which consist of *Particles* of the same Texture and Constitution; such as are the *Juices* or *Liquors* contained in them. The *Compound parts* are those that are made up of parts

of a different Nature; and are also called *Organical parts*, because they concur to some one *Action* or other; as the *Root*, *Stalk*, *Leaves*, *Flowers*, &c. Some whereof are *Perficient* and *Integral*; others *Conservative* of the kind; others *Ornamental*, and others *Defensive*. The Parts belonging to the completing and perfecting of a *Plant*, are the *Root*, and *Stem* or *Stalk*; those that concur to the propagating of their kind, are the *Fruit* and *Seed*; and those that defend them from the Injuries of the weather, and otherwise, are the *Bark* Thorns, or *Prickles*, *Shells*.

The *Simple* or *Similar parts* are the *Juice*, or *Moisture*, the *Nerves*, the *Windpipe*, and the *Flesh* of *Plants*.

The *Juice* or *Moisture*, is the liquid part of a *Plant*, diffused through the substance of it. This Juice is, as it were, the *Blood* of the *Plant*, which if it chance to burst through any part of it, whether of its own accord, or by the heat of the *Sun*, or by cutting or lopping of the *Plant*, is called a *Tear*, because it breaks out of the *Tree* like a *Tear*, or *Drop*. Which *Drops* are twofold: The first are such as are of a *Watry Nature*, having something of an *Earthy* consistence joyn'd with them, and are called *Gum*; which is that congealed and thick *Liquor*, that proceeds from the *Trunks* of *Trees*, and cleaves to the *Barks* of them; and the other more oily and fat, which is called *Rosin*.

Nerves in a *Plant*, are those fibres or strings, which give consistence and strength to the softer Parts of a *Plant*; and by which the *Alimentary Juice* ascends. The *Spirit* contracts the fibre or string, and so drives the *Moisture* upwards, which descends through the little *Bougets* or *Membranous passages*. For in every *Plant*, besides the *Sensible Body*, there is a *Subtil vigorous Body*, the *Producer of Motion*, viz. the *Spirit*, which runs through the whole *Body* of it.

The *Trachea* or *Wind-pipe* of a *Plant*, being also a *Similar part*, is an open and wide *Vessel*, consisting of little thin *Plates*, ranged like the *Scales* of a *Fish*, or writhen and twisted together, being for the most part of a *Silver colour*; and may be easily stretched, prest and bent. In the *Trunk* or *Stem* of a *Tree* they run upwards; in the *Leaves* they are made like a *Net*, and take up great Spaces in them; in the *Sprouts*, *Buds*, and *Shoots* they are twisted, and are called by a Learned Man, *Vasa spiralia*, *Spiral Vessels*.

The *Flesh* is another *Similar part* of a *Plant*, which is thick, but somewhat soft, and is outwardly cover'd with the *Bark*: Of which hereafter.

The *Compound*, or *Dissimilar parts* of a *Plant* chiefly, are the *Root*, the *Stem* or *Stalk*, the *Bark*, the *Pith*, the *Branches*, *Leaves*, *Flowers*, and *Fruits*.

The *Root* is the lowest part of a *Plant*, sticking in the ground, through the passages and pores whereof the *Alimentary Juice*, being moved by *Heat*, is driven upwards. This Part is so necessary to *Plants*, that none can subsist without it. There is one kind of the *Herb* called *Chamaeleon*, which wants a *stalk*; *Wheat* hath never a *branch*; the *Fig-tree* hath no *flowers*, *Jesamin* hath no *fruit*; but there is no *Plant* without a *Root*; nay, there are some that are nothing else but a *Root*, viz.

II.
The Simple
parts of a
Plant.

III.
The Juice or
Moisture.

IV.
The Nerves
or Sinews.

V.
The Wind-
Pipe.

VI.
The Flesh.

VII.
The Compound
Parts.

VIII.
What the
Root is.

viz. a *Mushroom*. For the *Root* is, as it were, the *Mouth* by which the *nourishment* is taken in, or like the *Hand* by which *Plants* draw *Juice* out of the *Earth*, and send it up into the *Trunk* or *Stem*. And to this end it is *porous*, and full of many loose *passages* for the *humour* freely to ascend that nourisheth the *Plant*. The *Roots* are very different in their *Figures*, so that almost every different kind hath *Roots* of a different *figure*. In a *Fig Tree* and *Olive Tree* the *Root* is single, and sinks very deep, yet sends forth several little *twigs* from the sides of it. In *Leeks* and *Onions* the *Roots* are manifold, as consisting of innumerable *threads* or *Hairs*; in *Turneps* it is *Round*; in *Beets* it is without *Joints*; in *Orris* it is full of *Joints*; sometimes it consists of many round *knots*, as in *Birchwort*. Yet all *Roots* generally agree in this, that they end in a *Cone*, or sharp point; for the upper part of the *Root*, drawing to it self more *Aliment*, doth grow to a greater bulk than the lower part.

IX. The *Stock*, *Trunk* or *Stalk* is that part of a *Plant*, which riseth up from the *Root* above the *Earth*, and transmits the *Moisture* it receives from it to the utmost parts of it. In *Herbs* it is properly called the *Stalk*; when it is hollow, it is called *Calamus* the *Reed*, and in *Corn Culmus*, the *Blade* or *Straw*, and in *Pulse Scapus*, the *Shaft*. The *Stock* or *Stem* of a *Plant*, before it be turned in to *wood*, consists of a *spongy substance*, somewhat soft, and full of a coagulated *Juice*, from the abundance whereof its *Green Colour* proceedeth. If the top of it chance to fall off, it grows so much the thicker, because then it enjoys that part of the *Aliment* which was appointed for the *nourishment* of the top, and thereupon dilates its self and grows bigger in bulk. It is common to the *Trunks* of *Plants* to become *crooked*, and to bend one way, when the *ground* begins to be dry and *sapless*, and furnisheth a more hard *Alimental Matter*, than can be well digested by the *Tree*. Tho' the *Stocks* of *Plants* be generally *Cylindrical*, yet there are some that are corner'd: In *Daffodils* the *Stalk* is two-corner'd; in *Cyperus*, which is a kind of *Rush*, it is three-corner'd; and in *Horebound* the *Stalk* is 4 square.

X. The *Bark* is, as it were, the *Skin* or *Hide* wherewith the *Plant* is cover'd; and the same is manifold in one and the same *Plant*, *viz.* the outward, which resembles the *Cuticle* or thin outward *Skin* in *Man*; the middlemost which is thicker like a *Hide*; and the inmost which is like a thin *Membran*. And therefore the *Bark* is reckon'd amongst the *Dissimilar Parts* of a *Plant*, because it consists of a great variety of *Strings* and *Fibres*, and of several *Coats*. For it is not the same in all *Plants*; for in some it is thick, as in the *Poplar Tree*; in others thin, as in the *Bay Tree*; in a *Reed* it is like a *Membrane*; in a *Vine Nervous* or *Sinewy*. In the *Spring* time the *Bark* is with ease separated from the *Tree*, because of the *Juice* that ascends between it and the *Tree*, which dissolves that *Glew* whereby it was before fastned to the *wood* of it.

XI. The *Pith* of a *Plant*, which by way of excellence is called the *Heart*, *Brain* and *Matrix*, is that middle part whereby the *Aliment* is conveyed from the *Root* to the upper parts. The same is also very different; for in some *Plants* it is soft and spongy, as in the *Elder Tree*, where it

resembles *froth*; in others again it is harder, as in the *Pine Tree*, whose *Pith* is *woody*. The *seminal virtue* of the *Plant* is suppos'd to be lodg'd in the *Pith*, forasmuch as not only the *Branches*, but the *Fruit* and *Seed* are derived from it.

The *Branches* are the upper parts of a *Plant* which spread themselves from the *Stalk* or the *Trunk* of a *Tree*, as so many *Arms* stretched forth, to which they are joined by a *glutinous substance* hardned, which they call *Nodus* or a *Knot*, and in their sprouting forth from the *Trunk* make an *Angle*, which in *Latin* is called *Sinus*, resembling the *Arm-pit*, or the joining of the *Arm* to the *Body*. In many *Trees* the *Branches* grow without any order, but in the *Pitch* and *Fir Tree* they appear in a curious and beautiful ranging; the thinner and utmost parts of the *Branches* are called *Sprigs*, which are more tender than the rest of the *Branch*, having not long been expos'd to the intemperature of the *Air* or *Weather*. The swellings that appear in the *Joints* of them, are called *Buds*, as long as they continue round, and are not yet open'd. And the thin tops of the *Sprigs* are called *Sprouts*.

Leaves are the ornament of *Plants*, and the coverings of the *Flowers* and *Fruit*, shading them from the *Heat*, and defending them from the intemperature of the *Weather* or *Air*. They generally proceed from the more thin and tender part of the *Bark*: so that when the *Bark* is pluck'd from a *Bough*, we find that the *Leaves* stick to it, and are pull'd off together with it. Yea, if the whole hollow of the *Bark* be pull'd off from a *Branch*, and the lower part of it be put into *water*, in the *Spring* time, *Leaves* will sprout forth from the upper part of it. The *Figure* of *Leaves* is manifold; for in some *Plants* they are large and broad, as in a *Gourd*; in others very small, as in a *Pine Tree*; in some thick and fleshy, as in *Purslain*; in others nervous and full of *Sinews*, as in *Wheat*; in *Onions* they are hollow like a *Pipe*; in *Aloes* partly round, and partly angulous. The *Stalk* or *Stele* of *Leaves* is also various; in those of an *Olive Tree* it is short; that of *Vine Leaves* is somewhat long; in *Colts-foot* and *Herbs* that grow in *Ponds*, the *Stele* of the *Leaves* is very long, because in them it is instead of a *Stem* or *Stalk*. Sometimes only one *Leaf* grows upon one *Stele*, as in the *Poplar* and most other *Trees*, sometimes more, whence those *Plants* are called 3 leav'd, 5 leav'd, 7 leav'd.

Flowers which are the most beautiful product of *sporting Nature*, do greatly conduce to the Ornament of a *Plant*. They consist of a four-fold substance, or rather of so many parts, *viz.* of the *Knot* or *Cup*, the *Leaves*, the *Threads* or *Thongs*, and the *Stalk* or *Stele*.

The *Knot* or *Cup* is that part which covers the *Flower* and keeps the parts of it together; as being the *Base* and support of it; and therefore is of thicker and stronger substance, and not so beautiful as the *Flower* it self.

The *Leaves* of the *Flower* compose the *Body*, and Beauty of the *Flower* it self, being remarkable for their *Indure*, but very fading, and of a very tender Complexion and Texture.

The *Threads* are those long and slender parts in the middle or *Navel* of a *Flower* like *Hairs* or *Threads*, which in some *Flowers* are thicker than

XII.
The Branches.

XIII.
The Leaves.

XIV.
The Flowers.

in others, and often have little Spires at the top of them; and are set round about the *Stele*, which is a long, but thicker part of a *Flower*, rising up from the middle of the *Navel* of it.

The *Stele* is the middlemost part of the *Flower*, sticking to the Rudiment of the *Fruit* or *Seed*. It is called in Latin *Stylus*, because of its being thin and long. All these parts are very distinguishable in a *Rose* and *Lilly*.

XV.
The Diversity of Flowers.

Some *Flowers* want a *Stele*, as those that grow upon the *Bay Tree*; some instead thereof have a *Stalk*, as *Saffron*. All others generally have a *Stele*, as appears in the *Apple Tree* and in a *Rose*. But more particularly they differ in colour, which in a *Violet*, is Purple; in a *Marygold*, Yellow; in a *Blue-Bottle*, Blue; in a *Lilly*, White; and in a *Rose* various, there being *Red-Roses*, *Damask-Roses*, *White-Roses* and partly colour'd. Neither do *Flowers* less differ by their *Smell*. And what is worth our consideration, we find a most grateful odor in a *Rose*, and none at all in the *Plant* whence it grows; whereas in *Sage*, the *Flower* is without any *smell*, tho' the *Herb* itself be very odorous: In *Borage* we perceive both *Plant* and *Flower* destitute of any *scent*; whereas in *Lavender* both the one and the other are odiferous.

XVI.
The Fruit.

The *Fruit* as it includes the *Seed*, and *Flesh* or *Pulp* of the *Fruit*, is the last work, and, as it were, the Masterpiece of the *Plant*; and to the producing whereof all the other parts of the *Plant* do concur. Its *Fashion* or *Figure* is various; some are partly of a *Conical* figure, as *Pears*; others of a solid *Elliptick* figure, as *Olives*, *Plums*, &c. some are *Round*, but somewhat flattened at both ends, as *Apples*; some perfectly *Round*, as *Cherries*, *Grapes*, *Berries*, *Correns*. They have also different *Coverings*; for *Wheat* is cover'd with a single *Membran*; a *Chestnut* with a thick *Skin* full of *Prickles*; an *Acorn* with a scaly *Shell* or *Cup*; *Almonds* and *Walnuts* inwardly with a hard *Shell*, and outwardly with a green *Shell* or *covering*.

XVII.
How Plants are said to bring forth their Fruits.

Plants are said to bring forth, when they bloom or flourish, and when the *Flowers* break forth from the *Knops* or *Buds*; but the *Education* or *Rearing* of their Off-spring is in the *Fruit*, for the sake whereof a *Plant* grows, and is therefore call'd the *Mother* and *Nurse* of her *Fruits*.

XVIII.
Whether Leaves, Fruits and Flowers be the true Parts of a Plant.

It hath been a long controverted *Question* amongst the *Ancients*, whether *Leaves*, *Flowers*, and *Fruits*, were to be accounted parts of a *Plant*. *THEOPHRASTUS* seems inclin'd to the negative, as supposing them to be no more the parts of a *Plant* than the *Births* of *Animals* are any part of them; for they being after a certain term separated from their *Parents*, cannot after that properly be called *Parts* of them. But this Controversie seems only to be about words: for if *Leaves* may not be accounted as the *Parts* of those *Trees*, whence they are yearly separated at the *Fall*, as in the *Oak*, *Walnut-tree*, &c. why may not they as well be denied to the *Pine*, *Olive Tree* and such others which never are without *Leaves*, seeing that those *Trees* also lose their *Leaves*, tho' not altogether, but by a continual succession of new ones, shooting out in the room of the old ones. Therefore those who account only that to be a part of a *Plant* which always continues with it, have good

reason to bar *Leaves* of that Privilege; for otherwise I see no reason, but they may well enough be admitted to be parts of a *Plant*.

CHAP. IX.

Of the Original of Plants.

IT cannot be questioned, but that in the Beginning of the *World* there was a Power communicated to the *Earth* of producing *Plants*, and that great variety of *Vegetables* that are found in all *Countries*. In the first Chapter of *Genesis* we find these words, Let the *Earth* bring forth Grass, the *Herb* yielding *Seed*, and the *Fruit-Tree* yielding *Fruit* after its kind, whose *Seed* is in it self after his kind. Now this virtue imparted to the *Earth* continues still in its full vigor, neither doth any thing spring out of the *Earth*, but by this virtue. But forasmuch as many *Vegetables* seem to spring of themselves, whereas others are manifestly beholden to *Root* or *Seed*, for their *Growth* or *Production*; we are to enquire how this twofold *Production* is performed, and how it comes to pass that some spring as of themselves, whereas others stand in need of a manifest *Seed* for their *Production*.

Those *Plants* are said to spring of themselves, which the *Earth* produceth without the sowing of *Seed*, and to grow by accident, as the *Schools* express it. Such as are *Purslain*, *Houfseek*, *Pennyroyal*, &c. which, as some tell us, do of themselves grow out of the *Earth* that is dug up, in a shady and moist *Wood*, being put into *Earthen Pots*. *PORTA* tells us, lib. 2. *Phyt. cap. 1.* that having exposed some *Earth* that had been dug up from the deepest foundations of a *House*, to the *Air*, within a few days, several kinds of *Herbs* sprung up from it, familiar to the *Soil* and *Climat* of *Naples*. And the famous *Lord VERULAM* assures us, that the *Earth* dug up from the foundations of *Houses*, or from the bottom of *Wells*, being put into *Pots*, will after a few season produce several sorts of *Herbs*. For if you take up *Earth* not above an *Ell* deep, it will be fruitful the first year; but if you take up that which lies deeper, it will not produce any thing till after a years time, and sometimes 2 years.

Some *Philosophers* are of opinion, that such *Plants* as these are produced without any *Seeds* at all, and that the *Earth* produceth them by an innate virtue of their own. But that which hinders me from assenting to this opinion is, because I find that all *Countries* do not produce the same *Plants*; which could not so happen if there were not diverse dispositions in them, proper for their several *Productions*. But what can these different *Dispositions* be, but *Seeds*; or those first *Buds* from whence *Plants* arise? For what else doth the *Sun* do, when it cheriseth the *Earth* with its heat, mixeth it with *Water*, exhales the moisture from it, dries the *Particles* of it, &c. but work such dispositions in the *Earth*, and so fit the insensible parts of it, as that from the due ranging of them, the *Roots* of *Plants*, their *Strings*, *Ribs* and *Veins* are formed, through which their *Aliment* may be conveyed, and being sufficiently prepared, break forth in the other parts of it?

I. There is Virtue in the Earth, whereby it is impowered to bring forth Plants.

II. What those Plants are that grow of themselves.

III. The Plants which are said to grow of themselves, owe their Rise to Seeds.

IV.
What are
the Seeds
of Plants,
that are
said to
grow of
themselves.

The Seeds therefore of these Plants, are those *Insensible Particles*, which by the agitation of the *Subtil matter* do obtain such a *situation, figure, and motion*, as are needful to form the first Rudiment of a Plant. And forasmuch as this *disposition of parts* is not to be found in all Parts of the *Earth* alike; therefore it is no wonder, that all Plants grow not in all *Countries*. We are to take Notice also, that there is no difference betwixt these kind of *Seeds*, and those which are the Product of *Plants*; save only this, that the Parts of these latter are more closely compacted together, and more orderly framed: Whereas those which arise from the various *Motion, Spreading, Mixture, and Composition* of concurring *Particles*, are not so exactly joyn'd and formed, and therefore *Plants* are more slowly produc'd by them.

V.
The first
Trees were
produc'd
without
Seed.

Some Authors relate as Miracles, that sometimes tall *Trees*, yea, whole *Woods*, have sprung out of the *Earth*, without *Seeds*: But they did not consider, that vast store of *Seeds*, which are hid in the *Earth*, and are the beginnings and first Draughts of those *Seeds* that are the products of *Herbs and Trees*. THEOPHRASTUS observes, 2. *Histor. 2.* that the *Earth* in *Crete*, presently after it was dig'd up, did bring forth *Cypress Trees*, which are also propagated by *Slips*. Can any one believe, that the first *Trees* were the product of *Seeds* fallen from *Trees*? Or, that the *Great Woods* that are found up and down, were sown by *Men*? For seeing that the *World* had a Beginning, and that we cannot admit a progress to Infinite, we must come at last to those *Trees* which had no such *Seeds*, whence they were produc'd, and for the production whereof the Nature of the *Climat* and *Soil* were sufficient. For *Cinnamon, Myrrh, Frankinsence, and Cassia*, did always abound in *Southern Countries*; as the *Northern Grounds* never wanted *Willows, Oaks, Fir-trees, Elms, &c.* which delight most in those places, and will not without care and difficulty grow elsewhere. According to that of *Virgil*:
The blackest Ebony from India comes,
And from Sabæa Aromatick Gums.

VI.
Calcin'd
Earth pro-
duceth
great abun-
dance of
Plants.

Some observe, that *Earth* that is burnt or calcin'd, when expos'd to the *Air* and water'd with plentiful *Showrs*, doth immediately bring forth great store of *Vegetables*; because the *Pores* of the *Earth* being opened by this means, the *Seeds* are set free from their *Prisons*, and meeting together are entangled, and so constitute little *Masses*, from whence those *Plants* proceed. It is a thing very notorious, that in *Walks* that are thick overspread with *Sand*, the *Earth* the first Year produceth only knotted *Grass*, and the following Years a thick and swoln *Grass*, like the blade of *Corn*; because the hardness of the *Sand* or *Gravel* hath hinder'd the due coagulation of the *Seeds*; but as the surface of the *Earth* comes to be more freed from the *Sand*, the *Seeds* can the better come together, and thus produce common *Grass*; to which *Showrs* do very much contribute, by moistning the *Earth*, and thereby setting the *Seeds* that are in it more at liberty.

VII.
How Plants
are pro-
duc'd from

As to *Plants* that are sown by *Men*, the Explication of their way of Production is not difficult. For when, by Example, a *Pea* or *Bean* is put into

the *Earth*, and there meets with a due moisture and moderate heat, it first begins to swell, and distends its *Skin* or *Husk*, and having at last broke it, the same Causes continuing, do afford it new *Matter*, and the first beginning of the *Plant*, which we call the *Bud*, appears; which by thin *Fibres* or *Strings*, spreading it self through the pores of the *Earth*, and the Parts of it pressing upon it, must needs grow hard; and thus is the *Root* of the *Plant* formed. The *Matter* being thus digested into a *Root*, being recruited by new Incoms of *Heat*, and dilated by the same mounting upwards, the tender and green *Substance*, which is commonly call'd the *Leaf* or *Bud*, riseth and springs up; which still growing higher, turns to a *Stalk*: For a purer *Juice* being now duly prepared in the *Roots*, doth by degrees ascend from thence into the *Stalk*, which Motion upwards is much promoted by the pores of the *woody Stalk* or *Stem*. Moreover, *Heat* being active and impatient of Idleness, continually drives the moisture or *Juice* upwards; and so the *Stalk* becomes extended, and riseth to a considerable height. Now when the *Juice* doth not ascend so fast, and that the parts of it, by the agitation of *Heat* are more depurated, they are by the driving of the *Fire* carried above the *Stalk*, where meeting with the cold *Air*, they are stopt from mounting any higher; where still more particles of the said *Juice* joyning them, they swell into a *Bud*. And whereas the affluence of *Heat* through the *Stalk* still continues, is burst open, or splits the *Bud*, and by this means makes way for the *Subtil matter* to break forth, and display it self in the appearance of a beautiful *Flower*. And lastly, after that the *Alimentary Juice* hath still attain'd a further degree of Perfection, another *Substance* succeeds in the room of the *Flower*, which being hollow within, contains the *Fruit*, that is, the *Pea* or *Bean*, and is a defence to it, against the Injuries of the *Air*. For in all *Natural things* there is, as it were a kind of *Circle*, whilst the *Seed* of the *Plant*, under a different respect, is called the *Antecedent Principle*; and the *Fruit* the *Consequent*.

CHAP. X.

Of the Nourishment, and Growth or Increase of Plants.

HAVING spoken of the Forming of Plants, we now proceed to Treat of their Nourishment, which seems to be nothing else but a continued Generation; because all the Parts of that which is generated would fall away immediately and waste, without the supply of food, that preserves them from perishing. The Nutrition of a Plant therefore is the distribution of the inwardly received, and altered Aliment, into all the Parts of it; and the transmutation of it into their Substance, for the supply of what continually wastes and evaporates by the force of Heat. For the Moist parts of Plants, as well as Animals, are in a continual flowing, as is manifest from the Leaves and Flowers that are pluck'd off from them; for these immediately grow limber and wither, by the want of that Juice, which used to distend their Vessels and Bladders.

III. Not that *Plants* make use of choice in attracting of their *Aliment*, so as to take in that which is agreeable to them, and reject the contrary; forasmuch as no such attraction can be found in *Natural things*: But we must rather conclude, that the pores of the *Roots* are of such a figure, as are fit to admit those particles that are proper to nourish the *Plant*, and exclude the rest; after the same manner as the *Liver*, by transmitting the *Gall*, and the *Kidneys* the *Urine*, do thereby separate them from the *Blood*.

IV. This will be still more manifest, if we suppose 2 things in *Plants*, viz. *Heat* and *Pores*, which are the Instruments of *Nutrition*: For by *Heat* the *Alimentary Juice* is driven upwards; not only from the *Earth* into the *Root*, but also into the *Trunk*, *Branches*, and the utmost *Leaves*: And in this its passage the *Nourishment* is further concocted, prepared, distributed and coagulated, so as to be fit for the *Aliment* of *Plants*. For in every *Plant* or *Vegetable* there is something, which with respect to the *Earth* whence they grow, has the Nature of a ferment.

V. If you demand, whence this *Heat* proceeds; and what that Agent is which begets a fire in *Plants*? I answer, That the primary Cause of this *Heat* is the *Sun*, whose *Rays* in the *Summer* time do continually beat upon the *Earth*, and the *Plants* that grow out of it: Neither is the *Earth* in the *Night*, or during the *Winter*, altogether destitute of *Heat*, but preserves always some portion of warmth communicated to her by the *Sun*, whereby she fosters the *Plants* in her Bowels, and assists their *Nutrition*. Tho' it cannot be deny'd, but that sometimes this heat in *Plants* is owing to *Subterraneous*, or any other fires: As we find that *Aloes*, *Onions*, the *Roots* of *Saffron* and *Leeks* will grow, being hung up in *Rooms*, especially where constant fires are kept.

VI. Pores likewise are of great use to the *Nutrition* and Increase of *Plants*, since they are the passages by which the *Juice* is received, and through which it is distributed to all the Parts of the *Plant*. For as the *Lacteal Veins*, and the *Subclavial Branches* of the *Vena Cava*, are necessary for the receiving of the *Aliment*, and the conveying of it from one part of the *Body* to another; so likewise there are found in *Plants* innumerable Passages and Channels; like to the *Lacteal Veins* in *Animals*, by which the *Juice* is transmitted from the *Root*, to the utmost parts. For such is the disposition of Pores in *Vegetables*, that the *Aliment* is much more conveniently transmitted by them, than it could be through the free and open *Air*; for by this means the dissipation of the *Alimental Juice* is prevented, and its motion is more ready and without interruption: As we find that *Bullets* move more readily through *Pipes*, and *Smoke* through the *Funnel* of a *Chimney*, than in the open *Air*. And hence it proceeds, that *Plants* that have been often sown, are thereby more exhausted, than those that lie fallow.

VII. These things being understood, it will be no longer difficult to conceive, how the *Nutrition* of *Plants* is performed, and how they are increased; for *Vegetables* are nourished whilst the *Juice* is by the *Sun*, and the rest of the *Subtil matter*, driven into the pores of the *Root*, and being there prepared by Concoction, after it hath past several

strainings, doth spread it self in length, breadth, and depth. The softness also or tenderness of the *Sprout* or *Sprig*, doth much further the conveyance of the *Nourishment*; because it makes the *Pores* to be easily widened and distended. For as we find that the pores of *Bread*, being dipt in *Wine* or *Water*, become immediately distended thereby; so likewise the *Alimentary Juice*, when driven into the little Channels of *Vegetables*, doth open and extend them: Which doth not happen so in a dead or wither'd *Plant*; because in it the parts of the *Pores*, and small threads or fibres, are otherwise disposed, so as not to be able to admit the *Juice*, which the *Subtil matter* hath driven into the *Roots*.

The *Aliment* of *Plants* must be *Liquid*, because it would not be fit to be carried upwards, or strained, in case it were dry or hard. Yet is not this *Juice* a moisture destitute of all Clammy-fatness of the *Earth*: For seeing that the parts of a *Plant* must stick and grow together, and that this cannot be without the entanglement of *Heterogeneous particles*; it is evident, that *Water* alone cannot be a fit *Aliment* for *Plants*, except it be well temper'd, with a sufficient proportion of the Slimy-fatness of the *Earth*. And accordingly we find, that *Waters* in which *Salt* is dissolved, or mingled with some Fat matter, are most proper for this effect, and make the *Vegetables* that are watred therewith, to thrive mainly. And it is for the same Reason, that *Countrymen* do recruit their barren Grounds with *Dung*, *Marle*, and the like. For *Water* alone too swiftly penetrates the Parts of *Vegetables*, nor stays long enough with them, so as to become their *Aliment*.

Tho' the *Aliment* of all *Plants* be Moisture, temper'd with the Fatness of the *Earth*; yet is not every such mixture fit Nourishment for every *Plant*. For as *Vegetables* affect particular places; some delighting in shady and low *Valleys*, others in high and upland Grounds; some in dry and sandy, and others in moist Ground; some in a fat and rich Soil, and others in a barren and hungry: So accordingly do they stand in need of a different Nourishment, which when ever they miss of, they soon languish. For the Particles of these *Juices* being various, they must needs constitute different *Liquors*, whereof those only are a fit Nourishment for such and such a *Plant*, which have an affinity with it, by the suitableness of the configuration of their Parts. Thus it is observed, that those *Roses* smell sweeter, that have *Garlick* growing near them; because the particles proper to produce a strong and ungrateful Scent, are taken in by the *Garlick*: So that few or none of them can come to the *Rose*, to allay or diminish the sweetness of its Odour.

The stocks or stems of *Trees* and *Shrubs*, with the *Branches* proceeding from them, are every year increased by new woody accessions; forasmuch as every year, a new round of *Fibres* is added to the inward *Bark* or *Rind*; which being divided in two parts, the outward part of it is added to the *Bark*, and the Inward part growing harder and harder, before the end of *Autumn*, acquires the compactness of wood, and separating it self from the *Bark*, becomes joyned to the *Wood*, and so increaseth the *Trunk* or *Stock* of the *Tree*. But tho' we find, that the *Trunks* and *Branches* of *Trees*

VIII. The Nourishment of *Plants* consists of a Moisture, mingled with the Fatness of the *Earth*.

IX. Different *Plants* require different Nourishment.

X. The Stocks and Branches of *Trees* grow every year.

XIV. The Trunks and Branches of *Trees* are

are encreased this way only, yet must we not conclude from hence, as is commonly believed, that the Juice or Sap of a Tree, mounts upwards only betwixt the Bark and the Wood, but also through those Vessels that lie hid in the Substance of the Wood. This is evident in that the deeper any hole is bored into the Trunk, the Branch or Root of the Tree, the more Juice will distill from it, and that proportionably to the depth of the hole; so that out of a hole that is twice as deep as another, almost a double quantity of Sap will proceed in the same time.

XI. This may be easily understood by the Example of a young Chestnut-tree; for if the Progress of its growth be narrowly observed, we shall find, that after 6 months time, there will be formed in its Bark (which is very thick) 2 rows of woody Fibres; and after 18 months, we shall find 4 of them; and a year after 8, and so on, so that always the last Rows do inclose and involve the former, and make, as it were, a Circle about them, which is surrounded with another Circle, and that again with another; whence it follows, that when the Stem of any Plant is cut across, the Section must appear composed of 2 sorts of Substances, viz. of these Circles, and of insertions that are disposed or ranged in the said Stock, much like Circles of Longitude and Latitude in a Terrestrial Globe.

XII. PLANTS therefore grow or encrease, when greater or more Particles of Alimentary Juice are received by them, than their narrow Pores are able to contain. Hence it is that those Vegetables, the sides of whose Pores are more hard and compact, do not grow so fast as others, whose texture is more loose and open. Thus we find that Peach-trees, Poplars and Willows grow apace, because they have pliable pores, and so crooked and bending, that the Particles of Juice that are driven upwards by the agitation of the subtil matter, can neither advance forward, nor return, and consequently they must enlarge and distend the Plant. And for this reason it is that a Vine, frequently watered, thrives and advances so fast; and that the Chrysanthemum or Marygold of Peru in 6 months time grows 18 or 20 foot high; and by the thickness of its Branches seems to challenge the tallest Trees. But on the contrary, Oaks, Medlars, Box, and Pine-trees grow very slowly, because the compactness of their substance, will not suffer their pores to admit sufficient store of Aliment for their speedy growth and encrease. Thus Golden Maiden-Hair, Whilow-Grass, &c. grow very slow: and for the same reason Trees advance little or nothing in their growth during the Winter Season, because their pores being then shut up by cold, the agitation of heat is not of strength enough to widen them, and to send up the Juice from the Root through them.

XIII. It may be questioned here, how the Alimentary Juice, which is forceably driven into the Pores of a Plant, comes to stay there, without being carried upwards into the Air, or without falling down to the Root again. To which I Answer, that this effect may be assign'd to 2 Causes: the First is a special conformation of the Pores of Plants; for we may suppose that by the continual ascent and percolation of the Alimentary Juice through the pores of

the Plant, many of their small Fibres must be bent in such a manner, as to make the passage rough, by which means, tho' the liquid and fat moisture easily mounts up through them, yet cannot so easily run back again, because of the prominent extremities of the Branchy particles, which oppose their return the same way they entered. Daily experience confirms this, for we find that when with a Knife we cut or scrape a piece of wood with the grain, that is following the natural position of its fibres, we do it with much more ease, than when we attempt the same the contrary way. The other cause is the Winter Frosts, and the coldness of the night, which do fix and condense the Juice conveighed to all the parts of the Plant, and by obstructing the Pores, hinder it from subliming into the Air. For it is certain, that in the Nutrition of Plants, Heat and Cold both act their parts, the one being not sufficient to perform it without the other.

It is to be observed, that as the Blood in Animals, so likewise the nourishing juice in Plants is prepared by a kind of Circulation. For the Juice that is in their Roots or other parts, being tost by a continual motion, cannot thoroughly be dissolved, mingled or strained, without frequently returning to the same part again, and being altered by various impressions. Which Circulation of the Alimentary Juice, depends on the Mechanical Structure of the Fibres, the various disposition whereof performs the same effect, which the Valvulae do in the Veins of Animals; some of them being so formed, that the Juice finds a ready way to mount up between them; and others, so as to afford it an open and free Descent. Which may be proved by several Reasons and Experiments in those Vegetables, which are nourished by a thick Juice resembling Milk.

Mr. MARIOTTE assures us that he hath observed, that upon the cutting off the Tops of Milky Plants, and the parts nearer the Leaves, a greater quantity of Juice hath proceeded from them, than by cutting the parts nearer to the Root. That he experienced this in Celandine; and the structure of Fibres in Spurge, and other Milky Plants persuades the same; for these Fibres by the help of a Microscope appear white, and are nearer unto the Rind, whereas the Juice in the other Fibres is of a more Warry Colour. Whence it seems probable, that the serous Juice, doth mingle with the other thicker, whether Yellow or White, in certain Pipes appointed for that use, much after the same manner as the Chyle entering into the Veins is there mixt with the Blood, and circulates with it. Tho' it be not yet discovered whether this Juice in Plants be carried in the same Pipes from the Branches to the Roots, and again from the Roots to the Branches; or whether distinct Pipes are assigned to these different motions, as the Veins and Arteries in Animals.

CHAP. XI.

Of the Division and Difference of Plants.

A Perfect Plant is by BOTANISTS commonly divided into a Tree, a Shrub, an Undershrub, and an Herb.

I. The Division of Plants.

A Tree

II. *A Tree is a woody Plant, in thickness and height exceeding all the rest, whose stock is lasting, and one only by nature, which spreads it self into many Branches and Boughs, as an Oak, Pear and Fir-tree. I say it is lasting or perpetual, because it hath no certain time of duration.*

III. *A Shrub is a Plant of a mean thickness and height amongst those that are woody, whose Stem is manifold by nature, and which by cutting off its Shoots or Suckers, is easily changed into the nature of a Tree.*

IV. *An Under-shrub is the least of woody Plants in height and thickness, having a lasting Stem or Stalk, which sometimes is single, and sometimes manifold like Brushwood, with a small and slender Leaf, as Rosemary, Lavender, Southernwood, &c.*

V. *An Herb is a Plant which consists only of Leaves, as Harts-tongue, &c. or sometimes of a Stalk, but perisheth away every year, and is not woody till after it be dried.*

VI. *The variety of Plants is assignable either to the Soil whence they grow; or to the Pores or channels through which their Alimentary Juice is conveyed; or to their Structure or Figure; or to the Fruits they bear; or to their differing Qualities, or lastly to the Changes and Alterations to which they are obnoxious.*

VII. *With regard to the place of their growth, some are upon Rocks, Walls, the Tops of Houses, when the water falling in abundance, doth leave some limosity upon those places. Some grow upon other Plants, or upon great Stones; as Moss which grows upon the Barks of Trees; and Touchwood which sticks to the Oaks and Nut-trees. Some proceed from the rotten Wood or Roots of Trees, as SCALIGER tells us, that Bearsfoot doth, Exercitat. 140. Others grow upon Dung-hills, as Sow-thistle, which Hogs delight in, and other such like. Some grow upon the Bodies of Living Creatures, as is related of a Shepherd, who had a little Plum-tree or Sloe-bush growing out of his Breast, because falling by chance upon one of them, he had forgot to pluck out one of the thorns of it which stuck in his Breast, and afterwards sprouted out thence.*

VIII. *Plants are also distinguished by their Pores; for the Alimentary Juice, according to the different structure of the pores it passeth through, acquires a different Temperature and Qualities. According to which different disposition of the Pores, some Plants are more early in their coming forth, and others later. For those that want a Stalk, or have only a short one, are more slowly nourished: others that have a more favourable Texture of their Pores, and the Fibres of whose Stems are more yielding, grow sooner, and to a greater Size and Bulk, especially if the Climate and Soil agree with it. Thus Gourds and Sallows do in a little time encrease to a great Bulk; whereas on the contrary Oaks and Pine-trees, by reason of the straitness of their Pores, are as slow in their advance. And therefore because the Fir-tree, and others of that nature consist of looser and more open Pores than the Ebony-tree, and other-like hard and compact woods brought from Brazile, they are easily bent, but not without difficulty pulled asunder: whereas the parts of these latter are very Brittle and break upon the least bending, because of the very close and compact texture of their Parts. It is also from*

this various disposition of the Pores, that the same Rain furnisheth nourishment to such a vast number of different Plants; because it is changed according to the difference of the Soil, and the variety of the Pores doth diversly affect the said moisture and alter it, so as to become the proper nourishment of such and such a Plant. To which may be added, that the Juice which is drawn from one part of the Earth, doth furnish it with other Alimentary Particles, than another doth.

IX. *But if any one ask, how the Juice ascends from the Root, into the wooden Fibres; they may take this for an Answer, that the Juice ascends in Plants, after the same manner as water mounts up into those Pipes that are made use of in the Experiments of a Vacuum; that is to say, because the weight of the Air drives them upwards. Which effect of the Air is much encreased by the Circular Motion of the Earth, for it being the Property of that Motion, to drive all the most agitated parts far from the Center; accordingly it also drives all the Juices of the Earth into the Pores of the Plants that are more agitated than the Air; whether this their agitation proceed from Subterranean Fires, or from some particular fermentation in the out parts of the Earth.*

X. *A great variety likewise ariseth among Plants from their Structure or Figure; for some are low, as Onions and other creeping Plants. Others grow to a vast Height, as Cedars whose height and thickness is wonderful; Historians mention one that grew in Cyprus to have been 130 foot high, and of that thickness that 3 men could scarcely fathom it. And so likewise the Fir-tree, Abies, which takes it latin name from Abire, that is, to go away, because of the vast height it off riseth to. Historians tell us, that in the Ship, that by command of the Emperour CAJUS brought the Obelisk, placed in the Vatican Circus or Piazza, from Egypt, there was a Fir-tree, whose Trunk was as much as 4 men with their stretched-out-arms could compass. Some grow of a round Figure, as Puffs, others in the form of an Umbrella, as Mushromes. Some have the strings of their Barks extended long-wise, others a-thwart and Cross-wise. Some naturally have crooked Stems or Trunks, as the Vine, others strait and upright, as Reeds and most Trees.*

XI. *Plants are also differenced according to their several Fruits: and thus some are called Glandiferous or Acorn-bearers, as the Beech, the Oak, the Cork-tree and the Chestnut-tree, which latter, for the goodness of its Fruit, excels the rest of the Trees of this sort. Others are Coniferous, bearing a Fruit like a Cone, that is smaller at one end and like a Top; such as is the Cedar-tree, which formerly grew in great abundance upon Mount Libanus, but are reduced to 24 only. So also the Cypress-tree, and the Firr, tho' this is reckoned amongst the Resiniferous or Rosin-yielding Trees. Others are Pomiferous, or Apple-bearers, as the Apple-tree, the Citron-tree, which is always green, of a most fragrant odor, and its fruit of a golden Colour; the Orange and Lemon-tree, the Pomegranate-tree, so called from the great number of grains of Seed which its Fruit doth contain; and the Apricot-tree, whose fruit, from the golden colour, were by the Greeks called Chrysomela or Golden Apples.*

XII. Of Fruit-bearing Trees, some are Nuciferous or Nut-bearers; as the Nut-tree and Almond-tree, which have their Fruit contained in hard Shells; others Bacciferous or Berry-bearers; as the Plum-tree, the Olive-tree, the Mulberry-tree, and the Cherry-tree, which bear a Fruit that consists of a more soft and moist flesh, and cover'd only with a thin Skin: Other Siliquiferous or Pod-bearers; as Cassia, Tamarinds, &c. because their Fruit is contained in Cods or Husks, or in a Juicy-shell, of a longish figure.

XIII. There is also a considerable variety in Plants, from their different Inclinations: For some of them have an Antipathy against others. Thus the Vine, and Cabbage or Coleworts, cannot endure the Neighbourhood of one another; and so likewise the Olive-tree and the Oak, the Bay-tree and the Vine, the Olive-tree and Coleworts, the Nut-tree and the Oak are at variance. Not by reason of any inborn Antipathy, as some do imagine; but because when those Plants stand near together, they rob one another of sufficient Aliment, because they are nourished with one and the same kind of Juice; which being taken in by the stronger and more vigorous Plant, the other must needs languish. And on the contrary, those Plants are said to be friendly to each other, which are nourished by different Juices; so that what is necessary for the Aliment of the one, is never touched by the other. And herein doth the Antipathy and Sympathy of Plants properly consist; according to what we have more largely explained in our History of Nature, concerning Plants. Thus the Fig-tree and Rue thrive in the Neighbourhood of each other, because they delight in a quite different sort of Nourishment; and not by reason of any Consent or Friendship, but by subtraction of the contrary Aliment, which the one draws to feed its sweet-scent, and the other to feed its bitterness. And on the contrary, Rosemary loseth part of its sweetness and savour, when it grows in the Neighbourhood of the Bay-tree or Lavender; because both these Plants delight in the same Alimental Juice, and are like Robbers one to another, whenever they stand close together.

XIV. A Diversity is likewise to be found in Plants that springeth from Transmutation; as when Plants are made more fair and beautiful, by the Art and Industry of Gardiners. Thus that vast variety of Gilly-flowers, proceeds from this Cause. And in like manner there is now the Calatbiana, a kind of Violets, not only of Blew colour, but also White, Red, and of a mixed Colour, by the Curiosity of Ingenious Florists. For the Industry of Gardiners doth conduce much to the variety of Plants; according to what Virgil tells us in his First Book of Georgicks:

*I have seen many would Anoint their Grain,
With Nitre first, then Lees of Oil would spread,
That the Husk swelling might enlarge their Seed;
Then with lent Fire ripen the tender Grain.*

XV. And on the contrary, by the Negligence of Gardiners, or some fault in the Soil, Plants degenerate, and are turned into others not so good as themselves: So Wheat turns to Darnel, Basil into wild Thyme, Barley into Oats, Turneps into Rhabdish, as SENNERTUS assures us; Water-mint

into Spear-mint; the Blak-Vine into Briony, Spelt into Wheat, and Wheat into Spelt. It is also a common Observation, that if the same Seed be for several years together sown in the same Ground, it will degenerate; according to that also of VIRGIL:

*When oft the fairest Barly is sown same Ground
we sow,
Darnel instead thereof, and blasted Oats do
grow.*

The same happens almost to all Plants, when they are transpos'd to different and disagreeing Places: As when Herbs that grow in Pools and Running-water, are removed to the Tops of Hills, or Champion-ground. Thus if the Water-flag should be transplanted to Hilly-ground; or the Seed of Lettice, Cucumber and Cabbage, to a Sandy place: And on the contrary, Heath, Fern and the Thorn-bush, to moist and Marshy-ground; they would soon degenerate to other Plants, and cease to answer to their Names.

CHAP. XII.

Of the Propagation of Plants.

PLANTS may be propagated or multiplied several ways; as either by Seed, or by a Sprig cut, or pluck'd off from the Stock and set into the Ground; or by Grafting.

But before that the Seeds of Plants are committed to the Earth, the Soil must be duly prepared; that is, it must be turn'd up by the Plough, or dug with a Spade, or cut with a Weeding-Hook, or broke with a Pick-axe, and the Clods broke with a Harrow or Rake. All which pains is taken, partly to root out the Weeds and unprofitable Herbs; and partly to make the Ground more light and loose, that the Seeds or Slips may the more easily take root in it, and spread their fibres far and near, and by this means attract a more copious Aliment.

Nature directs us to the most proper Seed time, viz. when the Seeds have attained their full growth and maturity; or, when by the opening of their Husks they fall to the Ground; or by the contraction or shrinking of them are thrust out; or by the Down that grows about them, they are by the Wind scatter'd up and down through the Air.

The other way of propagating Plants, is by setting a Sprig or Slip, whether cut or pluck'd quite off, or whilst it sticks yet to its Mother, thrust down into and cover'd with the Earth, till it hath taken root. These Sprigs or Slips may be bigger or less, according to the Nature of the Plant. For some are set from a greater Branch, others from a Slip, others from a Twig, and others from a Shoot.

The Twigs, Sprigs or Slips that we would set, must be fresh and green: Yet VIRGIL tells us, that the dry Sprigs of an Olive, if set, will grow notwithstanding:

*An Olive Branch, tho' dry, will shoot,
If set in Earth, and spread its driving Root.*

R r r

I. Plants are propagated by Sowing, Setting, and Grafting.

II. The Soil is to be prepar'd for the Reception of Seed.

III. The fittest time for Sowing.

IV. Of Propagating Plants by Slips or Sprigs.

V. What kind of Twigs or Sprigs are to be set.

It is also observable, that the more tender any *Plants* are, the later must their *Sprigs* or *Slips* be set, that is, about the middle or latter end of the *Spring*, in these colder *Climats*: And if the *Weather* permits, they must be watered as soon as set; I say, if the *Weather* permits; for in cold *Weather*, too much *Moisture* is apt to spoil them. And so also, if it be a clear *Sky*, and the *Sun* shine hot upon these new set *Twigs* or *Slips*, they must be shaded, lest the heat of the *Sun-beams* should scorch and dry them up.

VI. In the Second place, *Plants* are propagated by *Grafting*: Now *Grafting*, being taken in the largest Sense, is such an application of a *Graft* or *Bud* to its own *Stock* or *Branch*, or to that of another *Tree*, whereby they become united and grow together. Now forasmuch as the most part of the *Sap*, ascends between the *Inner Bark* and the *Wood*, the whole Art of *Grafting* consists in this, that the *Inner Bark* and *Wood* of the *Stock* and *Graft* do answer exactly one to another; or that the *Scion* or *Bud* be so applied to the *Stock* or *Branch*, that the inner and outward *Bark* both of the *Stock* and *Scion* may so exactly answer, and make one continued *Body*, and one *Even Surface*, that the *Juice* may readily and freely flow from the *Stock*, to the *Graft* or *Bud*.

VII. The End of *Grafting*, is to meliorate the Nature of *Plants*, by changing them into others. For since there is a twofold *Concoction* of *Food*, the one in the *Stock*, and the other in the *Graft*; it cannot be otherwise, but that the *Alimental Juice*, by these different *Strainings*, must be the better prepared, and partake of new *Qualities*: And therefore we find, that *Plants* by *Grafting*, do not only bring forth larger, but also better *Fruit*, than the *Tree* doth from whence the *Graft* is taken: And it is found by Experience, that the *Tree* which grows from the fruit of a *Grafted-tree*, or the *Sprig* thereof set in the *Ground*, doth bring forth less and meaner *fruit*, than doth the *Graft* it self, from whence it was taken. Hence it is also, that we see one and the same *Tree* laden with diverse *Fruits*; yea, and the same *Fruit* having a different taste, smell and colour, in one part of it, from that it hath in the other, as also late *Ripe Fruits* to become early *Ripe*, and such as are *Green* to become *Red*.

VIII. There be three ways of *Grafting*: The first is within the *Inner Bark*, when the *Graft* is put in between the *Wood* and the *Bark*, and is ty'd fast with a *Thread* or small *Cord*. This way of *Grafting* is most proper for *Trees* that have a thick *Bark*, and abound with *Sap*: Because the *Bark* draws abundance of fat *moisture* out of the *Earth*; such as are the *Fig-tree*, *Cherry-tree* and *Olive-tree*. Wherefore, he that would graft after this manner, must have a little *wedge*, made of some very hard *Wood*, and drive it in between the *Bark* and the *Wood* gently, so as not to rend the *Bark*, and in that aperture must graft his *Scion*. This way of *Grafting* was by the *Ancients* called *Infoliation*, and is still in use with us, where the *Bark* is thick, and a small cleft to graft in cannot so well be made.

IX. The second way of *Grafting* is, by means of a *Cleft* made in the *Stock*, into which the *Scion* is put, so as that the *pith* of the one may be joyned with the *pith* of the other; and then the *slit* must

be stopp'd up with *Clay*, and bound up with the *Bark* and *Moss*. This way of *Grafting* is made use of in those *Trees* that have a thin *Bark*, and are of a drier *Complexion*, their *Moisture* living not much in the *Bark*, but within the *Pith*; such as are the *Citron-tree* and *Vine*. And this way is properly call'd *Grafting*, which must be quickly done, lest the *Scion* which is to be grafted, should by delay become over dry.

The third way of *Grafting* is done by *Inoculation*, wherein the *Bark* of the *Scion* that is to be *Inoculated*, is so joyned to that of the *Stock*, whence the like quantity of the *Bark* is taken, that the *Buds* and *Eyes* of the one, may exactly answer to the *Buds* and *Eyes* of the other. For there is a certain fat clammy *Moisture* between the *Rind* and the *Stock*, by which the *strings* of the *Scion* are glewed and joyned to the *strings* or *fibres* of the *Trunk* or *Stock*.

There be other ways of *Grafting*; as that which is done by *Emplastration* or *Plastering*, whereby some part of the *Bark* of a *Scion*, with its *Buds*, is put into the *slit* of the *Bark* of a *Stock*, and the *Bark* of the *Stock* so closed again upon it, as that no mark of the *slit* remains; and afterwards is plaister'd and bound up. Another way is by *Boring*, when the *Graft* is put into the *Hole* that is bor'd into the *Stock*. There is also another way, which the *French* call *En perche*, when many little *Sprigs* with their *Buds* are grafted into a perforated *Perch*. But all these, and other such like, are reducible to the 3 ways already mention'd: Forasmuch as all of them agree in this, that the *strings* of the *Sprig* or *Bud*, must agree and answer to the *strings* of the *Stock* whereinto they are grafted; and that by this mixture or coalescence, the wound may be cover'd or grow together, leaving the *Bark* somewhat rough in that place. They agree also in producing the same effect, that is, the melioration of *Plants*, by reason of their *Cocktion*, both in the *Stock* and in the *Graft*, where the *Alimental Juice* is further prepar'd and purified.

By this Art of *Grafting*, not only *Trees* of the same Nature are mingled, as it were, and united; as *Apple-trees* with *Apple-trees*, *Pear-trees* with *Pear-trees*, &c. but also any other *Trees*, tho' never so different in Nature. Yet they who would have their *Grafts* to thrive, had best set them on a *stock* of the same kind; because the *strings* of *Plants* that are of a like Nature, do better agree together, and have their *pores* and *passages* dispos'd in one and the same manner. However it is observ'd, that in process of time the *Seed* of the *Graft* doth very much degenerate: The Reason whereof is, because the *Seed* proceeds from the *Matrix* or *Pith* of the *Tree*, which being the product of the wild *Stock*, by degrees affects the *Seed*, and makes it to degenerate.

Some, it may be, will question how it comes to pass, that the *Scion* unites with the *Stock*, seeing that their *pores* do not answer to one another, but differ in their *situation* and *figure*. To which I Answer, That it is not necessary that all the *pores* of the *Stock* should agree with those of the *Graft*, or that every one of both their *strings* should be united; it being sufficient if the greatest part of them answer to each other, and give way to the passage of the *Alimental Juice*. As we see that 2 pieces of *Glass* laid upon one another, tho' all the

X. The third way of Grafting is called, inoculation.

XI. All other ways of Grafting are reducible to these three.

XII. The Nature of the Graft becomes changed in process of time.

XIII. What Pores of the Stock correspond or agree with the Pores of the Graft.

the pores do not exactly agree, do notwithstanding transmit the *Light*. For we must not imagine, that the *Graff* is joyned to the *Stock*, into which it is *grafted* with the same firmness and evenness, as its own connatural Parts are; since it hath often been found, that in an *Old tree*, the Part that hath been grafted on it, hath been torn off by a strong *Wind*, tho' for many years together, it had been united to it no otherwise, than as if it had been a Connatural part of it. For in order to the conveyance of the *Juice* from the *Root* to all the parts of the *Tree*, it is not necessary that all the *Pores* should exactly agree; because we find that the *Earth* affords Nourishment to *Plants*, notwithstanding that their *Pores* do not every way agree with those of the *Earth*. And tho' we should grant, that such a conformity of *Pores* should be necessary for the common Nourishment of the *Stock* and the *Graff*; yet I see no reason, but that the same conformation may be wrought in process of time, because the *Sap* that comes from the *Root* hath power of making to it self *Channels* and *Passages*, as hath been hinted before: For the *Fire*, by the *motion* whereof it is driven upwards, thrusting it forwards, helps it to make these *Passages* and *Channels* for it self.

XIV. To the end that *Grafting* may be duly performed, we must take heed, *First*, That the *Scion* to be *Grafted*, be not too soft or tender; for then, because of the tender texture of its *Firings*, it will not be able to bear the hardness of the *Stock* into which it is *Grafted*. Neither on the other hand must it be too dry; for in that case it will not unite and grow into one with the *Stock*. *Secondly*, That the *Graff* be taken from a fruitful and good *Tree*, and, as near as may be, of the same kind; as the *Graff* of an *Apple-tree*, upon the *Stock* of an *Apple-tree*. For if they be of different kinds, the *Fruit* thereby becomes spoiled; as if one should graft an *Apple-tree* upon a *Willow* or an *Ash*, the *Apples* will be found like to a *Crab* or *Wilding*. *Thirdly*, That the *Scion* be without any delay grafted, lest the *Air* entering into the *Pores*, should hinder their growing into one. *Fourthly*, That the *Stock* be duly slit, lest the *slit* being made too deep, should hinder the closing of it up again. *Fifthly*, That the *Graff* be so cut, as that the *Woody part* of it may joyn with the *Wood*, and the *Bark* of it with the *Bark* of the *Stock*. *Sixthly*, That the *Stock* on which we intend to graft, have stood in the ground for some Months, lest in case it should not be well rooted, it might not furnish *Sap* enough to feed its young Nurling. *Seventhly*, The top of the *Scion* is to be cut off, that by beating back the *Juice* it may swell and grow bigger. *Eighthly*, That when the *Graff* is put into the *slit*, the place must be pasted about with *Wax* and *Gum*, or with *Clay* and *Moss*, to keep out all external Moisture. *Ninthly*, That a fit *Season* of the Year be observed; which is, after the *Winter Solstice*, and after the Blowing of the *West Wind*; that is, from the 7th of *February* to the *Spring Solstice*. *Tenthly*, It is also to be noted, that some *Trees* are altogether unfit for *Grafting*; as the *Oak*, the *Fir-tree*, and other *Resiniferous-trees*; because the *Oak*, by reason of its hardness, will not be slit; and when slit will not grow together again: And *Resiniferous-trees*, because of their clammy *Liquor*, have their pores so obstructed, that the *Juice* cannot be readily

conveyed to the *Graff*. And, *Eleventhly*, That the parts of the *Scion* may retain the same situation when grafted on the *Stock*, as it had before it was cut off from its own *Tree*: As by Example, If the *Graff*, before it was cut off from the *Tree* did lean towards the South, in *Grafting* it must likewise be turned that way. See the *Natural History concerning Plants*.

CHAP. XIII.

Of the Colours of Plants.

AS to our present purpose, it is sufficient for us to know, that *Colours* are nothing else, but certain modifications of *Light*, caused in Bodies by the different disposition of their Surfaces. Whereof we have a manifest proof in cutting of an *Apple*, the inner parts whereof appear white at first; but soon after turn yellow, and lastly become of a brown Colour, according as its outward parts are more dried. Such a modification of *Light* does especially belong to *Plants*, since that all their parts are ting'd with some Colour or other, and are remarkable for their whiteness, yellow, red Colour, &c. yea, and sometimes are successively green, yellow, red or white, according as the Texture of the little particles, whereof they are compounded, is changed, and the disposition of the surface alter'd. The Matter therefore in question is, What that is in *Plants* that makes the *Light* reflected from them to acquire such and such Modifications, which impress these Sensations on the Eye.

The Roots of *Plants* are generally white; because they contain much *Spermatick matter*, which being compressed by the *Earth* that lies round it, and hindered from flying up into the *Air*, is forced to return into the substance of the *Plant*; where, by the warmth of the inner part of the *Earth*, it is concocted anew, and being coagulated into a kind of frothy Substance, doth reflect the *Light* on all sides, and so produce a white Colour. For the Reason why *Snow* and *Froth* are white, is, because they consist of little round Bodies, which from every point, reflect the *Sun-beams*. For the smaller these Bubbles are, the more white doth the Subject appear; for seeing that every one of them, from all their parts, reflect the *Light*, it must needs follow, that the more there are of these, within that determinate Space, the more Rays will be reflected; that being a white Colour, which comes nearest to the Nature of *Light*. Hence it is that *Liquor*, tho' it be of never so black a Colour, turns white as soon as it is turned to *Froth*; as appears in the froth of *Ink*; and therefore it is no wonder that the Root of a *Plant* being cover'd with *Earth*, appears white, because it consists of clammy Humours, which by the warmth of the *Earth* is easily turned into little round Pellets.

And it is for the same Reason that a *Lilly* is white; because the surface of it riseth into Bubbles, from all the several parts whereof it reflects the *Light*. For in a *Lilly*, the Alimental Juice is very exactly percolated, and its substance being well concocted, turns to round pellets or bubbles. In like manner as we see, that our food becomes turned into Chyle, when after digestion in the *Stomach*, it is resolved into little round Bodies; which

i. What Colour is.

ii. Why the Roots of Plants are commonly White.

iii. For the same Reason a Lilly is White.

Chyle

Chyle afterwards in the *Breasts* becomes turned into *Milk*. The Reason therefore of the *whiteness* of a *Lilly* is, because the little *Skin* wherewith its *Substance* is covered, consists of round *Pellers*, as is manifest to those that look upon it through a *Microscope*.

IV. Some *Flowers* are *Red* as *Roses*, and *Tulips*, because their parts are so disposed that the *Globuli* of the *Second Element*, which constitute *Light*, are by them more swiftly whirl'd about than they move to right lines. Wherefore whensoever the *light* in any *Body* is so modified, that its *Aethereal Globuli* are more swiftly turned round, than they move right forwards, than the surface of those *bodies* from whence the *Light* is reflected appears *Red*. Thus a *white Flame*, when *smoke* comes to it, turns *Red*. The *Sun* through a *Mist*, the *Planet Mars* by night, the *Moon* in the *Clouds*, a glowing *Coal*, and many other things are *Red*. Some *Fruits* therefore as *Cherries*, *Grapes*, *Mulberries*, &c. are of a *Red Colour*, because the *Juice* whereof they consist, having never been exactly strained, and therefore containing several *Particles* that are not sufficiently digested, makes those *Fruits* to appear of that colour, by reflecting the *Light* accordingly.

V. A *Yellow Colour* is peculiar to the *Leaves* of *Trees* and *Fruits*, whilst they are ripening; because having lost the moisture, which gave them their *Greenness*, they now contain nothing but such a *Juice*, as is well strain'd and prepar'd; which makes their outside to rise into greater *Bubbles* or round *Bodies*, which because they leave great intervals between them, must needs cause a great variation in the *Reflexion* of *Light*. For if you look upon *Yellow Bodies* with a *Microscope*, you will find them wholly rough and uneven, and full of innumerable protuberances; by which means the *Light* reflected from them becomes so modified, that the *whirling* about of the *Globuli* is somewhat more rapid than their *motion* to right lines. For the *Yellow Colour* mediates betwixt *White* and *Red*; which may be demonstrated to the *Eye* from the mingling of *Liquors*; for if you mix any *White* and *Red Liquor* together, the result will be *Yellow*. And the same will be if we twist a *Lace* or *Girdle* of the smallest *White* and *Red Threads*.

VI. *Blue* is the peculiar *Colour* of some *Flowers*, because the *Juice* that nourisheth them, is in such a manner concocted and percolated, that from thence such a degree of *Darkness* and *Transparency* results, as produceth such a *Reflexion* of the *Rays*, that the *Globuli* of them, have more of a straight, than of a circular *motion*. For a *Blue Colour* comes between a *Black* and *Red*; as appears in the *Air*, which in the day-time looks *Blue*, by reason of the *Bodies* that are tost up and down in it, and reflect the *Rays* to us. And forasmuch as these *Rays* are but few in number, and the *Shades* many, therefore it is necessary that the *Heaven* should appear of a middle colour between *Black* and *Red*, that is of a *Blue*, in the day-time. This will be made manifest to us by mixing a very fine *Red Powder*, with another that is *Black*, or by laying a black *Glass* upon a red *Glass*, and looking through them, for by either of these ways we shall find a *Blue Colour* produced.

VII. The most common colour belonging to *Plants* is the *Green*, which is observed in all of them as

well at their springing out of the ground, as in their growth. The cause of this *Colour* is the abundance of *moisture* that is in *Plants*, when it is but slightly strained and elaborated. Hence it is that those *Herbs* and *Leaves* have more of this *Greenness* by how much the more they abound with *moisture*, and less of it, as the *moisture* is less, and better digested. This *Green Colour* is mixed of *Yellow* and *Blue*; which may be made out by several experiments; for if we look upon the *Sky*, which is *Blue*, through a *Yellow Glass*, it will appear *Green*; so likewise if we lay a *Blue Glass* upon a *Yellow*, and look through it upon any *Object*, it will appear *Green*; and so we shall find that by mixing a *Blue* and *Yellow Colour'd Liquor* together, the mixture will be *Green*.

There be many *Flowers* that are of divers colours, as *Tulips*; which cannot proceed from any other cause, but the different concoction of the *Alimental Juice*; because the matter is better preserved and purified in the great *Bulbous Roots* of *Tulips*; and better strained through their long and thick *Stalks*, wherein also it is the better concocted and distributed. But yet it cannot be expected that *Tulips* every year should retain the same colours; for the temper of the weather changing considerably every year, it cannot be otherwise but that thereupon a different concoction, preparation and distribution of the *Alimental Juice* must follow, and consequently the colour also be changed. Yea, we find sometimes that *Tulips*, in one and the same year do change their colours, and that such as before were *White*, turn *Red*, and the *Red*, *White*. When streaks of a *Purple Colour* appear in a *white Tulip*, it is a sign that the thicker parts of the *Juice* do cause an obstruction, whereby the free motion thereof to the utmost parts of the *Flower* is hindered.

And the same may be said of the *Leaves* and *Fruits* of *Trees* changing their colours. For the *Leaves* are *Green* at first, by reason of the plenty of *Moisture*, and the *Juice* that is not thoroughly elaborated or prepared; and from this *Green Colour* they are changed into a *Reddish*, and lastly from that to a *Yellow*; because the *Moisture*, which at first was the cause of the *Green Colour*, being diminished gives way for the *Red Colour* to succeed, and afterwards flying all away, they are thereby changed into a *Yellow Colour*, till at last extremeness turns them *White*. In like manner *Fruit*, as it comes to be ripe, quits its *Green Colour*; which becomes changed into some other; because the *Juice*, which before was raw, as wanting due preparation, when the *Fruit* grows ripe, becomes depurated and percolated to perfection: so that the contexture of parts being by this means changed, it is no wonder that the *Fruit* loseth its *green Colour*, and becomes *Red*, or *Yellow*, or of a *Colour* mixt of both.

CHAP. XIV.

Of the several Tasts of Plants.

BY the word *Tast* or *Savor*, we understand that *virtue* in *Bodies*, whereby they are able to produce in us the sense of *Tast*. Which virtue consists in the *Particles* of *Bodies*, inasmuch as they are sufficiently diluted, subtil and agitated

ral Colour of Plants is the Green Colour.

VIII.

What is the Cause of that variety of Colours that is in Tulips.

VIX.

What is the Cause of the Yellow Colour that appears in the Leaves of Plants.

IX.

Why Leaves and Flowers change their Colours.

I. What Tast or Savor is, and wherein it consists.

to enter the pores of our *Tongue*, and to move those *Nerves*, wherewith the *Instrument of Tasting* is furnish'd. For tho' *Taste* be properly in the *Mouth*, and that the *Tongue* or *Palat* is formally that which *tastes*; yet it may be said, that the things themselves, which are taken into our *Mouths*, are the Causes of the said *Taste*, and according to their several *magnitude*, *figure* and *motion*, do produce different *tastes* or *savours*. So that things *savoury*, or endued with *taste*, are said to be such, only because they move the *Filaments of the Nerves* of our *Tongue* in such a manner, as is necessary to produce in them the *sense of Tasting*. And forasmuch as *sensible Objects* cannot affect those *Nerves*, except they be endued with a certain *motion*, *figure*, and *magnitude*; therefore to these three we must assign all the diversity of *Tastes* or *Savours* we meet with in any *Objects*.

II. This is evident from the *Inspidness* we sometimes find in *Plants*, and their several parts. For if we enquire into the Reason why some of them are *Inspid*, and do not affect the *Tongue* or *Palat*, we shall find the Reason to be, because they do not furnish such *Particles*, as by the assistance of *Moisture* can enter the *Tongue*, and strike its *Nerves*. Thus we find, that when *Grapes* are first knotted, they impress no affection upon the *Tongue*, and do only touch the outside of it, without entering its pores; because the *particles of Juice*, which come up from the *Root* to compose them, do stick close together, and are not easily separated. Daily Experience also teacheth us, that *Water* is in a manner wholly inspid, because its *Particles* are so thin and subtil, that they can affect the *Organ of Taste* very little or nothing. In like manner *Air* is void of all *Taste*, because it floats only upon the *Spittle*, and the Parts of it, by reason of their extream lightness and subtilty, can make no impression upon the *Tongue*.

III. That a thing be *savoury*, it is necessary for its Parts to be separated from each other, that so joyning themselves to the *Spittle* in our *Mouths*, they may variously affect the *Nerves* of our *Tongue*. Now this is done by means of *Heat*, the Property whereof is, to resolve *Bodies*, open their pores, and to make a ready way for the *Moisture* to enter. Whence it is, that when *Fruits* tend to Maturity, by means of the *heat of the Sun*, reconciling their *driness* and *moisture* together, various *Tastes* are impress'd upon them, according to their different degrees of Maturity: First, an *Astringent taste*, then a *Harsh taste*, afterwards a *Sour*, and last of all, a *Sweet taste*; and if the *Heat* be too great a *smart* or *biting*, and *bitter Taste*.

IV. An *Astringent taste* we find in all unripe *Fruit*, and more especially in *Sloes*, which with great harshness and astringence affect the *Tongue*, as if they prick'd it with *Pins* and *Thorns*; because they consist of *keen* and *stiff Parts*. For the *Juice* whereof they consist being not well strained, contains many *stiff* and *inflexible little Bodies*, such as are the *particles* that compose *Salt*; so that it is no wonder that they exasperate the *Tongue*, and astringe or contract the same.

V. In *Onions*, *Ginger*, *Pepper*, *Mustard-seed*, &c. we perceive a *smart* and *biting Taste*; because the *particles* of these *Objects* do prick the *Tongue*, and cause the same Division in it, which *Fire*

would, if applied to it. The Reason is, because they consist of long, thin, and stiff *particles*, which make the *Bodies* whereto they belong dry and stiff. But being boil'd in *Water*, they lose their *Acrimony*; for that the *Moisture* penetrating them, dissolves their *Salt* and other smart little *Bodies*, and opening their pores, carries them away. Yea, some of these may be so macerated or soaked, as that by quitting all their *Biting* and *Harsh particles*, they may become *sweet*, and at last *insipid*.

VI. We meet with a *Sweet taste*, almost in all *Ripe Fruits*, which with great smoothness and evenness affect the *Tongue*. For in *Ripe Fruits*, by the continual beat of the *Sun*, the *Alimental Juice* is very exactly and thoroughly strained, and the *particles* that before were entangled, are resolved, by which means they readily enter the pores of the *Tongue*, and affect it with a pleasing *Titillation*. This *Taste* is most pleasant and grateful to young *Children*, the small strings of whose *Nerves* are more fine, small and subtil; but is not so acceptable to those who have a thicker *Texture of Nerves*, being affected by what is *acrimonious*, and therefore look upon a *sweet Taste*, to be unpleasant.

VII. A *Sour taste* is found in *Lemons*, *Sorrel*, and the like, which do prick and cut the *Tongue*. It is felt somewhat in the same manner, as a *smart* or *biting Taste*, saving only that *Sour things* are accompanied with a *sense of constringent Cold*. The Reason is, because this *Savour* consists in subtil and sharp *Particles*, which do easily penetrate the *Organ of Taste*, and pierce it like so many *Thorns*. And therefore we must conclude, that these *Bodies* consist of longish and stiff *particles*, somewhat like *Needles*: Which we shall readily admit, if we consider that all *Fruits*, before that they come to their full *Ripeness*, are of a *Sour taste*, which could not be, if that *Taste* did not include something that is common to them all. Now we can meet with nothing that is common to them all, except that *Disposition of Parts*, seeing they consist of an *Earthy Juice*, which did cleave to the long and thin pores of the small *Twigs*, whence these *Fruits* do grow.

VIII. A *Bitter Taste* is perceived in some rotten *Pears* and *Apples*, &c. in the eating whereof the strings of the *Nerves* are unduly affected, and unpleasantly vellicated. For *Pears* and *Apples*, when they begin to putrefie, get rough, uneven, and prickly *particles*; because then the more subtil and refined *particles* fly away, leaving none but the grosser and thicker behind them. For *Putrefaction* is such a *Resolution of Parts*, by which things become worse than they were before. Hence it is that they who drink *Wine*, immediately after they have eaten a tainted *Apple*, and tending to *putrefaction*, do perceive a *Bitter taste*; because the *Wine* mingling it self with those putrid *particles*, conveys them to the inmost pores of the *Tongue*. This *Bitterness* is sometimes occasion'd by too great *Heat*, when it is continual, and acts for a long time together upon *Fruit*. So that if *Fruits*, after their full Maturity, should continue long upon the *Trees*, it is not to be question'd, but that by being too long expos'd to the *Heat of the Sun*, their *particles* would become so rugged and twisted, that none would be left in them, to affect the *Tongue* with a *Sweet taste*, but would all ex-

asperate and bite it. A confirmation whereof we have in *Flesh*, which by too great heat of the *Fire* becomes scorched and burnt; and by this means acquires a *Bitter taste*, as doth also the *Crust of Bread* that is burnt, by being baked in an over-heated *Oven*.

IX. *Mixt Tastes are found in some Fruits and Plants.* Neither are these simple *Savours* or *Tastes* only found in *Plants* and *Fruits*; but also compound *Savours*; as the *sweet* and *sour Taste* which is commonly found in *Fruits*, that are not yet arrived to the utmost degree of *Maturity*: As when some

IV. of their parts are longish and stiff, which prick the *Tongue*; whereas others, more smooth and pleasant, softly flowing over the *Nerves* of the *Tongue*, do only produce a kind of pleasant *Titillation* on the *Tongue*. Another *Taste* is that which is *Harsh* and *Sour*, which is that we perceive in those we call *rough Wines*. Another, *Sour* and *Astringent*, which *taste* is found in the *Juice* of *unripe Grapes*, called *Verjuice*; the Cause whereof is this, that the particles which constitute the *Grapes*, are by the Heat of the *Air* separated from each other, and so acting independently, they produce both a *sour* and *astringent Taste*.

CHAP. XV.

Of the Odour or Scent of Plants.

I. *Wherein Taste and Scent do agree,* **O**odours, or *Scents*, have some affinity with *Tastes*, as being much deriv'd from the same Principles. For as *Taste* consists in those little *Bodies* which penetrate the *Tongue* and *Palat*, and diversly affect them, according to their various *Magnitude*, *Figure* and *Motion*; so *Odour* consists in those particles which, flying in the *Air*, do enter our *Nostrils*, and variously affect the same. There is also another *Resemblance* between them, in that they are in a manner denominated alike, and are distinguish'd by the same Differences. For as *Tastes* or *Savours* are chiefly distinguish'd into *Astringent*, *Smart* or *Biting*, and *Sweet*: So of *Odours* or *Scents*, some are *sweet*; as in *Musk*, *Roses*, *Orris*, &c. Others *smart* and *stinging*; as in *Brimstone*: Others, *stinking* or *nasty*; as in *Bugs*, and some *Excrements*: Others, *sharp*, as the *Scent* of *Spike*, &c.

II. *How Savours and Odours differ.* But yet *Scents* and *Tastes* differ in this, that they do not consist in the same parts, nor affect the *Organs* after one and the same manner. For the particles that are productive of the sense of *Taste*, are moist; whereas those that cause *Odours*, are very dry and subtil. They differ also, in that a *savoury Object* cannot move the sense, except it touch the *Organ*; whereas a *scented Object* strikes the *Organ* at a distance: So that the *Tongue*, by its *Moisture*, takes out the *Taste* from the *Object*; whereas the *Nostrils* only admit the *Odour* transmitted to them from the *Object*.

III. *The Nature of Odours consists in the efflux of Particles.* Whence we may conclude, that the Nature of *Odours* consists in the *Efflux* of certain particles; which being diffus'd in the *Air*, enter the inmost parts of the *Nostrils*, and there affect some *Nerves* derived from the *Brain*. This we perceive in *Frankincense* cast upon *Coals*, and any other *Perfume*, which evaporates in the *Air*, and is dispers'd into innumerable particles. Whence it is that *Hard Bodies*, which in their compact Nature afford

no *scent*, when put to the *fire* yield an *Odour*; because, by the forceable motion thereof, some of those particles are set at liberty, and diffus'd through the *Air*. 'Tis for this Reason, that *Spanish Wax*, which we make use of to seal *Letters*, doth yield a *sweet Scent*, when put to the *fire*; as also that one *Stone* rubbed against another; and *Iron* violently struck by another *Iron* do send forth a *smell*, which before this motion was not perceptible. From which Instances it may appear also, that the *Odours* of *Flowers* consists in an *Exhalation* or *Evaporation* of some of the parts of them, which is the more evident, because when that is gone, they remain void of all *smell*.

IV. *Why some Bodies have no Scent at all.* Neither must we conclude from hence, that all manner of *Effluvia* that proceed from *Bodies*, must impress the sensation of *Odour*; for besides the emanation of particles, it is required that they move the *Organ*, and that in such a manner as is fit to produce this sense. For the particles of some *Bodies* may be so very fine and small, that they cannot sufficiently move the *Organ*: Thus we find, that neither the *Air* we draw in, nor the *Vapours* that arise from the *Water*, do excite any sense of *Smelling* in us. And on the contrary, some *Effluvia* are so gross, that they cannot reach the *Organ* of *Smelling*; or if they do, are more apt to spoil it, than to produce any sense of *Smelling* in it.

V. *The difference of Odours depends on the variety of Parts that flow from a Body.* The Diversity of *Odours*, for the most part, depends on the same Principle, whence the variety of *Savours* doth proceed; that is, from that difference there is in the *magnitude*, *motion* and *figure*, of those particles that breath out from *Odorous Bodies*. Which we shall more readily assent to, if we consider that there is some Analogy or Resemblance between *savoury* and *odorous Objects*; and that those which agree in *taste*, do generally agree in *smell* also. Thus all *smart* and *biting Things* to the *taste*, are also observ'd to have a *sharp* and *stinging Smell*; and *bitter Things*, to have a *scent* that partakes something of *Bitterness*. The Reason whereof is, because the same Particles, which being mingled with *Moisture*, produce *Taste* or *Savour*, when exhal'd into the *Air*, and entering our *Nostrils* create the sense of *Smelling*. In like manner *Bodies* that are insipid, are commonly also destitute of *scent*. Thus *Unripe Fruits*, which have no more than an imperfect *Taste* (and the same may be said of *Flowers*) yield little or no *Odour*. I said, that it is so for the most part; because it sometimes happens, that there is not this agreement between the *Taste* and *Scent* in *Objects*; as appears in *Roses* and *Myrrh*, which tho' they yield a pleasant *smell* to the *Nostrils*, yet have a *bitter* and *unpleasant Taste*.

VI. *Why Odours are more perceived in Hot Seasons and Climates.* Nothing more conduceth to the production of *Odours*, than *Heat*; because it readily opens and resolves *Bodies*. For as we see that *Smoke* is excited by *Fire*, and that the more subtil parts of the *Wood* are carried up into the *Air*: In like manner *Heat* divides the parts of *Bodies*, dissolves their *Texture*, and makes way for them to fly abroad. For we observe that *fruits* and *flowers* smell by so much the more, as their *Juice* is better prepared by *Heat*, and more thoroughly digested. A *Lilly*, the more it hath been concocted with a *lasting heat*, the more *odorons* it is. *Sweet Woods* and *Spices*,

Spices, the hotter the Countries are they grow in, the more strongly Sweet-scented they are; as appears in *Frankincense*, *Storax*, *Myrrh*, *Balm of Gilead*, &c. Because the Juice of Plants in those Countries being exceeding well digested, is the more easily resolv'd into an *Odoriferous breath* or *steam*. Wherefore it is not to be wondred at, that the Plants that grow with us are not so odorous, as those that grow in *Arabia*, and other hot and dry Countries; because the Concoction cannot be perfected for want of *Heat*, the superfluous moisture hindring the more dry particles from exhaling into the Air. Hence it is that most things, when dried, do acquire a stronger Odour; and for the same Reason, *Ripe Fruits* are more and better scented, than those which are unripe. This proves all *Odorous things* to be hot, and that they suffer a continual efflux of their parts. And therefore those who would preserve the Sweet-scentedness of *Musk*, do wrap it in *Cotton*, which doth entangle its *Effluvia*, and hinder it from exhaling too fast. Accordingly also we find, that in *Colder weather* scents are dull and weak, because *Cold* stops the Pores of Bodies, and by keeping their parts at rest, hinder them from breathing out in Exhalations.

VII. Flowers are observ'd not to smell so sweet near at hand, as at a distance, if it be not too great. The Reason is, because they who put the flowers to their *Nostrils*, do take in many *Heterogeneous parts* of *Herbs*, which are mingled or entangled with those of the flower; but are not able to accompany them at any distance, but are soon scatter'd in the Air, or fall down, because of their Thickness. Hence it is that a small quantity of *Civet* smells sweet, whereas a greater quantity of it rather stinks, and offends the smell. To which we may add, that the *Odorous Exhalations* scatter'd in the Air, become there strained and defecated of their more gross and impure parts; as we see that *Water* mingled with *Wine*, doth dull and weaken the smell, as well as the strength of it; and therefore it is no wonder, that an *Odorous Exhalation*, that hath been diffused through the Air, is more grateful, than that which we draw from the Body it self, apply'd to our *Nostrils*.

VIII. Forasmuch as Bodies continually send forth some of their Particles, we must conclude they cannot but waste by degrees. So we find, that those Sweet-scents that are excited by Heat, do waste by degrees, and at last lose all their Odour. But those Perfumes which do not stand in need of this Excitation by fire, as *Musk* and *Civet*, do not so soon consume, but continue their scent for a long time, without any sensible diminution; because the agitation of their particles is very moderate, and consequently but a few of them are disperfed or lost in the Air.

CHAP. XVI.

Of the Diseases and Death of Plants.

I. Forasmuch as Contraries discover each others Nature, and that Life and Death are Contraries, it will not be difficult to find out why Plants do perish; and what the Cause is, why they cease to be nourished, to grow and increase; and to express it in one word, why they die. For

seeing that the *Alimentary Juice* is the immediate Principle of Motion in Plants, and that their Life doth consist in the due distribution thereof by Heat; it evidently follows, that the death or perishing of Plants must consist in the defect of this *Alimentary distribution*.

But because this Defect may proceed from many Causes, we will first speak of the Distempers to which they are subject, and shew how many several ways their *Vital functions* may be perverted. For besides the undue disposition of their Parts, as when the Top of them is too much bended down towards the Earth; when they are full of knots, and when the distribution of their Aliment is interrupted by callous Bumps; when their parts are separated; or when they exceed, or are defective: I say, besides these, there are many other ways whereby they may be brought to their end; as by an undue Temperature, when they are either choaked with too much Moisture, or consumed by too much Heat; when they are shut up and grow stiff, by extream Cold; or wither and pine away, by too much Drought. The Ancients reckon up those Distempers of Plants, which are described as followeth.

The Disease called *Rubigo*, or *Mildew*, in Pulse and Corn, is caused by a Dewy Moisture, which falling upon them, and continuing there, for want of sufficient Heat of the Sun to draw it up, doth by its biting sharpness, or Acrimony, scorch and corrupt the inmost substance of the Seed. This Disease also seizeth Vines, but may easily be prevented by cutting them later in the year; for the late pruning of them, makes them to flower so much the later, which generally prevents this Evil, because it seldom happens towards the latter end of the Spring. Moist and Dewy places are most subject to this Damage; as Vallies and shut up places, where the Winds have not their free Course; High ground being not subject to it.

Roration; which is a distemper of kin to that of Mildew, is, when by too much Rain or Dew, Vines are blasted in their flowering, and bring forth only small and dwindling Grapes. And after the same manner other Plants are also spoiled, whilst they are yet young and tender, and not sufficiently rooted.

Uredo, happens either when the Sun with too great heat scorseth the Leaves and Clusters of Grapes, before that the Rainy or Dewy Moisture is shak'd off from them; or when Rain or Snow, lying upon the Tendrils or Buds of the Vine, is by Cold congealed to Ice.

Carbunculation, is the blasting of the new sprouted Buds of the Vine, in the Spring time; because then the Vines are in danger to be smitten, either by the excessive Heat or Cold. For by too much Heat, the Texture of the strings or fibres of the Vine become so dissolved, as that thereby the Native disposition of the pores becomes wholly changed; and again by Cold it is so compressed, that the pores thereby are shut up, and leave no passage for the *Alimentary Juice*.

Vermiculation is nothing else, but the Infestation of Plants by Worms; which Evil is very incident to Apple-trees, Pear-trees, and Fig-trees. For as Men, and other Animals, are subject to breed Worms, so Plants are obnoxious to the same distemper,

VII. Vermiculation.

per, especially such as bear sweet Fruits, for such as bear bitter or sharp Fruits (excepting only the Olive-tree) are never troubled therewith. The manner of these Insects infesting Plants is declared to us by MALPIGHIUS; It is yet more wonderful, saith he, that commonly, by means of one or two Eggs of a Flie left upon the Leaf of a Vine, Oak, or other like, the whole Leaf becomes drawn together like a Purse about the said Egg, and so withers; yea such is the strange force of one of these Eggs, that not only the Leaf on which it is laid, suffers thus, but the infection being communicated to the Stalk of the Leaf, and from thence to the sprig that sticks to it, and the Leaves that are on it, the whole Branch is twisted and writhed together, and so withers and dies.

VIII. *Defluvium*, is a distemper whereby Trees, in the Spring-time especially, lose their Barks, by reason of some sharp humour, that dissolves the Glew whereby the Bark was fastned to the Wood, whereupon they wither and die, being deprived of their Barks; except this Decortication be not round, but long-wise only, for then it is no prejudice to the Plants, unless it be very great indeed, especially in Resiniferous-trees whilst they are budding. This Distemper also proceeds sometimes from too much Drought, which young and tender Trees not being able to bear, they do easily shed their Leaves and Fruit.

IX. A deep wound made in any Tree kills it, except the Firr, Pine and the Turpentine-tree, which delight in being wounded, and by this means become fruitful, whereas they were Barren before: for they abounding with a Fat and Clammy Humour, do void part of it by the wound, and thus being unloaden of some of their superabundant moisture, are afterwards better nourished, and advance more in growth.

X. Plants, as Animals, perish two several ways, viz. by a Natural or Violent Death. Plants die naturally when Aliment is no longer transmitted to them from the Root; or when the Heat, that drives it upwards, and distributes it into all parts, vanisheth. For Heat, as is before mentioned, is the Principle of all motion in Plants, and therefore when that ceaseth, all the Functions of Germination and Nutrition must needs cease with it.

XI. Plants, may divers ways die violently; as first by a wound received; whereby we are not only to understand Cutting, Slitting, Pulling off the Bark, Boring or Lopping off the Top, but also Bruising, half Breaking, Tearing, &c. For tho' a Plant, whilst it is pluckt up out of the Ground, doth not suffer any wound, yet because the Passages whereby it drew in its Aliment, are stopt up, the parts that are towards the top must needs wither, and those that are near the Root must be choaked with the too great abundance of it.

XII. Plants also perish by too much Heat, when the Earth is parched by the Heat of the Sun, and all the Moisture or Juice dried up. Whence it is that young and tender Plants, do much sooner perish than those that are grown; for by reason of their tenderness the Heat more easily penetrates their Pores and opens them, and so makes way for the Juice to get out. Moreover their Roots being not so deeply fixed in the ground, when their moisture is exhausted, they cannot so readily draw in

more, to restore the Alimantal Juice, they have lost.

In like manner Plants perish by great Cold, which is very destructive to them when it is excessive, and especially when it comes after great Rain; for since the particles of Water, that insinuate themselves into the Bladders of Plants, do very much distend them, they can no longer contain themselves within their Bounds, but breaking out beyond them, do spoil the connexion of their parts, whence follows their total destruction. Accordingly we find that Plants by great Cold are parched and scorched, much in the same manner as if they had endured the most scorching Heats of Summer. We might now proceed to the answering of some Queries, as why Trees that are pluckt up by the Roots, and Branches that are lopt off from the Tree, do continue to live for some time, and do not die presently; why Wild Trees are longer liv'd than those that grow in Gardens and Orchards; but having fully spoken to these in the IX. Chapter of my Natural History concerning Plants, I thither refer my Reader.

CHAP. XVII.

Of Animals, or Living Sensitive Creatures.

AS Nature proceeds from simple things, to those that are more compound, and from meaner and viler things to those that are more noble; in like manner having now treated of Plants, that are a meaner kind of Living Creatures, I proceed to Animals, who besides the Life which they have common with Plants, are partakers of a kind of Sense and Motion. For so Animals are usually defined Living Bodies, furnished with variety of Organs, and endued with Sense and Motion. I say, Living Bodies, because they consist of such a contexture of sensible and insensible parts, that they cannot only recover the parts they have lost, but being excited by objects, can agitate themselves by various motions. So that the matter of an Animal are its Parts, or those Bodily Substances, that complete its Body, and are designed for the due performing of several Actions. And the due and becoming Union of these Parts, whereby an Animal, both in respect of his sensible and insensible Parts, viz. Fibres, Nerves, Passages or Conduits Valvules, &c. is so disposed, as to be able duly to exert his several actions, is his Form. What their Sense is, shall be declared anon.

The Life of Animals consists in a due disposition of Parts, and intense Heat, whereby the Alimantal Juice is digested, attenuated, changed and agitated. For the Parts of Animals are not so disposed, that the Alimantal Humour which is conveyed through them from the lower part, is from thence by an uniform tenor diffused every where, without any sensible heat, as in Plants: for in Animals there is a Part, which contains an enclosed Fire, to which the Alimantal Juice being conveyed by the Veins, doth there undergo an effervescence, and then from thence is driven through the Arteries, to moisten and quicken the whole Body; till after having circulated through the whole Body, it return again through the veins out of the Arteries to the same living Fire, there to be heated and recruited a-fresh.

What kind
of Fire is
that is
lodged in
the Head
of Animals
and how it
is con-

III. This Receptacle of *Fire*, in perfect *Animals* is the *Heart*, which is the most hot of all the rest of their *Parts*. Which *Heat* residing in the *Heart*, is called *Natural*, because it doth not presently vanish like to that *heat*, which is found in *inanimate* or *lifeless things*; but is preserved in the coldest *Season*, and as long as the *Life* of *Animals* doth continue. And accordingly it is said to be the first part that *lives*, and the last that *dies* in *Animals*.

IV. Altho' this *Native Heat* do continue till the Death of the *Living Sensitive Creature*, yet it is not always in the same state, for as it encreaseth all the while *Animals* grow up to their perfection, so after that the same is attained, it decreaseth again and grows weaker, till it be wholly extinguish'd. At the beginning of *Life*, when the more solid parts of the *Body* are yet soft and tender, they do not so much resist the motion of the *Fluid parts*, as when they are come to their full growth, and so because the *fluid parts* are less forcibly moved, the heat excited by them is so much the weaker also. But in *Old Age*, when the more solid parts of the *Body*, and those more especially through which the *Alimentary Juice* or *Chyle* is strained, in order to the making of *Blood*, begin by degrees to grow harder, and have their pores less crooked and winding, the *native heat* must need thereby be changed and grow weaker.

V. The Faculty therefore of *Sense* and *Motion* (which by some is called the *Sensitive Soul*) in *Animals* consists in a due disposition of the *Parts*, viz. their *Nerves*, *Muscles*, *Spirits*, *Fibres*, *Joints* and of their other *Organs*; by the help whereof *Animals* become differently affected from outward and inward objects, and are carried from one place to another. For all *Animals* (*Man* only excepted) are a kind of *Watches* or *Clocks*, which by a fit adaptation of their parts, have a *Bodily Principle* of *Motion* in themselves, as long as they are well disposed, and have whatsoever is required to perform and exert the several actions to which they are design'd. For all the Effects we perceive in *Animals* (*Man* excepted) have no other cause or Principle but the *Body*, neither is their *Sensitive Soul* any thing, but the constitution and affection of their *Bodily Organs*, and the *Spirits* or the purest parts of the *Blood*, fitted to the *Animal Life*, and the exercise of the *Senses*.

VI. And forasmuch as *Heat* is the Principle of all *Motions* in *Animals*, and that whatsoever belongs to *Life* or *Sense* is to be attributed to its continual motion; we must enquire, what this *Fire* in the *Heart* is, and what its Effects are. This *Natural Fire* then, which *Physicians* generally ascribe to the *Blood*, is hot, but without *Light*, and not much unlike to that, which ariseth from the mixture of two *Liquors*, viz. *Oyl of Tartar*, and *Oyl of Vitriol*. The Reason is, because after that the greatest part of the *Blood*, which hath been rarefied in the *Ventricles* of the *Heart*, is convey'd thence, through the *Arterial Vein* and the *Aorta*, that *Blood* which still remains in the same *Ventricles*, and that which is a-new convey'd into them, from the *Ear-Lappets* of the *Heart*, have the same respect to one another, as the foresaid *Liquors*; the one being instead of a *Ferment* or *Leaven* to the other, to dilate and warm it.

The Cause of the Perpetuity of this *heat* in the *Heart* is, partly because it is closely shut up and pent in there; and partly because this *Fire* is nourished and fed in the *Heart* by the *Blood* of the *Veins*, generated of the *Alimental Juices*, heated by a kind of *Fermentation*, and running into the *Heart*: yet so, as that at the same time this *Fire* doth also in its turn impart a heat to the *Blood*, and thereby preserve the Fluidity and motion of it.

The first effect therefore of this *Fire* is the Dilatation of the *Blood*, contain'd in the ventricles of the *Heart*, together with the warming and attenuating thereof. For it is common to all *Liquors*, that when they are distilled drop by drop into a very hot *Vessel* they presently swell and are dilated. Now the *Blood* being thus rarefied, wants a greater space, and therefore breaks forth from the *Heart*, much in the same manner, as the water resolved into *Vapours*, bursts forth from an *Æolipyle*; and the *Blood* that comes to supply the place of the former, rarefies in like manner as the former, and is extended to a far greater space.

From this successive Ingress and Egress of the *Blood* into and from the *Heart*, not only the *Heart*, but all the *Arteries* together, swell and are depressed; whence follows the *Pulse* of the *Heart* and *Arteries*, which is as often repeated, as any new *Blood* enters into the *Heart*, and the *Arteries* are extended. For as soon as any part of the *Blood* enters into the hot *Heart*, it presently swells and becomes dilated, by which means it puffs up and distends the *Heart*, and endeavours to get out. Which since it cannot obtain through the same ways by which it entered into the *Heart*, because of the different situation of the *Valves* or *Flood-gates* of the *Heart*, it forceth open the other *Valves* that favours its escape, and so gets out.

And this is the true cause of the *Bloods Motion* throughout the whole *Body*; for seeing that the *Arteries* and *Veins* that are fill'd with it, are continuous, and do not in the least hinder it from continuing its *Motion*, it cannot be otherwise, but that it must alternately, or by turns, with force break forth from the *Heart*, and from thence be driven into the *Arteries* and *Veins*. And it is by this means that the *Blood* derives the *Heat* it hath acquir'd in the *Heart*, to all the other parts of the *Body*. For the more frequent this motion of the *Heart* and *Arteries* is, the more *Heat* we find in our selves, and in so much the less time the *Blood* is carried to the utmost parts of the *Body*.

By this constant Circulation of the *Blood* all the Parts of the *Body* are nourished; because the thinner and purer parts thereof, being separated from the *Excrements*, are added to the parts, taking up the place of some particles which they drive away thence, or also grow and encrease, when greater or more particles of *Blood* come to restore the parts, than can be received into their narrow Pores. And therefore we find, that whilst a *Body* suffers a continual loss of *Blood* it is not nourished, but wastes away, and consumes.

By this perpetual Circulation of the *Blood*, the *Animal Spirits* are also generated, which are the most subtil and swiftly moved particles of the *Blood*, which like a most subtil *Wind*, or rather like a most pure *Flame*, do continually mount up to the *Brain*, fill its Cavities, and from thence through the *Nerves*, penetrate into the *Muscles*, and

VII. How this heat in the Heart comes to be perpetual.

VIII. The first effect of the Fire in the Heart, is the Dilatation of the Blood.

IX. Whence the Pulse of the Heart and Arteries doth proceed.

X. The Blood is carried throughout the whole Body of the Animal.

XI. The continual motion of the Blood is the Cause of the Animals growth.

XII. By the same motion the Animal Spirits are generated.

C H A P. XVIII.

What the Souls of Brute Beasts are.

A Brute Beast is by the Peripateticks commonly defined to be an Irrational Animal, or an Animal endued with Sense. Yea, they make them almost Rational, as supposing that some plain Foot-steps of Reason are observable in Beasts. But we on the contrary are persuaded, that a Beast is a meer Automaton or Engin; that is, an Animal destitute of all Knowledge, and consequently may be thus defined: A Beast is an Artificial Engin or Machin of GOD, furnish'd with a various and wonderful structure of Organs, containing in it self a material Principle of Life, Motion and Sense. For herein Beasts do differ from Men, that these have an Immaterial or Intellectual Substance joyned to Matter; which the former have not.

It cannot be deny'd, that there are some Actions in Brutes, which have a great resemblance with those that are in Men; whence some have concluded, that they had the use of Reason, tho' in an inferiour degree, in comparison of Men. How comes it to pass, say they, that when a Dog in hunting comes to a place where 3 Ways meet, having laid his Nose to 2 of them, he immediately casts himself along the third? How can it be conceiv'd, that Birds should be able to build their Nests, with such extraordinary Artifice and convenience for themselves and their young, if they be wholly destitute of Discourse and Reason? These and other Actions of Animals, have rack'd the Brains of several, and forced them to allow some foot-steps of Reason to brute Beasts. But this Question will be easily determin'd, by supposing 2 things.

First, That no brute Animals, how perfect soever they be, can express their Thoughts (if they have any) by Words: Which yet all Men, how dull and stupid soever they be, can do; neither are any of them so far distracted, but that they can discover their Affections by Words. The Reason of which difference doth not proceed from the Organs, seeing that several Animals, such as Parrots and Jackdaws, utter Articulate words, and yet for all that can never attain to our way of Speaking, that is, they can never manifest to others, that they understand what they pronounce. Whereas on the contrary, persons that are born Deaf, and to whom Nature hath deny'd the use of Speaking, can by signs discover their Conceptions to others, and make known what they desire or refuse, by their Gesture, Eyes, and the like. Now the want of this in Brutes, doth not only argue a less degree of Reason in them, but also strongly prove them to have none at all.

In the Second place, we must suppose that the Signs which have been invented by Men to represent their Conceptions, do differ very much from those Natural Voices and Signs, which are genuine Expressions of Bodily Affections. Wherefore seeing the former are not to be found in Beasts, and that they are not able any way to express their Minds; neither must we allow them to have any use of Reason.

If any one will say, That Beasts do discourse and talk together; this they must prove before we can believe them: For seeing they have Organs

and impart motion to all the Members. For we need not to seek for any other Cause, that makes those parts of the Blood, of which the Spirits are generated, to mount up towards the Brain, rather than to betake themselves elsewhere; but this, because all the Blood that proceeds from the Heart, doth by a Right line tend that way. And forasmuch as in the Brain there is not room enough to contain them all, and the passages they are to go through are very narrow, the more subtil only of them get through, whilst those that are weaker and less agitated, are diffused throughout all the other parts of the Body. And therefore we see, that the Heads of many Animals do move after that they are separated from their Bodies, open their Eyes, and bite the Earth, tho' indeed they be destitute of Life.

XIII. The difference between the Animal and Vital Spirits is very small, or to speak properly none at all. For the Animal Spirit is nothing else, but the Vital better depurated, and freed from its grosser Particles in the Brain. Yet they are distinguish'd in this, that the Vital Spirit, being diffused with the Blood throughout the whole Body, doth promote and execute the Vital Functions, viz. Nutrition, Accretion, and Generation: Whereas the Animal Spirits, collected in the Brain, and from thence diffused through the Nerves into the Organs, are chiefly subservient to the Animal Functions, viz. Sense and Motion.

XIV. But here it may be demanded, why these Animal Spirits, do not always flow alike from the Brain into the Muscles; but are very unequally distributed; so as that frequently many more Spirits are sent to some Muscles, than to others?

I answer, That this proceeds chiefly from two Causes: The First is, the unequal agitation and figure of those Spirits, and the Parts that compose them. Which inequality may proceed from the various Dispositions of the Heart, Stomach, Spleen, and all other parts, which contribute any thing towards their Production. Or from the different matters of which the Spirits consist; as may be seen in those that have drunk a great deal of Wine; that the Vapours of the Wine swiftly entering the Blood, mount up from the Heart to the Brain, where they become turned into Spirits; which being stronger, and in more abundance than those that commonly are there, may be able to agitate the Body in many various and wonderful manners. The other Cause is the Variety of those Motions, which are excited in the Organs of the Senses by their Objects. For it may be easily conceiv'd, that the figure and peculiar agitation of the Parts, which constitute the Spirits; or the Action of Objects upon the Organs of the Senses; or the Inclination of the Animal to this or the other Motion, determining the Spirits to enter into this Nerve rather, than into another, cause the Spirit to run into one Muscle, rather than into another: For such is the make or structure of the Muscles, that they swell upon the entering in of the Spirits, and consequently are contracted, and so by drawing those parts of the Body to which they are fastned, effect the motion of them.

i. The Definition of a Brute Beast.

ii. What hath persuaded some, that Beasts make use of Reason.

iii. Brutes cannot express their own Thoughts.

iv. There are no signs taken up at pleasure, to be found in Brutes.

v. Whether Beasts do Discourse together.

gans that are much like ours, why should they not be able to communicate their *Thoughts* to us, as well as to one another? And tho' in some cases they act with extraordinary *industry* and exactness; yet cannot we from thence infer, their *acting* according to *Reason*, for otherwise they would excel us in many things; but only this, that Nature works in them according to the disposition of *Organs*: In like manner as a well-wrought *Watch*, doth more certainly and exactly distinguish the *Hours*, than we possibly could do with all our *Study* and *Endeavour*.

VI.
The Soul
of Brutes
consists in
the Dispo-
sition of
their Or-
gans.

I conclude therefore, that there is no *Soul* in *Brutes*, besides the Disposition of their *Organs*, and the figure of their *Bodies*; and that all their *motions* depend only on the Influence of their *Spirits*, and the due Disposition of their *Organs*. Neither will this seem strange, if we consider, that even all our *Actions*, which we perform, *without minding or giving heed to them*, are produc'd by the same Cause, as *Respiration*, the *Motion* of our *Heart*, the *Digestion* of our *Meat*, and the like. For all these do not appear in the least different from those that are done by *Engins*. This is evident from one Instance, *viz.* that those who fall from on high, stretch forth their *Hands* to save their *Heads*, which they do without any assistance of the *Soul*; but only because the structure of our *Body* is such, that the sight of an imminent *Fall*, being convey'd to the *Brain*, drives the *Animal Spirits* into those *Nerves*, that move the *Arms* and *Hands*: Seeing all this is done without the least advertence in the *Soul*. And thus we see the *Reason*, why a *Sheep* flees at the sight of a *Wolf*, even because the *Light* reflected from the *Body* of a *Wolf*, doth so agitate the *strings* of the *Sheep's Optick Nerves*, and consequently the *Brain*, that thereby the *Animal Spirits* are so driven into the *Nerves*, as to put the *Members* destinated for running into motion.

VII.
This con-
firmed by
several
places of
Scripture.

This *Doctrin* may be confirmed from several places of *Scripture*, which plainly asserts, that the *Soul* of *Beasts* is their *Blood*; *Levit. 17. 14. For the Life, or Soul, of all flesh, is the Blood of it. Gen. 9. 4. But Flesh with the Soul thereof, which is the Blood thereof, shall ye not eat. Deut. 12. 23. Only be sure that thou eat not the Blood, for the Blood is the Soul.* From whence we may evidently conclude, That the *Life* of *Animals* consists in the continual *flowing* of the *Blood* and *Vital Spirits* to the *Brain*, and other parts of the *Body*. And therefore, that we need not search for any other Cause of those *motions* we find in *Beasts*, but the *Influence* of *Spirits*, and the *Disposition* of their *Organs*.

VIII.
How Dogs
light upon
the true
Trace of
the Hare.

As to that Objection, That *Dogs*, after they have laid their *Noses* to two Ways, without any further *hesitation*, betake themselves to the *Third*; we say, that this is not done by them from any *Reasoning*, but only because in that third Way they meet with the *Scent* of the *Beast*, which they did not find in the two other. Neither doth the *building* of *Nests* argue any force of *Reason* to be in *Birds*; because all the *Nests* that are built by *Birds* of the same kind, are all of them built after one and the same manner, which would not be so, in case they acted according to the dictates of *Reason*: For we find that *Men* who act so, build their *Houses* with the greatest variety, according

to the different Suggestions of their *Rational Faculty*.

Neither do we altogether deny *Life* to *brute Beasts*, but freely allow them such an one; the *Activity* whereof proceeds from the disposition and structure of their *Bodies*. Nor *Sense* neither, if it be only taken for a *Bodily Affection* of the *Members*, outwardly and inwardly fitly disposed and aptly joyned, to perform this or the other *motion*. We grant also, that *Beasts* do many *Actions* by *Nature*, like to those which *Men* perform of *Choice* and *deliberately*; but withal assert, that the various and sudden *motions* of *Beasts*, do not argue them to have a *Knowing Soul*, but only a most curious and exactly proportionate compoſure of *Parts*, so as that the least thing is sufficient to put it in *motion*: And that this is possible, we prove by that *Wooden Statue* of *Venus*, which was so Artificially made by *DÆDALUS*, that it could walk up and down: And by the *Wooden Dove*, made by *ARCHYTAS* of *Tarentum*, which did fly about in the *Air*.

You'll say, that *Apes* do many things that manifestly prove them to have the use of *Reason*; as appears in that when they go out to fight, they observe exact *Military Order*, and range their *Armies* as *Men* do; as also, in that they bury their *dead*, and perform many other such like *Actions*, which demonstrate them to be, in some degree, *Reasonable Creatures*.

To this I Answer, That all these *Actions* are performed by *Monkeys* naturally. For as *Watches* point the *Hours*, so *Beasts* perform their *Actions* by *Instinct*: Neither is it a matter of greater wonder, that *Monkeys* do marshal their *Armies*, supposing it to be true what *Historians* relate of them, or bury their *Dead*; than that *Dogs* and *Cats*, after they have voided their *Excrements*, scrape up the *Earth* round about, to cover them from the *Eyes* of *Men*; tho' indeed they seldom do it to any purpose; that is to say, so as to hide them wholly. Whence it is evident, that they act merely by *Instinct*, and without any advertency of what they do; and that there is nothing more in them, than there is in any curious *Clock-work* or *Machin*.

Conclude we therefore, that *Beasts* perform all their *Actions*, whether *Sensitive* or *Motive*, only by the *Texture* and *Disposition* of their *Parts*, without any thing of *Thinking*, tho' in the most imperfect degree imaginable. For if we allow *Brutes* to be endued with *Understanding*, be it never so mean and imperfect, then we cannot deny them the *Privilege* of a *Soul*; and so shall be forc'd to own, that *Monkeys*, *Dogs*, *Foxes*, &c. have *Souls*, as well as *Men*: And if we grant this, we must also allow, that this *Soul* is *Spiritual* and *Immortal*; because *Thinking*, wherein the *Essence* of the *Soul* consists, is not a *Mode* of the *Body*, neither doth in the least depend on it.

Moreover, supposing the *Souls* of *Beasts* to be *Spiritual* and *Indivisible*, it will follow that they are also *Immortal*: Neither is there any *Argument* drawn from the *Light* of *Reason*, whereby we can prove the *Immortality* of *Human Souls*, which will not as well prove the same concerning the *Souls* of *Beasts*. Besides, if we allow *Knowledge* to *Brutes*, we must also make them capable of *Religion*; for to imagin a *Knowing* or *Thinking Creature*,

Creature, without being under an Obligation to obey GOD, and pay Religious Duties to him, is repugnant. For if the *Souls of Beasts* be *Knowing*, they will in the first place know themselves; and it is impossible, but that by knowing themselves they should be led to the knowledge of their *Creatour*. Which Opinions would pave a ready way to *Atheism*.

This *Question* is discuss'd more at large in my *Dissertation, of the want of Sense and Knowledge in Brutes*; to which the Reader may have recourse.

CHAP. XIX.

Of Fourfooted Beasts and Reptils, or Creeping things.

I. The Division of an Animal into Rational and Irrational, is no true Division.

AN *Animal* is commonly divided, in the *Schools*, into *Rational* and *Irrational*, as into two *Members* that take in the whole Nature of *Animal*, and comprehend all its several *Species*. But since *ARISTOTLE* himself doth not approve of this *Division*, because one of the *Terms* of it is a *Privation* of the other; for he declares, that all *Divisions* so express'd are illegitimate; none will think strange if we reject it for the same Reason. For the word *Irrational*, or *Unreasonable*, represents no positive *Idea*, which yet is requisite to constitute the difference of several *Species* or *kinds*. Besides, every *Division* must be express'd in such *terms*, as do explain and lay open the Natures of the things divided; whereas by *Negative terms*, neither any *Attributes* nor *Properties* are declared; and consequently the *Division* of *Animal* into *Rational* and *Irrational*, is to be rejected, and to be reckon'd amongst those which are good for nothing else, but to render the Nature of things dark and obscure.

II. Of Animals, some are Terrestrial, some Volatile, and others Aquatile.

An *Animal* therefore may more commodiously be divided into *Terrestrial*, *Volatile* or *Flying*, and *Aquatile* or *Swimming*, from the places where they live, and the motions they exert.

III. What a Terrestrial Animal is.

We call those *Terrestrial Animals*, that live on the surface of the *Earth*; whereof some be *Four-footed*, that go upon four *Feet*; and others *Reptils*, which wanting *Feet*, do move themselves by *Creeping*. *Fourfooted Beasts* do go by setting their *Feet* one before another, after the same manner as other *Animals* that have 2 *Feet*, or more than 4. To the performing of which progressive motion are generally required *Toes*, *Feet*, *Skin-bones*, *Legs*, which together with the *Nerves*, *Muscles*, *Tendons*, *Ligaments*, *Gristles* and *Membrans*, constitute the *Organs* of *Progressive motion*. The *Bones* belonging to this *Organ* are in several places joyned by *Articulation*, the round *Head* of the one being lodg'd in the Hollow of the other. The *Toes* consist of many *Joints*, to which the *Instep* is joyned, and to that the *Heel*, and the *Bone* call'd *Navicularis* or *Cyboides*; the *Leg* is joyned by articulation with the *Ankle*, and the *Thigh* with the *Hip-bone*, and the *Shank* or *Leg*. *Progressive motion* therefore is performed, when one of the *Legs* standing still upon the ground, the other is thrust out forwards: For the *Legs* are not moved both together, but by turns; so that whilst *Animals* go forwards, the *Muscles* act their several *Parts*, and the *Thigh* is turned in

the *Hip-bone*, and the *Ankle* about the *Leg*.

Whence it follows, that a *Man*, for Example, cannot walk directly in a *Right line*; because as he goes, he rests himself sometimes on one *Leg*, and sometimes on another, so that both his *Legs* or *Feet* are not moved in a *Right line*, but according to 2 *Parallel lines*, which seem to be *Right lines*. It follows also, that a *Man* that goes or walks, doth continually rest or stay himself upon the *Earth*; because one of his *Feet* doth always stand firm on the *Earth*, till the other comes to take its turn: Whence it follows, that it is only the *Foot* that stands still, that makes the *Bulk* or *Trunk* of the *Body* to move forwards. It follows also, that the advancing *Foot* moves as fast again, as the *Trunk* of the *Body*: For seeing that the *Body* advanceth continually, and that the *Feet* advance only by turns, one half of the time must be allow'd for the *Resting*, and the other for the *Advancing*; and that consequently the *Foot* that advanceth, by moving as fast again, doth compensate the delay of its resting.

Amongst *Fourfooted Beasts*, some are greater; as the *Horse*, *Elephant*, *Camel*, &c. Some of a mean Bigness; as the *Dog*, *Lion*, *Sheep*, *Cat*, &c. Some Little; as the *Rat*, *Mouſe*, &c. And of these, some are *Viviparous*, that bring forth living Births; and others, *Oviparous*, that lay Eggs.

Those are *Viviparous*, that bring forth a living and perfect *Animal*; and *Oviparous* are those that lay Eggs, whence an *Animal* afterwards is hatched: Such as are the *Crocodile*, the *Lizard*, *Frogs*, *Tortoises*, whether of the *Land* or *Sea*. It is matter of Wonder, that the *Crocodile*, so vast a *Creature*, which commonly grows to the length of 15 *Cubits*, should proceed from an *Egg* no bigger than that of a *Goose*. *Lizards*, whether those of the greater sort, that are green, or those other that are distinguish'd with shining *Stars*, are propagated by Eggs. The *Tortoise* of the *Earth*, lays Eggs with a *Yolk* in them, which it covers with *Earth*, and by the warmth thereof are hatched; whereas the *Sea-Tortoise* covers hers with the *Sand* of the *Sea-shoar*. *Serpents* also are *Oviparous*, and commonly lay their Eggs in *Horse-dung*, or near to the heat of an *Oven* or *Furnace*, because they cannot hatch them themselves, as *Birds* do.

Amongst *Reptils*, or *Creeping Animals*, are the *Viper* or *Adder*, the *Asp*, and the *Snake*: All which resting upon one part of their *Bodies*, shoot forth and advance with the other. Yet all *Reptils* do not perform their *Progressive motion* after the same manner: For *Snakes* creep by raising their *Bodies* into *Rings*, the former whereof advance, whilst the hinder rest, and support the motion of the other: For by the first of these *Rings* the *Body* is extended; and by the hinder, they contract themselves in more close *Rings*, and as it were gather up themselves. *Earth-worms* also creep by a *Waving motion*, that is, by contracting and unfolding themselves; so that whilst one part of their *Body* rests, the other is moved. To this way of *Creeping* may also be referr'd that of *Snails*, who by means of their glutinous *Moisture*, are fixed to the *Bodies* they creep upon, and by this means advance themselves. The Cause of all these *Motions* are the *Animal Spirits*, which being forceably

forceably, and in great abundance, driven into the Channels of the Nerves and their Valves; and not being able to go back, by reason of the make of those Valves, by distending the Nerves in breadth, and shortning them in length, do move that part, to which they are joyned, by way of traction or drawing.

CHAP. XX.

Of Flying Animals, or Birds.

I. What Birds are, and why the Eagle is said to be the King of Birds.

Flying Animals are commonly called Birds or Fowl; and are distinguish'd from others, for that they fly in the Air. The Eagle is accounted to be the King of them, because of the Strength of his Body, the Height of his Flight, the Sharpness of his Sight, and the Nobleness or Generosity of his Temper.

II. The various kinds of Birds.

There are innumerable Kinds of Birds; and forasmuch as it is next to impossible to speak of all the Individuals of them, I shall content my self to enumerate their Principal kinds, as they are distinguish'd according to their several ways of Feeding. Some are Carnivorous, or such as feed upon Flesh, commonly called Ravenous: And these again are of two kinds, viz. such as have Crooked Bills; as the Eagle, the several sorts of Hawks, &c. Others have a more strait and sharp-pointed Bill or Beak; as the Raven, the Jack-Daw, Mag-Pye, Crow or Rook, &c. Another kind are Vermivorous, or such as feed upon Worms; as the Nightingale, Wood-Cock, Snipe, Wood-pecker, Titmouse, Wren, &c. Another Baccivorous, or such as feed upon Berries; as are the Thrush, Black-bird, the Starling &c. Others are Granivorous, that feed upon Corn and other Seeds: And of these again, some love to be scraping and tumbling in the Dust; as Cocks and Hens, the Peacock, remarkable for his beautiful Tail, the Bustard and Partridge. Others love to wash and dip themselves in Water; as amongst Singing-Birds; the Linnet, the Ligny, the Lark, &c.

III. All Birds go upon two Feet only.

Birds have only two Feet, and those either plain and flat; as Swans, Ducks, Geese, and all Water-Fowl: Or else have their Claws sever'd and divided; as Eagles, Sparrows, Swallows, Pigeons, &c. Some Report, that the Manucodiata, or Bird of Paradise, hath no Feet, but always hovers in the Air, and is never found upon the Earth, but when dead: But Reason and Experience evince the fallshood of this Story. For all Animals stand in need of Sleep, which these cannot take in the Air, especially being always in a hovering motion.

IV. That the Bird of Paradise hath Feet.

And as to those who imagin, that the Birds of Paradise take their Rest hovering in the Air, by reason of the Lightness of their Body, and the Largeness of their Wings and Feathers, and never fall down to the ground till they be dead; I would fain know of these Men, why they do not fall down to the ground when they are asleep, as well as when they are dead; forasmuch as in Sleep all the Senses are lock'd up, and all motions of the Members cease? But that all Doubt may be taken away in this Point, let us consult such as have been Eye-witnesses. ANTONY PIGAFESTA, a Famous Traveller, in the Diary of his Naviga-

tion assures us, that they have Legs of a Hand-breadth long, and that they can go and fly like other Birds: And that none but Strangers suppose them to be without Feet; because the Inhabitants, whenever they take them, cut off their Feet, and take out their Guts, casting them away, and then expose them to the Sun to dry, which they then sell to Strangers, or stick them in their Caps or Helmets, for Ornaments sake.

Birds are the Product of Prolifick Eggs, that is, such as have been invigorated by the Male, and presuppose the fruitfulness of the Female. For as an Egg without the Cock's Treading is addle; so the Hen, by producing that Cavity which is in the Yolk, doth contribute likewise to the fruitfulness thereof. This will be the better understood by distinguishing the Egg into 2 Parts, viz. into the Yolk and White. The Yolk is of a yellow Colour, tending to Red, as being nourished by Blood; which is manifest from those small Veins, that are dispers'd throughout its outward Coat or Membran. Besides this Coat, there is also another very thin one, by means whereof the Yolk hangs to the Cluster, so called, and covers the whole Yolk, and conveys Veins and other Vessels to it, by means whereof the Alimentary Juice is transmitted. The White is the more Outside-part of the Egg, yielding copious Nourishment, but somewhat of a colder Temperament, and not so easie of digestion as the Yolk: It consists of a fibrous or stringy Matter, and therefore is easily coagulated, growing hard with the least heat. At the Broad-end of the Egg a little Hollow is found, where the Chicken begins to be formed; and this proceeds from the Hen only. Besides these, there are found in Eggs 2 Specks, call'd by us the Cock's Threadles, in which the plastick or formative Virtue of the Egg is supposed to consist, according to the Opinion of the Common People; but it is a Mistake, seeing they are found in all Eggs, as well in those that are addle, as the prolific. An Egg therefore becomes fruitful, when the Seed of the Cock is joyned to that Hollow or Scar in the Egg before-mention'd, which proceeds from the Hen. For it is not to be question'd, but that the Seed of the Cock doth reach the Womb of the Hen, and as it were, takes root in the Cells thereof; whence the Rudiment of the Chicken afterwards buds forth.

V. Birds proceed from Eggs.

When the Hen therefore sits upon the Egg, and excites the Bud, or prolific part of it by its heat, the strings or fibres become dilated or extended into several concentrical Rounds or Circles, and the Chicken becomes formed by degrees. For the second day of the Hens sitting, the Hollow that is at the broad end of the Egg, begins to be dilated, and becomes a Bubble, the thinner particles of it being exhaled by Heat, those only remaining that constitute that most clear water, wherewith the Bubble is filled. On the Fourth day a Purple Spot, or Reddish point appears, which is the Rudiment and first beginning of the Heart, and from whence a short time afterwards proceed many little Veins of the same colour, but almost invisible by reason of their fineness and subtilty, and which afterwards end in the Umbilicary or Navel Vessels. On the Fifth day there appear in this Rudiment of the Heart, 2 Ventricles, and as many Ear-lappets; and because the Ventricle or Right Cavity is contracted,

VI. The Progress of the Forming of a Chick, the 1, 2, 3, 4, and 5th Day.

tracted, when the *Ear-lappet* that is joined to it is dilated, they seem to be 2 *Bladders*. The same day, there appears something in the likeness of a *Worm*, joined to the little *Vein*, to which the round little *Body* is annexed, but bigger than it, being distinguished into 4 *Bubbles* filled with a most clear and *Crystalline Liquor*. Which 4 *Bubbles* do represent both the *Eyes*, the *Brain*, and the *Cerebellum* or hinder part of the *Brain*.

VII.
What is formed in the Chick the succeeding days.

On the *Sixth day* the *Feet* and *Wings* of the *Chicken* are formed, the *Coats* and *Membrans* of the *Eye* begin to appear, as likewise the first beginnings of the *Lungs* and *Liver*. Also the *Bill* or *Beak* and all the *Guts* and *Inwards*. At the same time the *Chicken* begins to move it self a little, and to lift up its *Head*. Then also the *Rudiments* of the *Bones* begin to be formed, appearing like so many thin *Spider Webs*. On the *Seventh day* all the parts begin to appear more distinct, and so encreasing every day till the *Tenth*, wherein all its parts are compleated. For the *Head* then appears greater than all the rest of the *Body*; and the *Eyes* bigger than the *Head*; and in this state the *Chicken* swims on the *Colliquamentum* or dissolved *White* of the *Egg*. After the *Fourteenth day*, all its members appear still more distinctly: for then it begins to be covered with *Feathers*, the inwards begin to be hid, and the hinder part of the *Brain* begins to be pent up in the *Skull*; the *Chicken* begins to *Peep* or *Cheep*, and being no longer able to bear the straightness of his pent up *Room*, after having first consum'd the *White*, and afterwards the *Yolk* also, it breaks through the *Shell* and comes forth.

VIII.

It is probable that a Chick and other Animals, are not formed by Parts, but all together.

This is the Progress our *Eyes* discover in the forming of a *Chicken*, because it appears such to the unassisted *Eye*. But when we take in the Verdict of the *Microscope*, as *MALPIGHIVS* did, there will appear to us in every Fruitful or Prolifick *Egg* (for in the *Addle*, no such thing is to be found) before the *Incubation* of the *Hen*, the first *Rudiments* of the *Chicken*; in like manner as sometimes, even without the assistance of a *Microscope*, we can discern the first *Lineaments* of a *Plant* in the *Bud* of it. This is very evident in a *Tulip*, for if in the *Winter* time we view the *Bud* of it, either with a *Magnifying Glass*, or only with our bare *Eye*, we shall not only see the *Leaves*, which afterwards turn *Green*, but also those that constitute the *Flower* of the *Tulip*, with the *Triangular* part of it enclosed in the *Grain*, and last of all those little 6 *Pillars*, which surround it, at the bottom of the *Tulip*. And accordingly it seems probable, that as a *Flower* contains a *Flower*, so an *Animal* contains another whole and compleat *Animal*, tho' sometimes the same be not discoverable, but with the assistance of a *Microscope*.

IX.

How Birds do fly in the Air by the Help of their Wings

Birds with the help of their *Wings*, keep themselves up, and move in the *Air*; because the *Air* resists the swift agitation of their *Wings*, and opposeth their descent or falling down. For tho' the *Air* be very pliable, and ready to give way to other *Bodies*, yet it indeed makes a great resistance, and like the *Water*, opposeth the entrance even of *Heavy Things*. For we see that when *Boyes* skim *Stones* along the surface of a smooth *River* or *Pond*, the *Water* resists them, and makes them by several rebounds leap up from the *Water* which opposeth their entrance. Yea many times

the *Bullets* discharged from great *Guns* are seen to graze along, and rebound from the *Water*, so that sometimes men that are walking on the *Bank* or *Shoar* are sometimes wounded and killed, by *Bullets* so rebounding from the *Water*. And in the same manner are *Birds* borne up in the *Air*, and tho' they be heavier than it, yet by the spreading and continual beating of their *Wings*, they are supported in the midst of it.

To the flying of *Birds* 2 things are requisite, X. First the spreading of their *Feathers*, the single *Hairs* whereof are so intangled, that the *Air* cannot enter through them without some difficulty, from whence the resistance ariseth. Secondly, the expansion of their *Wings*, and their beating of the *Air* with them, and that either leisurely, as *Kites* do, or more frequently like *Doves*, or very fast as the *Felshare*. And accordingly by the Prevalence of this resistance, the force of *Gravity* is overcome, and the *Body* of the *Bird* continues poised in the *Air*.

Moreover forasmuch as *Birds* do not only press the *Air*, and hover in it, but also move up and down; it is necessary that the *Wings* which bear them up, be thrust backwards; that so by the resistance of the *Air* behind them, they may be forwarded in their progressive Motion. For the structure of a *Birds* *Wings* is such, that the hollownes of them forward, and their prominence backward, do both concur to beat back the *Air*. A Resemblance whereof we meet with in those that swim, who if they do only press the *Water*, with their *Belly* and *Hands*, without beating it back with their *Feet*, they cannot move forwards; no more than a *Ship* can advance if the *Water* be only divided by the *Oars*, without they be thrust or moved backwards. *Birds* therefore in order to their moving forwards, and passing this way and that way, must beat back the *Air* behind them. And whereas some *Birds* fly much more swiftly and strongly than others, as the *Swallow*, the *Pigeon* and the long-winged *Hawks*; the reason thereof is, either the more advantageous make and frame of their *Wings*, or the strength of their *Muscles* wherewith they move them, or the proportion of *Heaviness* or force that is in their *Bodies*.

We must take notice that *Birds* do not move in the *Air* like a *Ship* or *Boat* in the *Water*. For a *Boat* or *Barge* being driven by *Oars* is pushed forwards, whilst the *Oars* thrust against the *Water*, which resists, in a manner, as much as if all its parts were in rest. Neither do *Birds* shake their *Wings* towards their *Tails*, as *Oars* drive the *Water* towards the *Stern*, but do bend them downwards. The *Tail* of *Birds* serves to incline their flight upwards and downwards, but not side-ways, neither is it to them instead of a *Helm*, as is commonly believed; for it doth not perpendicularly cut the *Air*, as the *Helm* of a *Ship* doth the *Water*, but hath an *Horizontal Situation*; and when a *Bird* turns side-ways yet his *Tail* continues straight stretched out; and therefore we see that *Birds* fly tho' their *Tails* be cut off. *Birds* therefore are poised in the midst of the *Air*, as a *Ship* in the *Water*, to wit in the Center of their *Gravity*. And like as a *Vessel* that hath his *Oars* more swiftly plied on the right side, turns about the Center of its *Gravity* towards the left; So likewise a *Bird* whilst he beats the *Air*, chiefly and mostly

water

The fish are found in the water, and are of various sizes and shapes. Some are large and powerful, while others are small and delicate. They are all adapted to their environment, and are found in various parts of the world. The fish are also of great value to man, as they are a source of food and of many other products. They are also of great interest to the naturalist, as they are a part of the great system of nature.

mostly with his Right *Wing* towards the *Tail*, his fore-part by this means is turned towards the Left. As when those who swim, by bending their Right Arm, and spreading their Right Hand, drive the *Water* towards their Feet; and by the same means turn themselves about towards the Left-hand.

XIII. And that we may the better apprehend how the Tail of Birds serves them to turn downwards or upwards: Let us suppose a Bird A B, whose Center of Gravity is C, flying Horizontally from G to F, and that in flying he rear his Tail B H; this supposed, it is manifest, that the Air, which resists the Tail B H, makes the whole Body of the Bird turn about the Point C, that it may take the situation L K, wherein the Head raiseth it self from A to L; and on the contrary, when the Tail is turned downwards to B I, the resisting Air makes the Body of the Bird to turn about the same Point C, for to take the posture N O, wherein the Head of the Bird doth lower it self from A to O.

Figure 60.

C H A P. XXI.

Of Swimming Animals, or Fishes.

I. **F**ishes, because they live in the *Water*, and move themselves by way of *Swimming*, are called *Aquaticles*. The most bulky of these, and as it were the Prince of them all, is the *Whale*, very common in the *Indian Sea*, to whom *PLINY* assigns the largeness of 4 Acres, which make out in length 960 Foot. *PARÆUS* makes mention of one that was taken in the River *Schelde*, 10 Miles from *Antwerp*, in the Year 1577, which was 58 Foot long, 16 Foot high, and its Tail 14 Foot broad; the distance from his Eye, to the entrance of his Mouth, 16 Foot; his Under-Jaw was of 6 Foot furnish'd with 25 Teeth, to which in the Upper-Jaw were answering so many Cavities, wherein, upon the shutting of his Jaws, they were hid. A *Whale* is distinguish'd from other Fishes, in that it hath, besides Lungs, Kidneys, Arteries, Bladder and Genitals, a great Pipe in the fore-part of its Head instead of Gills, by which with great force it spouts again out the *Water* it receives into its Body.

II. There be many differences of Fishes taken from the coverings of their Bodies, or from the Place they delight in. With regard to the Place some are Sea-fish, others River-fish, and others such as delight in Lakes and Ponds. With respect to their covering, some are Scaly, some covered only with a Skin, and that either with a smooth, or rough one. Amongst Sea-fish some are called *Littoral*, because they delight in the neighbourhood of the Shoar, such are amongst the Scaly Fishes the Roach, and the Trout, &c. and of the smooth skin'd Fishes, the Mackrel and the Eel; others are called in Latin *Saxatiles*, because they delight in Stony Places, as the Gilt-head, common in the Sea of Crete, the Gudgeon, the Hornback, some pass from the Sea into Rivers, as the Salmon, the Lamprey, &c.

III. Some have been of the opinion that Fishes were not generated by Copulation, but that the Female swimming before did scatter her Spawn, which the Male following her did impregnate, by pouring his Milt upon them. But this is a mistake,

for Fishes do copulate, which would be altogether in vain, in case the foresaid opinion were true. Besides how can we conceive that the Spawn or Eggs of the Female Fishes, should be sprinkled with the Milt of the Males, seeing that it would by mixing with the water lose all its virtue. Neither can we build much upon *ARISTOTLES* Authority in this Case, forasmuch as he doth not prove it by any Experiment. And in his 3d Book de Animal. Cap. 7. he owns the thing to be doubtful. Fishes therefore are generated by Copulation as all other Oviparous Animals are: but to what purpose would this Copulation be, if the Male doth not by his Emission render the Eggs of the Female fruitful? Besides, it is observed that the Males abound with Milt at the same time that the Females abound with Spawn or Eggs, and that then is the time of their Copulation. And it is at the same time that the Males follow the Females, not that they may besprinkle the scattered Eggs, but that by their repeated Copulation, they may impregnate other of the Females Eggs that are ready to be Spawn'd: as we see that to the same end a Cock doth often tread the Hen: for seeing that Fishes, above other Animals, do abound in Eggs, they can never all of them be impregnated by one act of Copulation. From this way of Generation we are to except the Dolphin and the Whale, which are not Oviparous, but bring forth living Births, and therefore their way of Copulation is different, and their Breasts are filled with Milk, contrary to the nature of other Fishes.

Amongst Fishes there be many that are called Monsters, as the Hippopotamus or the River Horse, because it resembles a Horse, yet not so much in Figure, as in its Bulk. For it hath Ears like a Bear, and a Mouth wider than that of a Lion, with very great Eyes, and a very short Neck, or none at all; it hath the Tail of a Swine, with short Feet, and a divided Hoof like a Hog. *ARISTOTLE* describes this Animal Lib. 2. Hist. Animal. thus; The River-horse, saith he, which Egypt brings forth, hath the Mane of a Horse, a round Hoof like a Pipe or Tube, a flat Snout, and an Ankle like those that divide the Hoof in two, Teeth somewhat prominent and sticking out, the Tail of a Swine, the Voice of a Horse, the bigness or bulk of an Ass; the thickness of his Hide being such, that they make Hunting-staffs of it; and all the inward parts of it resembling those of an Ass or Horse; which is the account *PLINY* gives us from *Aristotle*. The Sea-calf is also accounted a Sea-monster, for it differs from all other Fishes in the shape of its Body, inasmuch that *ARISTOTLE* ranks it amongst 4 footed Beasts. This Monster hath short Arms, without any Elbow; and for the rest hath some resemblance with our Bodies: It consists of many Bones, and is covered with a thick Hide, full of dark coloured Hairs, drawing towards an Ash-colour: the Head of it is but little with respect to its Body, and its Neck is long, which it can stretch out, and draw in at its pleasure; it hath no Ears, but instead thereof only some open holes; its lower Jaw resembles that of a Wolf, but the upper is much broader than those of the same Animal; his Nostrils are very like that of a Calf, his Teeth like those of a Wolf, and his Eyes are of a changeable and uncertain colour. A Thornback also is a very deformed

IV. Many Monsters are found amongst Fishes.

and

and monstrous *Fish*, but being so commonly known, there is no need to insist upon the Description thereof.

V.
The Peripateticks following their Master, deny all Respiration to Fishes.

Forasmuch as *Respiration* is ordained by Nature for the Cooling of the Blood, and to send away the vapours and stinky steams proceeding from the Body, which would otherwise stop the Blood from entering into the left Ventricle of the Heart, if they were not emitted out; it hath been a question controverted amongst the Antients, whether Fishes and other Animals that want Lungs do breathe or no. This is commonly denied by the Peripateticks upon their Masters Authority, who by no means will allow any Respiration in Fishes.

VI.
Fishes breathe by the drawing in, and letting out of their Breath.

But our Modern Philosophers and Physicians, tho' they cannot allow Fishes such a Respiration as is performed by the Contraction and Dilatation of the Midriff, and Lungs, since they take for granted that Fishes (except Whales and Dolphins) have no Lungs, yet neither do they deny them such a Respiration as consists in the drawing in of Air or the like Halituous Matter, in order to the cooling of their Blood. Pliny joins with this opinion, Lib. 9. Cap. 7. because, saith he, instead of Lungs they have other Organs for Breathing, and instead of Blood some other Equivalent humour. Neither do we want reason wherewith to back this opinion; for the end of Respiration is the cooling of the Heart, and the cherishing and refreshing of the Vital Spirits: now both of these are necessary to the preservation of the Life of Fishes. Besides, why were Gills given to Fishes, but that through them the Water, either alone by it self, or mingled with the Air, might be conveyed to the Heart, and afterwards cast out again? But who will not be convinced that Fishes must take in the Air by Respiration, when we find that they die without it? For if Fishes be shut up in a Vessel with a narrow Mouth, full of Water, they may be kept alive there for many Months, if the mouth of it be kept open, but if it be shut up they die immediately, which would never be if they did not stand in need of Air, or if Water alone were sufficient for the cooling of their Heart.

VII.
The Respiration of Fishes proved by Experiment.

And what is very observable herein, is that as soon as the Vessel is stoppt the Fish get themselves up to the top of the Water, to take in some Air, which they do not do whilst the Vessel is open, but play up and down the Vessel. Wherefore RONDELETIUS in his 4th. Book of Fishes, Cap. 9. saith, that the greatest Fishes, and those that have Lungs do draw in the Air together with the Water; and cast it out again by the same Pipe, whereby they draw in their Breath: and in this manner do Whales, Dolphins and Whirlpools (a Fish so called) draw their Breath. Others perform this Respiration by the Lungs, only without the assistance of a Pipe to cast out the Water, as Sea Tortises or Tortles, and those of Rivers and Lakes; as also Sea Calves, who have wide Nostrils, and a very strait Windpipe, by which means they spout out the Water again through their Nostrils, but retain the Air. All other Fishes that have either open or closed Gills, do with them draw in the Air, and at the same time cast out the Water. Oysters which are covered only with a very thin Skin, seem to breath through the Pores thereof. And in a Word, all Animals living in the Waters, according as their heat is more intense or

remiss, or according as their Spirits are more or less copious, so they have a several way of Respiration.

Neither indeed is there any Animal in the Universe, which is not preserved by the Air, as is manifest from the Pneumatick Engine of Mr. BOYL, in which whatsoever Animals are put, excepting only Oysters and Crabs, die immediately. The same thing is yet more evident in Insects, in whose Rings & Holes are discernible; which when they are stoppt with Oil or any other glewy or clammy Liquor, so that the Air cannot have its free entrance, the Animal presently begins to languish, and after some Convulsive Motions expires.

But you will object with ARISTOTLE, that if the Air do penetrate the Water, and reacheth to the very heart of Fishes; why then for the same reason a Man may not as well fetch his Breath under Water?

I Answer, that the cause thereof is, because Man living in the Air, doth continually attract it very copiously, whereas that portion of Air which is in the Pores of the Water, is very inconsiderable if compared with that which Men naturally take in, and therefore is not sufficient to answer that end. Moreover, for want of Air the Water is drawn into the Lungs, and there being no way to cast it out, because of other Water still coming in, it oppresseth the Heart, and choaks a Man. Whereas Fishes are furnished with Gills, by the help whereof they cast out the Water, nor suffer it to come to their inwards, but the Air only, whereby the heat of their Heart is allayed and their Vital Spirits preserved.

The Swimming of Fishes, doth somewhat resemble the Flying of Birds: for their Fins are instead of Wings, as also their Tail. These consist of Membranes, joyned together by long Fibres, and which can be distended or contracted and turned every way.

There are in all Fishes, Bladders full of Air, which according as they are compressed or dilated, so the Fishes are poised on the waters. For it hath been observed that a Fish, whose Airy Bladder had been broken in the empty Recipient of the Pneumatical Pump, could never, during a whole Months time, that it lived in a Fish-pond, rise to the top of the water, but was fain to keep at the bottom of it. According therefore as Fishes do contract or dilate the said Bladder, so they encrease or diminish the bulk of their Body, and accordingly also do diminish or increase their weight; and by this means they can either dive to the bottom of the water, or mount to the top of it. Much after the same manner as Glass Bubbles, or Figures hanging in a Glass Tube full of water are made to go down to the bottom, or to come up to the top at pleasure.

A Fish by moving of her Tail advanceth swiftly, and rests when that motion ceaseth; so that the shaking or turning of her Tail is the chief cause of her motion; for when she shoots forwards directly with her Belly, she turns the other half of her Body sideways, and whilst she strongly beats the water with her Tail, she at the same time moves her body forward, much after the same manner as a Boat, which the Oar drives forwards, whilst it obliquely strikes the water that is behind it. A Fishes Tail also performs the use of a Helm, by turning the Fishes course to the Right or Left.

Thus

VIII.
The Life of all Animals is preserved by the Air.

IX.
Why a Man cannot breathe under water.

X.
How Fishes swim.

XI.
What instruments the Fishes use to move themselves in swimming.

XII.
What use the Fishes make of their Tails.

Figure 61.

Thus by Example, the Fish A B C, that is about to move it self, turns its Tail D F C, to the Right G, and that so, that whilst the part moved B C, turns about its Center B, it doth not continue strait, as the Ray of a Circle; but bends it self 2 several ways towards B, viz. by advancing her side F towards the Right-side G, and by turning the utmost part of her Tail D to the Left, by which means the Water does but little resist her. Afterwards, her Tail turning again by the force of the Muscles, it drives the Water from G towards F, as an Oar would do: Whence it follows, that the Fish must advance from C to A, and then its Tail being again moved from C to H, as we have said that it was moved from F to G; and being afterwards turned again, it drives the Water from H towards C, and by this means makes the Fish advance in a strait Line from C to A; by the repeating of which motions of her Tail, the Fish continues swimming along.

XIII. Of Flying Fishes.

Amongst Fishes there are some that fly; as the Sea-Swallow, and the Sea-Hawk, so called, which have fins joyned to their Gills of that length, that they reach almost to their Tails. These sometimes fly in such vast Shoals in the Air, as PLINY tells us, that they encumber Vessels in their Course, and sometimes make them sink. But they never fly high in the Air, but keep close to the Surface of the Water; so that some question, whether the Sea-Hawks fly or swim. They continue thus hovering in the Air as long as their Fins are wet; and as soon as they are dry, fall down again into the Water.

CHAP. XXII.

Of Insects.

I. Four kinds of Bloodless Animals.

ARISTOTLE reckons up 4 kinds of Bloodless Animals: Such as are soft, as the Polypus or Pourcoute, the Cuttle-fish, &c. Such as are cover'd with a hard Shell, and difficult to be broken; as the Crab, Lobster, &c. Such as are cover'd with a Shell that is brittle and easily broken; as Cockles, Periwinkles, and other small Shell Fishes; and of these there is so great a variety, with respect to figure and colour, that they cannot all of them be reckon'd up. And, Lastly, Insects, so called from the Intersections and Divisions of their Bodies; which also are styled by ALBERTUS MAGNUS, Annulata, as consisting of several Rings.

II. The great variety of Insects, with relation to the place wherein they live.

The Variety of Insects is very great, with respect to their Food, the quality of their Bodies, and the Place in which they live. As to the Place, Hairy and Red Worms are generated in the Snow: Fire-flies, which some suppose to be Crickets, in the Fire. Which I have spoke of in my History of Nature, in the Part that treats of Animals. In the Sea, the Sea Scolopendra, and Water-Flea: In Fresh-waters, Leeches, Horse-Leeches, &c. In the Earth, Earth-Worms; between the Barks of Trees, Wood-Lice; in Fig-trees, a certain Worm called Ceraffes; in the Service-tree, Red and Hairy Worms; in Vines, the Worms called Butyri, &c.

III. The difference of Insects, with respect to their Parts.

As to their Parts, some Insects have no feet, others have. All Worms are without feet, as well those which are generated in the Earth, as Earth-Worms; as those that breed in the Bodies of Ani-

mals, especially in their Guts. The Veevil, that breeds in Corn, another that is found in Beans, &c. Amongst those that have feet, some have 6; as the Pismire, the stinking Bug, the Flea and Louse: Others have 8 feet; as the Scorpion and Spider: Some 12; as that of Canker-worms, which is called the Geometrician, because it hath 6 feet in the fore-part of his Body, and as many in the hinder-part, and raiseth up his Back in the form of a Bow or Arch, going like one that measures Land: Some have 14 feet; as all other sort of Canker-worms, which in the fore-part of their Bodies have 6 feet, and 8 in the hinder part.

As to the Generation of Insects. The general Opinion formerly hath been, that they were not produced by a true Generation, but deriv'd their Pedigree from the Corruption of Animals, or other things. But Experience hath informed us of the contrary: For if we put a piece of Flesh into a Bottle, and then stop it; the Flesh shut up there will never breed any Worms; but if we leave the Bottle unstopt, it will be full of Worms in less than 4 days, in the Summer time. We find also, that Butter-flies, after Copulation, do lay a vast number Eggs, whence Canker-worms are hatched.

So that we may rationally conclude, that all those Animals which seem to breed of themselves, and are found in Cheese, in Fruits, in Trees, in Flowers, and in Men, are the product either of Eggs, or such like Seed, left by other Animals. The production and process of which, may be fully illustrated by the Generation of a Canker-worm. For Canker-worms, as all other Worms, are generated from a Seed, or from the Eggs of Flies or Butter-flies, which by the heat of the Sun are hatched into Worms; which, after they have changed their Skins several times, turn to Canker-worms, and then to Aurelia's or Bodies without motion, cover'd with a Shell, and in which no distinction of Parts appears; and these again are turned into Butter-flies, or Flies. For it sometimes happens, that from the same Canker-worms and Worms, Aurelia's do proceed; whereof some are turned into many Flies, and others into single Butter-flies. Out of a Worm therefore a Canker-worm is formed; because, as a Plant doth not immediately bring forth branches, flowers, leaves and fruit, but by degrees, and each of these in their due Season; so these Worms, by degrees, arrive to a further measure of perfection. For certain it is, that these Worms do often change their Skins. A Canker-worm therefore is changed into an Aurelia; because the Trunk of its Body being swoln, and its Members almost formed, it so happens that all his Coats and Coverings begin to grow dry, and fall away of themselves; as Flowers fall from Trees, and Feathers from Birds; which when the Aurelia perceives, it either wraps it self in a Leaf, or with a glutinous Liquor proceeding out of its own Body, it most artificially weaves a strong Covering for her self; where it continues shut up, as in an Egg, till it receive new Members, Head and Wings, and so become turned to a Butter-fly.

And the same is to be said of all other Insects, that have Wings. For Flies proceeding from Eggs or Seeds, by some Changes as have now been mentioned, do attain to the Perfection of their Nature; for first they are Worms, then they turn to Aurelia's, and out of them Flies do proceed.

X x x

IV. Of the Generation of Insects.

V. All Insects proceed from Eggs.

VI. Flies and other Insects, proceed from Worms.

ceed. For as a *Canker-worm* is to a *Butter-fly*, the same respect or relation a *Worm* hath to a *Fly*. And so likewise *Lice*, *Fleas*, *Bugs*, and other such like *Insects*, are generated of *Eggs* or *Nits*, or of other *Insects* already produced. For all those *Animals* which are commonly said to be generated out of *putrid Matter*, that is the Corruption of other things, are produced by *Copulation*; as we see that *Flies* do *Copulate* when *August* is past, and thereupon they bring forth not *Worms*, but *Eggs*, which are found in great abundance upon the *Leaves of Trees*, in the appearance of a *black smutty Matter*; which afterwards, by the *Heat of the Sun* are hatched into *Worms*, but such as are immoveable, and answering to the *Aurelia's* of the *Canker-worms*, which afterwards are changed into *Flies*.

VII.
How Canker-Worms become changed into Butter-flies.

This *Metamorphosis* is not so difficult to conceive, if we suppose that those *Parts* which seem to be produc'd anew, are only made visible, as having before been hid. For when *Canker-worms*, by Example, become *Butter-flies*, it is easie to conceive, that the *wings* and *feet* they get, and which makes them appear to have been changed into new kinds of *Things*, are not newly produc'd *Parts*, by obtaining of a new *form*, which they had not before; but that these *Parts* were indeed before, and only wanted a sufficient *Magnitude* to render them *visible*. After the same manner as it happens to *Plants*, where the *flowers* and *fruits* do not unfold themselves, but by degrees, and some time after the *Leaves*; tho' all these *Parts* be at once actually together in the *Plant*, before they appear to be there. *Insects* therefore, as well as other *Animals*, are generated by the Coition of *Male* and *Female*; which latter lays *Eggs*, out of which afterwards their *Young* are hatched by the *heat of the Sun*.

VIII.
How the Eggs of Insects are preserved in the Winter Season.

But here it may be demanded, How these *Eggs*, whence we have said that *Canker-worms* and *Flies* are hatched, are preserved all the *Winter* over, so as that the next *Year* they may produce *Animals*. *ALDROVANDUS*, in his *Treatise De Insectis*, supposeth that those *Eggs* only are preserved, which are in those *Leaves* that are hid in the *Cavities* of the *Barks of Trees*, where they cannot suffer any damage from the *Injuries of the Air or Weather*. Thus I my self, saith he, have observed *Eggs* fastned to the hinder part of *Fig-Leaves*, whence, towards the End of *August*, little *Canker-worms* did proceed. They were wrapt up in a thin *Downy substance*, to preserve them from being hurt by the *Ambient body*; which *Canker-worms* afterwards falling down, were not dash'd against the *Ground*, but continued hanging in the *Air*, like *Spiders*, by a very fine *Thread*. When they lay their *Eggs* on the Under-side of *Leaves*, they do so fold the said *Leaves* that no *Rain* can hurt them, making as it were a *Covert* over them. I have also twice taken notice, that a *Canker-worm*, which I found amongst *Cabbage-Leaves*, did first lay *yellow Eggs*, wrapt up in a thin *Downy matter*; which, after she had laid them, became changed into an *Aurelia* of the same Colour, as she had before when yet a *Canker-worm*, viz. *yellow, green and black*; and, which seem'd strange to me, afterwards *flying Animals* proceeded from these *Eggs*, so very small, that they could scarcely be discerned by the *Eye*; such as

are commonly found in the *Bladders* that are on the *Leaves of the Elm-tree*. So far be. Tho' there be some *Country-men* that tell us, That these *Eggs* are not only kept between the *Barks of Trees*, but that many *Leaves* fill'd with the *Eggs of Butter-flies*, are many times found hid in the *Earth*, where they are preserved all the *Winter*, till by the *heat of the Sun*, at the return of *Spring*, they be hatched into *Insects*.

CHAP. XXIII.

Of the Death and Destruction of Animals.

AS in the *First Chapter* of this *Part* we reduc'd the *Notion of Life* to 3 *Heads*; so here, that we may understand how *Animals* may be said either to *dye* or *perish*, 3 sorts of *death* or *dying* are to be distinguish'd. First, There is a *Death of Simple Annihilation*, which is oppos'd to the *Life of Simple Existence*: Secondly, *Cessation from Operation*, which is the *Death* that is oppos'd to the *Life of Actuous Existence*: And, Lastly, the *Separation, or Dissolution of one part from the other*, which is oppos'd to the *Life of Existence with another*. By the *first* manner of *Death*, those things *dye*, which by ceasing to exist altogether, fall into nothing: Things *dye* the *second* kind of *Death*, when they cease to act: And the *third* way, when their *Parts* are separated, and exist distinctly from one another. But forasmuch as no *Substance* can be annihilated, it remains only for us to enquire, how *Animals* come to cease from all *Operation*, and how the connection of their *Parts* comes to be dissolved.

But before I come to Treat of these, I shall first lay down this Truth, That *Death* is as much the intention and design of *Nature*, as *Life* is. For who will say, that *Corruption* is less Natural, than *Generation*? For tho' nothing seems to *dye* without reluctance, and some force put upon it; yet is not *Corruption* therefore to be accounted less Natural or disagreeing with the *Laws of Nature*. For tho' *Corruption* be contrary to particular *Nature*, as procuring its *Destruction*; yet is it very consentaneous to *Universal Nature*, which never undertakes the *Generation* of any thing, without the fore-going *Corruption* of another, as not being able to create, or to produce a thing out of *Nothing*. Wherefore seeing, that the *Beauty and Perfection of the World* consists in *Variety*; and that it is much more for the *Dignity of the World*, that many things in process of time should appear and act their *Parts* on this great *Theatre*, than to represent always one and the same *Face* of things: The *Divine Wisdom* hath so order'd it, that *Old things* should make way for *New ones*; and that those things, which for some time have acted their *Parts* on the *Stage of the World*, should withdraw to make room for others. But if any one shall think it a hard case for him to leave this *World*, let him consider, that he himself could never have enter'd this *World*, but by others making room for him: For if all our *Ancestors* had been *Immortal*, they would have been increased to that number, that there would have been no place left for their *Posterity*.

Having

III. Having said thus much to comfort us, and make the state of our Mortality more tolerable, we now assert that *Death* happens to *Animals* by the extinguishing of the *Fire*, that is in their *Hearts*. For in the *Hearts* of all *Animals*, as long as they are alive, there is a kind of *Continual Heat*, which we before call'd a kind of *Fire* that is *not* without *shining*, and which *Physicians* do own to be the *Bodily Principle* of all *motion* in the *Members* of *Animals*. And therefore no wonder, if this being once extinct, *Life*, *Sense* and *Motion* be likewise destroyed.

IV. For tho' this *Native Heat* be strong and efficacious at the beginning, yet in the process of Age it loseth strength, and grows weaker and weaker; so that *Animals*, after they are come to their full growth, are at a stand, and soon after their strength decays; and at last, by the defect of this *Heat* they *dye*; as the *flame* of a *Wick*, for want of *Oil* is extinguish'd. But yet there is a difference betwixt the *flame* of a *Lamp*, and the *Life* of *Animals*; because the former is continued, as long as it is supplied with *Oil*: But the *Life* of *Animals* cannot be maintained by perpetual *Aliment*, because *Animals* *dye* not for want of *Aliment*; but because their *Heat* grows so weak, that it can no longer change the *Food* into the *Substance* of the *Body*. And therefore *Physicians* tell us, that the *Heat* which *Nature* hath afforded us, for the *Maintenance* and *Support* of our *Bodies*, doth conspire their destruction. For tho' it preserves us, forasmuch as by feeding upon *Moisture*, it affords strength and vigour to our *Members*; yet at the same time it also lays the foundation of our *Destruction*, whilst by continual consuming of our *Moisture* it self becomes debilitated, without restoring, as much as it doth consume: And accordingly it follows, that when the *Moisture* is consumed, the *Body* must consume and waste likewise, and the *Heat* it self be extinguish'd.

V. Now that *Death* proceeds from the decay of *Heat*, daily Experience teacheth us in *Dying* persons: For we find that the *Extream* parts of their *Body* first begins to grow cold, till at last their *Breast* and *Heart* it self be deprived of it. For since the *Heat* which is dispers'd through the whole *Body*, proceeds from the *Arteries*, inasmuch as by thinning the *Blood* that is in them, it generates those *Spirits* which communicate *Motion* to all the *Parts* of *Man's* *Body*; it must of necessity follow, that when the *motion* of the *Arteries* and *Heart* grows weak and languishing, this *Weakness* must first affect the *Capillary Veins*, as being both small and weak, and at the greatest distance from the *Heart*, the *Fountain* of *Heat*.

VI. It may be you will Object here, That some *Animals*, after that their *Heart* hath been taken out of their *Bodies*, have notwithstanding performed the *functions* of *Life*. *ARISTOTLE* alledgeth the Example of a *Tortoise*, which when his *Heart* is taken out, doth nevertheless walk about, though he be but small, and of a weak and slow *Body*. Some *Historians* also make mention of some persons, who have spoke after that their *Heart* hath been pluck'd out of their *Bodies*. Now, whence could these *Actions* or *Words* proceed, if the *Heart*, by its *beat*, were the sole *Principle* of all *Bodily motion*, and if it were the first thing living, and the last that *dies*?

To which I Answer, That the *Actions* performed by *Animals*, after they are deprived of their *Heart*, are to be attributed to an *Influence* derived from thence; inasmuch as by the *Arterial Blood* convey'd to the *Brain*, the *Spirits* for a short time continue their begun *motion*, and by entering the *Nerves*, produce a *motion* in the *Tongue*, or other *Parts* of the *Body*. Thus we find that *Insects*, after they have been cut to pieces, do for a long while continue their *motion*, by reason of the strength and vigour of their *Animal Spirits*, which cannot so soon exhale out of the *Joints* of that *Expansion*, which is in them instead of a *Back-bone*, and wherein the said *Spirits* are contained. And as to that which was added, that the *Heart* is the first thing that *lives*, it is to be noted, that this is not to be understood of the time in which the *Birth* *times*, shut up in the *Mothers Womb*; but after it is come forth from the same. For it is manifest, that the *Birth* in the *Womb*, doth not so much live by a *Life* of its own, as by that of its *Mother*; and that its *Arteries* do not beat from the *motion* of its own *Heart*, but by that of its *Mother*. Wherefore tho' the *Heart* be not the *Principle* of all *motions*, that are performed in the *Body* before the *Birth*; yet is it the *Principle* of all those that are exerted afterwards.

The *Natural Heat* therefore last forsakes the *Heart*, whether in a *Natural* or *Violent Death*: For being the chief *Principle* of all *Corporal motions*, it is more strong and vigorous there, as in its *Fountain*, and makes the greatest *Resistance* against any *Force* put upon it. Thus one that hath been *Drowned*, if he be timely taken out of the *Water*, and laid with his *Head* hanging downwards, that by the voiding of the *Water* out of his *Mouth*, his *Midriff* may no longer be clogg'd by the distension of his *Stomack* from the great quantity of *Water* he hath taken down, and that by this means his *Breast* and *Wind-pipe*, being freed from that which stopp'd and oppress'd them, be restor'd to their former freedom, the *Person* returns to *life* again; because there was still some *Force* remaining in the *Heart*, whereby it was able to recommence its former *pulsation*. In like manner, a *Person* that is starved with *Cold*, being timely restor'd to warmth, Recovers again; because the *Vapours*, that were congealed in his *Breast*, begin to be dissolved and discol'd by the inward *Heat*, which was not yet wholly extinct, being assisted by the outward.

Wherefore this is the only difference that is between a *Natural* and a *Violent Death*; as by *Hanging*, *Beheading*, &c. that a *Violent Death* is performed in a moment, or a very short time: Whereas a *Natural Death* comes on by degrees, and by slow advances, dissolves the *Tye* that is between the *Parts*: But in both of them, the *Heat* and *Fire* in the *Heart* is alike extinguish'd, and takes its flight into the *Aethereal Air*, as the *Ancients* were wont to express it. Accordingly *SENECA*, in his 66th *Epistle*, saith; The *Death* of all *Persons* is alike; tho' the ways by which it makes its approaches be different, yet it ends and terminates in one and the same thing. No *Death* is more or less than other; for it hath one and the same measure and manner in all, that is, the termination or putting an end to *Life*.

VII. The Cause of this Motion.

VIII. By what means Men that have been drowned, are restored to Life.

IX. The difference between a Natural and a violent Death.

The Eighth Part OF THE INSTITUTION OF PHILOSOPHY. OF MAN, CONSIDER'D WITH Relation to his Body.

CHAP. I.

The Definition of MAN.

I.
The wonder-
ful Composi-
tion and
Structure
of Man.

WE are now come to MAN, the most Noble of all *Living Creatures*; besides whom the *Philosophers* do not esteem any thing Great that is in the *World*; as containing in himself, whatsoever is in the *Universe*; and therefore is commonly call'd, the *Compendium* or *Abridgment* of the whole *World*, and the most *Wonderful* of all *Wonderful things*, as *PLATO* styles him. It admits a Query, Whether he may not be look'd upon, as a *Prodigy* amongst all other *Living Creatures*, as consisting of such different *Parts*; and more especially for the great Disparity that is between the *Soul* and his *Body*: So that it would scarcely be a greater Wonder, if an *Angel* should be joyned to a *Beast* or *Light* make an Alliance with *Darkness*. And therefore *FICINUS*, upon *Plato Dialog. I. de Legibus* speaks thus: *And because he had said, that this one Animal was composed of such different things, he not without reason subjoyns, that Man is a Miracle or Wonder amongst all other Animals; herein imitating Mercurius Trismegistus, who calls Man, a Great Wonder, &c. But, to pass by the rest, why is Man such a Wonder? Because forasmuch as he is Divine, it is a wonder that he should be affected with Mortal things; and being Mortal, it is as great a wonder, that he should be taken with Divine things.*

Wherefore it hath always been look'd upon by *Philosophers*, to be a difficult thing to define *Man* aright, and to assign those *Terms* that might explain the Connexion of such different things, and exhibit a clear *Image* or *Idea* of him to the *Understanding*. The *PERIPATETICKS*, who conceit themselves to know the Nature of all Things, define *MAN* to be a *Rational Animal*, making *Animal* the *Genus* of *Man*, and *Rational* his *Difference*; whereby he is distinguish'd from other *Animals*. But to speak the Truth, this doth not seem to be the true *Definition* of *Man*, if we will give heed to the Rules of a *Right Definition*; the chief whereof is this, that it be *Clear* and *Evident*. Now it is manifest, that the word *Animal*, which they thrust into the *Definition* of *Man*, is obscure, and therefore cannot in the least contribute to the clear perception of him. For it is not manifest what the word *Animal* (which they make the nearest *Genus*) doth signify, without reducing it to the more remote *Genera* of a *Body*, a *Living* and an *Animated Creature*: But now, the higher we climb in the *Prædicamental Table*, the more obscure *Notions* we shall meet with; and therefore if the *Prædicats* of *Animal* be obscure, how will they be proper to explain and illustrate the Nature of *Man*?

Again, if we carefully examine what *Man*, and what an *Animal* is, we shall find, after a due balancing of the *Notion* of them both, that we do more easily understand what *Man* is, than what an *Animal* is; and that we have a more clear Conception of *Man*, than of an *Animal*. Neither

To Ralph M...
Baron of M...
in the County of
in the Parish of
of Clacton in the
County of...

can any one mend this matter, by saying that an *Animal* is, that which is *endued with Life and Sense*, since the notion of *Life and Sense* are every whit as obscure, yea more difficult to conceive. Wherefore seeing no *Definition* is to be admitted that is more obscure than the thing *defined*, and that this *Definition* of a *Reasonable Animal* doth not afford any sufficient light for the understanding of the *Nature of Man*, the same is to be rejected, and to be left in its own darkness.

IV.
Neither is
reasonable
the differ-
ence of
Man.

Besides, the word *Reasonable*, which is the other part of the *Definition*, or the *Difference*, is ambiguous; for by it must be either understood, that which is endued with *knowledge*; and then the *Difference* will agree and coincide with the *Genus*, forasmuch as according to the *PERIPATETICKS* some *Brutes*, at least, are endued with *Knowledge*, and are not meer *Engines* as we take them to be. Or else by the word *Reasonable* is to be understood *Discourse, Knowledge*, as most of them hold, and so the difference of *Man* will be taken from an inferior *Attribute*; forasmuch as *Man* the further he attains to perfection, the less he makes use of *Ratiocination* or discursive *knowledge*; and *Wise-men*, who are nearer to the nature of *Angels*, do more understand things without *Discourse*, than others do. Or lastly it imports a *simple apprehension*, whereby things are conceived, without any Relation or Reference to others, which since they allow to *Beasts* also, they will never be able to explain, what kind of *knowledge* it is they attribute to them, and how it is distinguishable from that which is peculiar to *Man*.

V.
A Rational
Animal
doth not
perfectly
explain the
Nature of
Man.

This *Definition* also is contrary to other *Laws* of a true and Rightful *Definition*, in as much as it doth not perfectly unfold the *Nature of Man*. For seeing *Man* is compounded of 2 Parts extremely different, *viz.* of a *Soul* and a *Body*, and that there is not the like conjunction of parts to be met with again in the whole *Universe* of things, it appears very plain that the *Essence of Man* cannot be exactly defined, except this most observable composition be express in his *Definition*; and forasmuch as that of a *Reasonable Animal* doth not include any such thing, it is evident that it doth but imperfectly declare the nature of the thing defin'd.

VI.
A Man is
wrongly
placed un-
der the re-
mote Ge-
nus of a
Body.

Moreover *Man* in the foresaid *Definition* is placed under the General *Head*, or notion of *Body*, when with better reason he ought to be ranked under that of *Spirit* (for the *Soul* is the *Principal* part of *Man*, and if well considered, is more known than the *Body*; for we may doubt of the *Existence of Corporeal Beings*, whereas we cannot doubt of the *Existence of our Soul*) as in all other things the denomination is always wont to be made from the more noble part; and if by evil custom, and the prejudices of our *Infancy* we have taken our *Body* to be our best and most noble Part, *Philosophy* ought to have corrected this mistake, and not to have cherish'd and strengthened it.

VII.
Why in de-
fining of
man, we
ought to
have more
regard to
his Soul
than to his
Body.

But you'll say that *Philosophers* have thought good to define *Man*, rather by his more ignoble *Genus, viz. Body*, than by that of *Spirit*, because *Man*, as to his external parts and appearance, is much more like a *Beast* than an *Angel*, and that therefore it was more proper he should be ranged under the meaner *Genus of Body*, than under that more sublime of *Angels*.

I Answer, that this is no better than a frivolous reply, as being not at all founded upon *Reason*, but *Custom* only, and the prejudices suckt in from our *Infancy*. For the *question* here is not about what objects our thoughts are most employed, but about what they ought to be employed; and that these are those things that are endued with *understanding* no *Man* will deny, these being much more excellent than *corporeal things*, and to which our *mind*, because of the affinity it hath with them, is most inclined, she herself being of an *Intelligent or Thinking Nature*. Now the reason why *Men* chiefly addict themselves to *Corporeal and sensible Things*, is because they think that their *Nature or Essence*, hath a greater affinity with *Visible Things*, than with those that never fall under their *Senses*, and can only be reached by their *thoughts*, or intellectual faculty. Which Error ought certainly to be corrected by those who may glory of their being made after the Image and likeness of God.

We must therefore look out for a more accurate *Definition of Man*, and such a one, if I be not mistaken this is: *A Man is a thing compounded of a Finite Mind, and a rightly disposed or framed Body*. For seeing that *Man* is not a simple thing, but composed of both kinds, *viz.* of a *Soul* or *Mind* and *Body*, it is necessary that this notable composition which distinguisheth *Man* from all other things, should be express in the *Definition* by this word *Compounded*; and by this means all the conditions of a good and lawful *Definition* are secured and preserved; the *First* whereof is that it express and declare the *Nature of the thing*, and the several parts whereof it is compounded. For there is nothing to be found in *Man*, which is not express in this *Definition*. Secondly, that the *Genus and Difference* be rightly assigned; for that *Man* consists of a well disposed or framed *Body*, this he hath in common with other *Animals*, and that he is endued with a *Finite Mind*, that is such an one as is not altogether perfect, he is distinguish'd from *God*, who is the *Infinite Mind*. Thirdly, that the *Definition* be not more extensive than the thing defined, nor more contracted or narrow, but equal with it; for it is manifest from *Induction* that every *Man* whatsoever is compounded of a *Finite Mind*, and a *Body* rightly disposed; so that of whatsoever the thing defined is prædicated, of the same the *Definition* may be prædicated also.

From this *Definition* we may infer *First* of all, that *Soul* and *Body* are the parts of a *Man*; as a part is taken for that, whereof any thing doth consist. Secondly, that the *Union* of the *Soul* with the *Body*, is the *Form of Man*; since wheresoever that union is, the compound is likewise, as where it is not, the compound is not, *viz. Man*. Which *Union* of the *Soul* with a *Human Body*, doth consist in the mutual *Action* of the *Soul* and *Body* upon each other, as shall be shewed in the following Part.

And whereas the other part of this *Definition* is a *Body rightly disposed*, we are to take notice that this disposition doth consist in such a *Modification*, whereby the body is fitted for an intimate union with a *Human Soul*. Wherefore every Portion of *Matter*, that is so modified, whether it be *Organical* or *Inorganical*, may properly be called a

of Man.

IX.
What may
be inferred
or gather-
ed from the
Definition.

X.
What a
rightly
disposed Bo-
dy is.

Human Body, since the *Essence* of *Man* wholly consists in the *Union* of his *Soul* with his *Body*, and that it will be his *Body* as soon as it is united to him. Neither is it any whit clear or evident, that *Organs* are of absolute necessity to this *Union*; for I can see no reason why an *Inorganical Body* may not be so disposed, as to be fit to receive a *Soul* for its *Form*. Neither can a *Man*, if we have respect to his bare *Essence* only, be said to be imperfect, because he is destitute of *Organs*, forasmuch as a *Man* that hath lost both his *Arms* and *Legs*, doth not cease to be a perfect *Man* for all that, as being no less a *Man*, than he who enjoys all his *Members*, because the perfection of a *Man* as such, consists in the union of his two *Essential Parts*, viz. of *Soul* and *Body*. And as his *Soul* is said to be perfect, because it hath that disposition which on its part is required for its union with the *Body*; so that *Body*, whatsoever it be, provided it only have such a disposition that it may be united with a *Soul*, is to be called a perfect *Human Body*. But forasmuch as we here consider *Mans Body* in its *Natural State*, we shall describe it here as it is *Organical*, and consisting of all its *Parts*.

C H A P. II.

A Description of the External Parts of Mans Body.

I.
It is sufficient for a young Scholar in Philosophy to know the more principal parts of Mans Body.

II.
How many Similar parts there be in the Body of Man.

III.
How many Dissimilar parts there be in the Body of Man.

VERY wonderful is the *Structure* of *Mans Body*, if we consider all its *Parts*, and the use or end for which they were framed: but because it would require too much time and pains, to give here a particular account of them all; and because that belongs rather to a *Physician* than a *Philosopher*, I shall only touch at the more *Principal Parts*, passing by those which would rather confound first beginners than inform them.

For the better understanding of them, we must observe that the parts which constitute the *Body* of *Man*, are either *Similar Parts*, or *Dissimilar*. *Similar* are those whose substance is the same, and alike throughout: or which may be divided into *Parts* of the same nature and Denomination; and of these I I are reckoned up by *Physicians*, viz. *Bones*, known by their great hardness and firmness; *Gristles*, which are the next in solidity and firmness to that of *Bones*, and of which the *Ear* consists. *Tendons*, which are the ends or extremities of the *Muscles*; *Ligaments*, which approach to the nature of *Tendons*, and serve to join 2 solid parts together, viz. *Bones* to *Bones*. *Fibres*, which are as it were the *Woof* of the other parts. *Membrans*, which are thin and broad substances, serving for a covering to several parts: such as are the *Membran* or *Skin* that covers the *Ribs*, the *Bladder*, the *Stomach*. *Arteries*, which convey the *Vital Blood* from the *Heart* to all the parts of the *Body*. The *Veins* which convey the *Blood* back again from the parts to the *Heart*. The *Nerves* or *Sinews* which carry the *Animal Spirits* from the *Brain* and the *Marrow* of the *Back Bone* to all parts; and the *Flesh* and the *Skin*. To which may be referred also the *Fat*, *Nails* and *Hair*, as being parts compleating the whole, and of a similar nature.

Dissimilar Parts are such as are made up of several *Similar Parts*; or which may be divided into *Dissimilar Particles*, as a *Hand*, *Foot* which

may be divided into *Skin*, *Flesh*, *Bones*, *Veins*, *Arteries* and *Nerves* which are of a different Nature and Denomination. And such are the *Head*, *Neck*, *Breast*, both the *Arms*, *Legs*, &c.

The first and Principal part of the *Human Body* is the *Head*, which contains the *Organs* of *Sense* and *Motion*, and is the *House* or *Abode* of the *Soul* it self. It is round or *Spherical*, but somewhat compressed or *flatted*, and longish: and for its better security, is all cover'd with *Bones*. And is placed in the highest part of the *Body*, according to *GALEN*, for the *Eyes* sake, which are placed there as in a *Watch Tower* to take a prospect of all objects round about it.

The *Head* is divided into the *Hairy* part or *Scalp*, and that without *Hair*, called the *Face*. The *Forepart* of the *Hairy Scalp*, from the *Forehead* to the *Sutura Coronalis*, is called *Sinciput*, that is, the *Forepart* of the *Head*; and that which reacheth from the *Sutura Lambdoidea* to the first *Joint* of the *Neck*, is called *Occiput*, or the *Hinder Part* of the *Head*; the middle and *Gibbous* part between both these, is called *Vertex* or the *Crown* of the *Head*. The part without *Hair*, that is, the *Face*, hath also its several parts, the *Forehead*, or superior part, which bears the *Signs* of the *Mind*; and the Inferiour in which are the *Organs* of the *Senses*, as the *Eyes*, *Nostrils*, *Ears* and *Mouth* which hides the *Tongue*.

There be two outward *Membrans* that encompass the *Skull*, the *Pericranium* or *Skin* so called from its going about the *Skull*, which is a soft and thin *Membran*; and the *Periostium*, which is a most thin *nervous Membran*, so closely joined to the *Pericranium*; that they seem only to constitute one *Membran*. To which are conjoined the *Inward Membrans* that infold the *Brain*, which are likewise 2, viz. a thin one, that immediately covers the *Brain*, and is called *Pia Mater*, and a thick one, which is called *Dura Mater*. They are commonly called *Meninges*, and by the *Arabian Physicians*, *Matres* or *Mothers*, because they supposed all the *Membrans* of the *Body* derived and propagated from these.

To these *Membrans* the *Vital Blood* is conveyed by the outward Branch of the *Arteries* called *Carotides*, and that which is left after the *Nourishing* of their parts, is by small *Veins* sent back to the *External Jugulars*. Some believe that these *Arteries*, passing through the little holes of the *Skull*, do penetrate and pass into the great Bosom or cavity of the *Dura Mater*: tho' this doth not seem probable, since they tend only to the *Diplois*, and in it do vanish or disappear.

The *Neck* is that part of the *Body* which is between the *Breast* and the *Face*, and supports the *Head*, being called *Collum*, & *Colendo*. Because it is commonly much adorned. It is somewhat longish, to assist the tuning of the *Voice*. Accordingly those *Animals* that utter no *Voice*, as *Fishes*, want a *Neck*; and those that have a strong *Voice*, have the longer *Necks*, as *Cranes*, *Geese*, &c. The hind part of the *Neck* is called *Cervix*; and the forepart *Guttur* or the *Throat*. The *Neck* consists of 7 *Joints*, which are the upper part of the *Spine*. In the forepart of it are 2 great *Pipes*, whereof the one is called the *Wind-Pipe* or *Rough Artery*, because of its unequal *Gristly Rings*, and serves to convey the *Air* to the *Lungs*, and from thence

out of the Body. The other inward Pipe is the Gullet; by which the Meat and Drink is conveyed from the Mouth to the Stomach.

IX. The Breast. Next to the Neck, the Breast begins, which is that part of the Body which contains the Heart, Lungs and Vital parts: Its hind-part comprehends, besides the Shoulder-blades, the Back, and 12 Joints of the Spine; from whence 7 Ribs do proceed, having their Ends clothed or cover'd with Gristles, which are called the true or perfect Ribs; because they Circle-wise compass the hollow of the Breast, reaching to the Gristle or Spongy Bone called Sternum, and ending downwards in the Gristle that resembles the figure of a Sword. In the Middle of the Breast are 2 Dugs or Paps, on each side one; situated there, First, in order to their being near the Heart, to receive heat from thence: Secondly, for Comeliness sake: Thirdly, for the more convenient Suckling of Children. They are 2 in number; not for to Suckle Twins, as some will have it, but to the end that if one of them should come to any hurt, the other might supply the place of it, and perform the Function alone.

X. The Dug is divided into the Nipple, and the Pap it self. The Nipple is a Spongy kind of flesh, and therefore is at sometimes more loose and flaggy, and at other times more stiff, especially when suck'd or touch'd. The Dug, or Pap it self, inwardly consists of a Membran, Vessels, Kernels, or rather Kernel-like Bodies, and Fat. In Men the Dugs are not so great or prominent as in Women, theirs being not commonly designed for the Generation of Milk; yet to shew the Equality of kind in both Sexes, it was not fitting that Men should be altogether without them.

XI. The Belly. Under the Breast is the Belly, whose fore-part is called Abdomen, and in its Middle is the Navil; the upper part whereof is the Hypochondrium, which Name is also given to its Sides. Beneath are the Groins, and the Parts designed for Generation. The Upper-part of the Abdomen, reaching up to the Midriff, is the Stomach, which lies Cross-ways, and which having received the Food from the Mouth, by means of the Gullet, doth digest it into Chyle; and afterwards sends the purer part of the Chyle, by the Subclavial Branches of the Vena Cava, into the Vena Cava it self.

XII. The Back-parts of the Body. The Hinder-parts of the Body are the Shoulder-blades, to which the Shoulders are joyned, and to them the Arms with the Elbow. For by the word Arm, we understand all that part which reacheth from the Shoulder, where the Collar-bones end, to the Fingers ends; tho' commonly the Hand is not comprehended under the word Arm. The Arm consists of 3 conspicuous Parts, viz. the Upper-part of it called Lacertus; the Middle-part of it, from the Elbow to the Wrist, called Cubitus, and the Hand. The Upper-part of the Arm hath one only Bone; the Middle-part hath two Bones; the Lower, which is called Ulna or Cubitus, and the Upper called Radius. The Hand also consists of 3 Parts, viz. the Wrist, the part between the Fingers and the Wrist, called Metacarpium, and the Fingers; the Fingers have each of them 3 Joints. The Hands are 2, the Right and the Left. Next to the Shoulders are the Loyns, and near to them the Os Sacrum, distinguish'd as it were into 5 Boxes, having on each side of it the

Bone Ilium, jetting out like a Bow, and the Hip-bone; and under these the Buttocks.

The use of the Flesh is, to cover the Bones and Members of the Body, more especially the Inward parts, and to hinder them from falling asunder. It is made up of the Substance of the Blood, by the coagulation of its thicker Parts. The Fat in its nature is like to Flesh, and proceeds from the same Principle. Its Function is to preserve the Natural heat, to defend the Parts it covers from Outward hurts, and by moistning and smoothing the dryer Parts of the Body, to assist and promote motion.

Flesh is fourfold; Viscerous, Membranous or Skinny, Glandulous, and Musculous, or that of the Muscles. The Viscerous is that whereof the Inwards consist, and is nothing else but an affusion of Blood, which supports the Vessels of the Inwards, by filling the empty Spaces that are between them, and assists the Concoctions and Separations that are made in them. The Membranous Flesh is nothing else, but the Flethy Substance of every Membranous part; as of the Gullet, the Stomach, the Guts, the Womb, and the Bladder. Glandulous Flesh is that of the Kernels; the use whereof is either to soak up the superfluous Humours (for they are of a Spongy Substance) as those in the Neck, under the Armpits, and in the Groin; or they are in order to the moistning of the Parts, for their more ready motion, or to prevent the dryness of the Parts. The Musculous, which GALEN calls the fibrous or stringy Flesh, is that soft and red Substance, which is Flesh, properly so called.

The Bones are the strength and support of the Flesh, and are the insensible Parts of the Organical Body of an Animal; as also the hardest and driest, containing the Marrow within them. There are 304 of them in the Body of Man, which are of diverse figures, according to their different uses; for some of them are round, others flat; some sharp, and others blunt, &c. It is a mistake to think the Bones to be without Blood; for they are Red in the Womb before the Infant is born, are found to have small Vessels in them, from whence Blood gusheth forth; and when they are broke, the Callous matter that joyns them again together, sweats Blood. The Muscles follow the bigness and figure of the Bones, to which they are joyned; and move those Members of the Body, to which they are particularly destinated. The Nerves or Sinews have fibres or strings, extended long-ways, and are the Instruments of Sense and Motion.

Lastly, This whole Bulk is supported by the Feet, assisted with the Leg and the Thigh, with the Knee that joyns them both together. The Thigh hath only one Bone in the Upper-part, whereof, besides the round Head, inserted in the hollow end of the Huckle or Hip-bone, there is a kind of Neck, whence 2 Ends shoot forth, which are called Trochanteres: And in the Lower-part this Bone is so joyned with the Chief-bone of the Shin or Leg, that in the foremost Hollow of the jetting out of the Bone, there is a place for the Bone, called the Knee-pan, which hinders the Leg from bending forwards. To the Lower-part of the Foot 3 parts concur, viz. the Heel, the Sole of the Foot, which is as it were its Back, and is made hollow in the midft,

midst, to the end it might the more firmly stick to the Ground in going ; and the 5 Toes , which are very helpful to progressive motion.

CHAP. III.

A Description of the Principal Inward Parts of the Body of Man.

I.
The Brain,
which is
the most
principal
Part of
Mans Body,
examined.

THE Skin being pluck'd off, the Flesh is more distinctly perceived; which is not a continuous *Maß*, but distinguish'd into several *Muscles*. But the chiefest and most principal Part that presents it self, is the *Brain*; which in *Man* is the greatest in Bulk, with relation to other *Animals*. The *Bark*, or outside part of it, appears distinguish'd into a thousand turnings and windings, not unlike the *Cronckelings* of the *Guts*, with far greater variety than in any other *Animal*. All which crooked Windings are covered with a thin *Membran*, and are moistened with innumerable *Vessels*; which being in a most wonderful manner woven together, are dispersed every way, and in some places penetrate the inward Substance of the *Brain*. Tho' indeed all the *Veins* and *Arteries* that penetrate the *Substance* thereof, are but small and few; but are more copious in the *Cavities* or *Ventricles* of it, and other places which are cover'd with the *Pia mater* or thin *Meninx*: For that *Membran* doth not only separate the *Brain* from the more inward Part that lies under it, but distinguisheth it also in divers parts, and invests all the deep furrows and foldings of the *Bark* or outward part of the *Brain*, conjoins the more prominent parts of them, forms almost innumerable *Cavities*, and every where twists most wonderful pleats and textures of the *Vessels*.

II.
The Brain
is divided
into two
Parts.

The *Brain* is divided into 2 parts, viz. into the *Fore* and *Hind-part*: The *Fore-part*, which is much bigger than the other, is chiefly called the *Brain*; the *Hind-part* is called *Cerebellum* or the *Little Brain*; and tends downward, being continued to the *Marrow* of the *Back-bone*, and cover'd with both the *Meninges*. Within the *Substance* of the *Fore-part* are two *Cavities*, so placed as to answer to a third Cavity in the *Hind-part*: And above the *Passage*, whereby the foresaid 2 *Cavities* have intercourse together, is the famous *Kernel* called *Glandula Pinealis*, from its figure, resembling that of a *Pine-Apple*, and *Conarion* from its *Conical* figure. The bottom of this *Gland* or *Kernel* is fastned to the *Brain*, whereof it is a part, and is seated in the very midst of the two *Cavities*. This *Kernel* hath that of Singularity, that it is one only, whereas all the other that are found in the *Brain* are double.

III.
Of the se-
ven pair
of Nerves,
derived
from the
Brain, ac-
cording to
the Opinion
of the
Ancients.

The *Ancients* were of Opinion, that 7 pair of *Nerves* only were derived from the *Brain*; whereof the first, were the *Optick Nerves*; the second, those that help to move the *Eyes*; the third and fourth, appropriated to the *Taste*; the fifth, to the *Ears*; the sixth was, that which is called the *wandering Pair*; and the seventh and last, those that move the *Tongue*. But in this enumeration, they have left out that *Pair*, which being convey'd to the *Nostrils*, are the Instruments of *Smelling*, and have divided the third *Pair* into two; and the fifth *Pair*, which they suppose single, is double: So that whereas they make but 7,

others 8, and others 9 Pair of *Nerves*, we make 10 in all. The first *Pair* are appropriated to the sense of *Smelling*, the ends whereof reaching from the *Brain* towards the *Nostrils*, are called *Processus Mammillares*. The second is the *Optick pair*, subservient to the Sense of *Seeing*. The third, moves the *Eyes*. The fourth, serves to turn and with the *Eyes* variously, suitable to the diversity of *Passions* that assail us. The fifth is, that by which the *Tongue* doth taste. The sixth is conveyed to the *Palat*, for the same purpose. The seventh is lost in the *Muscle* of the *Eye*, called the *Abductor* or *Drawer aside*. The eighth affixes the *Drum* of the *Ear*, in its dilatation or expansion. The Ninth pair, which is called *Wandering* by others, is that which furnisheth all the *Inward parts*, situate in the middle and lower *Belly*. The Tenth and last *Pair* is by strong *Membrans*, joyned with the former *Pair*, for the strengthening of them.

But forasmuch as the pith of the *Back-bone* is nothing else, but a Continuation of the Substance of the *Brain*, it is certain that from the same several pairs of *Nerves* do proceed; viz. 7 to the *Neck*, 12 to the *Back*, 5 to the *Loyns*, 6. to the *Os sacrum*; and all these *Nerves* are nothing else, but the continued Substance of both the *Meninges* or *membrans* of the *Brain*, there being none amongst them that are not twisted of them both. These *Nerves* proceeding from both sides of the Pith of the *Back-bone*, are called *Pairs*, as being always double.

In the *Breast* hangs the *Heart*, of a *Pyramidal* figure, resembling a *Pine-Apple*, with the Point of it inclining towards the Left-side; so as that the Left-part of the broad End, which is the beginning of the *Great Artery*, is situated much about the Center of the *Chest*. The Greatness of the *Heart* in *Man*, proportionably exceeds that of other *Animals*, and commonly weighs about 7 *Ounces*, being about 6 Finger-breadths long, and 4 broad. Not but that the bigness thereof sometimes varies.

In the *Heart* are 3 sorts of *Strings* or *Fibres*, some *Transverse* or *Cross-wise*, others *Crooked* or *Oblique*, and a third sort that are *Strait*, by which the dilatation or swelling of the *Heart*, when the Point of it is drawn up towards the broad End of it; and the *Contraction* whereby the said Point is withdrawn from the *basis* or broad End of it, are performed. There be 2 *Ventricles* or *Cavities* in the *Heart*, which are separated from each other by a part of the flesh of the *Heart*, called the *Septum medium*, or the middle partition Wall, the *Right Ventricle* being more ample and large than the *Left*. Two very large *Channels* answer to both these *Ventricles*, to wit, the *Vena Cava*, which is the principal *Receptacle* of the *Blood*, and is as it were the *Trunk* of the *Tree*, whereof all the other *Veins* are the *boughs* and *branches*; and the *Arterial Vein*, which ariseth from the *Heart*, and after that it is come forth from thence, divides it self into many *branches*, which are afterwards dispersed through the *Lungs*. In the Left-side there are likewise 2 corresponding *Channels*, as large as the former, if not larger, viz. the *Venal Artery*, which is derived from the *Lungs*, where it is divided into many *branches*, which are intermixed with the *branches* of the *Arterial Vein* and the

traction
of the
Heart.

Wind-

Wind-pipe, by which the Air we attract doth enter; and the Great Artery, which proceeding from the Heart, disperseth its branches throughout the whole Body. Each of these Cavities have 2 Openings, placed towards the basis or broad End of the Heart: And in the entrance of these Openings, are some little Skins, which like so many flood-gates do open and shut 4 Mouths or Orifices, that are in both those Cavities; viz. 3 in the entry of the Vena Cava or hollow Vein, which are so placed, that they cannot hinder the Blood they contain, from flowing into the Right Ventricle of the Heart, tho' they hinder any from coming out thence. 3 in the Entry of the Arterial Vein, which are ranged the quite contrary way, so as that they suffer the Blood, contained in that Cavity, to pass to the Lungs; but by no means will suffer that which is in the Lungs, to return thither again. And so likewise there are 2 more in the Orifice of the Venal Artery, which permit the Blood to pass from the Lungs into the Left Ventricle of the Heart, but hinder its return thither again. And 3 at the entry of the Great Artery, which suffer the Blood to come from the Heart, but hinder it from returning thither again.

VII. The Heart is enclosed in a Nervous membran, called Pericardium; where it swims in a Liquor not much unlike to that of Urin; the broad End of it taking up the Center of the Breast, whilst the Point of it sways downwards, to the Left-side of the Midriff.

VIII. The Lungs are a Spongy substance, of a whitish or pale red Colour, and are divided in the Right and Left part by the Mediastinum, or the membran that divides the Breast, from the Throat to the Midriff, into 2 Bosoms; both which Parts are distinguish'd into several Lobes or Lappets, in order to their better covering and surrounding of the Heart, which is placed in the midst of them. In that part of the Mouth which is at the Root of the Tongue, is a Channel called the Wind-pipe, which passing downwards is divided into many little branches, which are dispers'd throughout the whole Substance of the Lungs, in the same manner as the Venal Artery, or the Arterial Vein. This Wind-pipe receives the Air that is taken in by breathing; and because the membran thereof is so hard and stiff, that it cannot easily be compress'd or clos'd together, it continues always full of Air, and by this means causeth the great Lightness of the Lungs. Our Meat and Drink cannot pass from our mouth into the Gullet, without passing over the Mouth of the Wind-pipe, tho' nothing can fall into it, because of a little Valve which covers it, whenever we swallow any thing. The Lungs also have their Dilatation and Contraction; their Dilatation being caused by the Air entering into their Substance through the Wind-pipe; and the Contraction by the expulsion of it.

IX. Under the Lungs and the Heart is placed the thick membran, called the Diaphragm or Midriff, which separates the Breast from the Belly. It hath 2 Holes, through which the ascending Hollow Vein, and the Gullet which goes down to the Stomach, do pass. The Midriff lends also its assistance to the function of Respiration, to which it contributes rather, as it is a Muscous membran, than a Muscle.

X. Under the Diaphragm, the Liver is placed on the Right-side, and the Spleen on the Left. The

Liver in Man, as well as in most other Animals, seems to be nothing else but Clotted blood, of a Reddish colour. Tho' there be some Animals that have it of a green, others of a yellow, and others of other Colours. The Ancients were of Opinion, that the Blood was prepared in the Liver, and that the Chyle was there turned into the form of Blood. But the contrary has been since made out, it being no longer question'd now, but that the Chyle is conveyed from the Receptacle of the Lacteal Veins upwards, to the Subclavial branches of the Hollow Vein, and thence into the ascending Trunk of the said Hollow Vein, whence it is carried together with the Blood, returning from all the parts of the Body, into the Right Ventricle of the Heart, without passing the Liver. The Gall-bladder is joyned to the Liver, a small Channel proceeding from it, which becomes immediately parted into 2, whereof the one bends downwards towards the Liver again, and enters it; whereas the other, called Choledochus, is inserted into the lower end of the Duodenum, whither the Gall is conveyed, through a very little and almost insensible Orifice.

The Spleen is situated on the Left-side, under the Midriff, between the Stomach and the Ribs. It is of a Spongy substance, cover'd with a thin membran, received from the Peritonaeum or Inner-rim of the Belly. Its more prominent or gibbous part is fastned to the Midriff; which is the Reason why those that are diseased with a Schirrus, or any other swelling of the Liver, do complain of a difficulty of breathing. It abounds with a thick dreggy Blood, and is fastned to the Stomach and Back, by means of the foresaid membran, and hath a communication with the Heart by certain Arteries and Veins. The Spleen is almost as long again as it is broad; the Upper-part of it butting out like a Bow, the Lower-part of it ending in an obtuse Angle, and in the midst somewhat hollow and deprest.

Between the Liver and the Spleen lies the Stomach, into which all our Meat and Drink is conveyed through the Gullet. It hath 2 Orifices, the one whereby it receives in our Nourishment, which it dissolves and turns into Chyle; the other called Pylorus, by which it thrusts it down into the Guts.

For the Guts take their rise or beginning from the neather Orifice of the Stomach, and after many windings are terminated in that part, by which the grosser Excrements are voided. To speak properly there be no more than one Gut, to the different parts whereof Anatomists have assigned different Names. That which is next to the Stomach they call Duodenum, the extent of which is not above 12 fingers breadth: The second is called Jejunum, from its almost continual emptiness: The third is called Ilium, from its various windings: The fourth, Colon, whence the Disease called the Colick takes its Name: The fifth is a little Appendix betwixt the Ilium and Colon, which is called Caecum, or the Blind-Gut: And the sixth Rectum, or the Strait-Gut. The 3 former of these are called the thin Guts, and the rest the great or thick Guts.

The Mesentery is a Membranous expansion, interwoven with Kernels and Fat, placed at the back-part of the Guts, and with its Center or narrowest part tied to the Loins; but with its Circumference

The Mesentery.

cumference infolding all the *Guts*, and fastning them to the *Back*. Its figure is almost Circular, so as that its compass answers to the length of the *Guts*; but yet is so framed and folded, that it keeps within narrow Bounds.

XV. *The Caul.* The *Caul* is another *Membranous* expansion, consisting of a double *membran*, distended to an Orbicular figure, like to a *Faulkners Pouch*, interwoven with many *Arteries* and *Veins*, and great store of *Fat*, deriving its 2 *wings* or foldings from the *Stomach*, *Liver*, *Spleen*, the *Rim of the Belly*, and the *Gut Colon*; and not only covering the *Guts*, but following the windings and turnings of them; so that with regard to its situation it may well be called *Epiploon*, that is, swimming on the top, such being the situation of it with respect to the *Guts*.

XVI. *The Womb.* The *Womb*, which is also called the *Matrix*, is an *Organical* part, serving for *Generation*, situate in the lower part of the *Belly*, betwixt the *Bladder* and the *Strait-Gut*, lodged in a strong *Bason*, made by the *Bones Ilium*, *Coxendix*, and *Sacrum*; which *Bason* or *Hollow* is larger in *Women*, than in *Men*, in whom also when the time of their *Delivery* is at hand, it is yet further enlarged by the plying and giving-way of some of the strong *Ligaments* about the *Bones Sacrum* and *Pubis*, and by the starting back of the *Bone* called *Coccyx*, to make way for the *Birth* to struggle out of his *Prison*.

XVII. *The Kidneys.* Besides these *Parts* already mentioned, there are also 2 *Kidneys* that are fastned to the *Joints* of the *Back-bone*. Their Substance appears like to that of a curious *Sponge*, and in each of them is found a certain *Cavity* or *Hollow*, called the *Dish* or *Bason*, which is generally fill'd with *Urin*.

XVIII. *The Ureters.* The *Ureters* are 2, viz. on each side one, carrying the *Urin*, that hath been separated in the *Kidneys* to the *Bladder*. They are nothing else, but an innumerable company of small *Nervous fibres* twisted together, and therefore no wonder that they are so exceeding sensible; for as soon as any one of their finest *Strings* is moved, all the rest are shaken and tremble, whence there ariseth in the *Soul* an *Idea* of the sharpest *Pain*.

XIX. *The Bladder.* *Anatomists* commonly attribute but 2 *Coats* or *membrans* to the *Bladder*; but if they be viewed with a *Microscope*, we shall find them to be many more, even to the number of 20. The *Bladder* is the receptacle of the *Urin*, conveyed through the *Ureters* from the *Kidneys*; which afterwards by the contraction of the fibres of the *Bladder*, are by the *Urethra* or *Urinary passage* evacuated.

XX. *The Testicles.* The last *Parts* to be consider'd, are the *Testicles*, which are *Vessels* design'd for *Generation*, tho' it may be doubted, whether the *Generation* of *Seed* may be wholly attributed to them; because there was never found any perfect *Seed* in the *Testicles* of the most *Libidinous Animals*. Yea, many do witness, that *Bulls*, *Horses*, and other such like *Robust Animals*, have generated their *Like* for many years together, after their having been *geld*, and that they are not robb'd of their *Prolifick* virtue, except their *Spermatick Vessels* be taken away together with their *Testicles*. Wherefore it seems more probable, that the *Seed* is produced in the little *Bladders*, *Kernels*, and *Pores*, that neighbour upon the *Bladder* and the *Womb*. But we leave this to be determin'd by *Physicians*.

C H A P. IV.

Of the Forming of the Birth in the Womb, and of its Animation.

THE Common Opinion is, that the Matter whereof the *Birth* is formed in the *Womb*, doth consist of the *Seed* of both *Parents*, the *Female Blood* being mix'd with it: Nor indeed have the *Ancients* question'd, but that the *Woman* doth contribute her part of *Seed* to the *Conception*, and efficiently concur to *Generation*; for both *Sexes* seem to have like *Instruments* for the generating of *Seed*. The *Women* have their *Testes*, in which the *Blood* is strained and purified, and a serous and thickish white Matter is squeezed out of them, which seems to be design'd for *generation*. Besides, we find that the *Birth* resembles the *Mother*, as well as the *Father*; which we cannot well conceive how it should be, if both of them did not contribute *Seed* to the production thereof.

But to the end we may understand by what Artifice an *Animal* comes to be formed, from a Moisture without all Form, so as to bear some resemblance with the *Principle* from whence it did proceed; it is commonly supposed, that the *Seed* both of *Male* and *Female* flows down from all their *Parts*, so as that there is no *Member* in their whole *Bodies*, whence some part of the *Seed* is not derived. For as the *Serous humour* is by the *Veins* separated from the whole *Body*, and through the *Vessels* call'd *Emulgentes* carried to the *Kidneys* and *Bladder*, in which latter place it is kept till it be voided: In like manner, say they, seeing that 2 *Veins* and 2 *Arteries* enter into the *Testicles*, why may not the *Seminal particles* flow from the whole *Body* into them, and from them into the *Vessels* destined for their reception; and this not slowly and by degrees, but in a very short Space, wherein the whole *Body* is powerfully stirr'd up to an excretion or separation of what is most *Spiritous* in all the *Parts* of the *Body*?

Many Arguments might be alledg'd to prove this Point; but there are some Examples thought to be so clear and evident, as to supersede the necessity of many Proofs: A *Cat*, whose *Tail* was cut off when she was but young, litter'd *Kittlings*, whereof some had *Tails*, and others wanted them: And a *Bitch*, that was wont to bring forth sound *Puppies*, having broke her *Leg*, did ever after bring forth lame *Puppies*. Now to what can this resemblance of *Puppies*, with their *Dams*, be imputed, but because the *Seed* is conveyed from all the parts of the *Body*, so that perfect *Births* are born of sound and perfect *Parents*, and maimed and defective from such as are so. And if it sometimes happens, that whole and sound *Births* do proceed from maimed and defective *Parents*, this must be ascribed either to the Soundness of one of the *Parents*, or to the great Vigour of the *Spirits*. However, when it so happens that maimed *Births* proceed from maimed *Parents*, no other Reason seems so satisfactory, as that which hath been alledged.

From what hath been said, may in some sort be understood, how the *Birth* comes to be formed in the *Mothers Womb*; because the insensible *Parts* of the *Male* and *Female Seed* have already received such a Configuration in the *Body* of the *Parents*, that they are no sooner received into the *Womb*; but

I. Whether the Seed in Generation, proceeds from both Sexes.

II. The Seed flows from all parts of the Body.

III. Proved by Examples.

IV. How the Birth is formed in the Womb.

but being there intangled together, and agitated by heat, they are turned into a rude delineation or Rudiment of the Animal, from which afterwards all the parts are perfected and compleated. For those parts which before, for example, did belong to the Head, Belly, &c. become now so disentangled and separated from others, so as to be now at liberty to run together, and from the several distinct parts of the Body; so that those parts which proceeded from the Brain, do now unite to constitute that part, those of the Eyes, the Eyes and so for the rest. Much after the same manner as the like grains of Sand, and the filings of Lead do come together, and make several heaps: as when we fasten a Pipe to a Bladder, and through it cast Earth, Sand and Filings of Lead, and having poured water upon them, if then we blow through the Pipe, all these matters will be variously mingled and tost together, but as soon as the said agitation ceaseth a separation is made, the Lead settling with the Lead, the Sand with the Sand, &c. and in this condition we shall find them, if after the drying up of the water we shall rend the Bladder, that is, we shall find the like particles to be gathered to their like. And after this manner we may conceive that the particles of the Seed become so disposed as to make the first Rudiment of a Birth.

V. How the first Rudiment of the Birth comes to be like Man.
If you demand how it can be that from such a small quantity of Insensible particles, a Body should arise, resembling the great Body from whence it proceeded, and representing every one of its Parts and Members.

It is Answered, that this is done much in the same manner as we find that a very little Image in a Convex Glass represents a Man; for this Image is therefore so little, because only a few rays are reflected to the Eye, from the several parts, many of the Rays rebounding elsewhere by reason of the convexity of the Glass, which makes that only a few Beams from each part do reach the Eye, which meeting in the Retina or Network Membran of the Eye, do represent a very little Man: In like manner, the first Rudiment of a Human Birth in the Womb, is indeed very little, and yet resembles the great Body, exactly as to the number of its parts, tho' not as to the quantity and bulk of them.

VI. The Time of the Formation of the Birth.
Physicians are at some disagreement about the time of the formation of the Birth. HIPPOCRATES Lib. 1. de Carn. tells us that the Seed being received into the Womb, by the seventh day hath whatsoever it ought to have, and that if an Abortive at the end of this term, be put into the water, and accurately viewed, the rude draught of all the parts will be discernible in it. Others allow a longer time for this forming of all the Parts: ARISTOTLE Lib. 7. Hist. Animal. saith that the Body of the Birth on the fortieth day, consists, as it were, in a Membran, which being rent, the Birth appears of the bigness of a great Pismire, in which all the Members may be distinctly seen.

VII. What the Architectonic or Plastick virtue is.
Now what this Plastick or formative virtue is that lies hid in the Seed, which begins and carries on the formation of the parts, all are not agreed. GALEN sometimes calls it Nature, sometimes Native Heat, sometimes the Inborn Temperature, and sometimes Spirit, which in his Book de Trem. & Vigor. he determines to be a substance

moveable of it self, and always moving. ARISTOTLE, Lib. 2. de Generat. Animal. Cap. 3. distinguishing betwixt the Heat or Spirit of the Seed, and Nature, saith that the Plastick Virtue, is the Nature that is in the Spirit of the Seed. AVICENNA and others following AVERROES call it a Caelestial Power, or Divine Virtue. Some admit no other Soul in Man but the Rational, and maintain that it alone, out of convenient seminal matter offered to her, doth perfect all the Lineaments of the parts, and that she is the Architect of her own House. Others affirm that there is a Vegetative or Vital Soul in Man, which is Mortal and distinct from the Rational, and that this Soul is the chief, yea sole Operator in the forming of the Birth, and the very same which some call the Plastick or Architectonic Virtue.

The Antients differ also, as to what parts of the Body are first formed. ARISTOTLE was of opinion that the Heart was first formed, as being the Fountain of Heat, and the Principle of the Animal Life. For it seems very consonant to Reason, that what dies last, should have the precedence in formation. Others suppose that all the parts of the Birth are formed at once, and contend that there is no reason why the Heart should have any such Praeeminence allow'd it. For why, say they, should the Heart be formed before the other parts, seeing that in the framing of the Members, the Birth doth no more stand in need of the Influence of the Heart than of the Sense of the Brain? Nature digests the whole Mass of the Seed with one and the same Heat, which equally penetrates all the parts of it; so that when she begins to frame a Body, she doth not confound the particles of the Seed, but distributes them all into their several places. Which distribution of the Seed cannot consist with a successive Generation of Parts; seeing it is equally requisite, that a part fit to form the Brain should be taken from the Heart, as it is that the Brain should communicate a part proper to constitute the Heart: Besides, Nature might be accused of Impotence, if she could not perfect and compleat those things together at once, which she hath begun at once.

Neither is it contradictory to this assertion, that some parts appear to us before others, because this is only to be attributed to their greater bulk. For the greater parts seem by Nature to be before the less; but we cannot therefore infer from hence that they exist before them; because all the Members of the Body are not perfected and compleated at the same time, but according as they are more or less nourished or heated. Wherefore HIPPOCRATES Lib. 1. de Dieta saith that all the Members are distinguished and encrease together; not one before or after the other; tho' those parts which be greater by Nature than others, do appear before the lesser, but do not exist before them. For the order of Nature is, that the more worthy parts, and those that are designed for the use of others, should appear first, and therefore it is that the upper parts appear before the lower, and those which are formed of the Seed, before those that are formed of the Blood. But yet it sometimes happens, that the more imperfect parts are framed before others, as is manifest in the Navel, which is perfected before either the Heart or Brain.

This

VIII. What Parts of the Body are first formed.

IX. All Parts of the Birth are formed together, notwithstanding that some parts be seen before others.

X.
This fur-
ther proved
from a
Chicken.

This may be proved by Experience; because never was there any Birth found, in which the Heart or any other part was formed, before the other parts were framed also. For tho' in the forming of a Chicken, about the fourth day, the Head and Body of the Chicken begin to appear, when neither Wings or Legs are yet distinguishable, yet even at that time the Rudiments of those parts are there, tho' so little as not discernible by the bare Eye. And thus much concerning the opinion of the Antients about the forming of the Fetus.

XI.
Dr. Har-
vey's opini-
on concern-
ing Con-
ception.

Dr. HARVEY was the first of Modern Authors who maintained, that the Masculine Seed did not concur to the constitution of the Birth; because in the many Animals he dissected after Copulation, he never found any Seed in their Wombs, and therefore was induced to believe, that the Seed of the Male did never reach the hollow of the Womb, or if it did, that it never staid there, but soon after slipt away: and accordingly he supposed that the Male-seed, only by a prolifick breath or contagion, doth make the Female conceive. Secondly, That the Natural Conception in the Womb, happens much in the same manner, as doth the Animal Conception in the Brain: for as we, after having framed an Idea in our Brain, do express the likeness of it in our Works; so likewise the Idea or Species of the Begetter, tho' the Geniture or Seed be absent, by the help of the Formative Faculty, doth beget a like Birth, by impressing the Immaterial Species it hath upon its work.

XII.
How Con-
ception is
performed
according
to Steno,
and other
later Phy-
sicians and
Anatomists.

In the year 1670, STENO a famous Anatomist, discovered that the Female Testicles so called, are nothing else but Ovaria, that is, Receptacles of Eggs, which hath been since confirmed by the Writings of KERCKRINGIUS, SWAMMERDAM, GRAAF, GASPAR BARTHOLINUS and others. And accordingly the received opinion now is, that the Birth, with all its parts, lies hid in these Ovaria, tho' not to sensible appearance. And therefore maintain that the Birth is not formed of the Seed, but that the most Subtil Spirit only of the Masculine Seed is conveyed through the bottom of the Womb and the Tubes or Trumpets (so called by FALLOPIUS for their resemblance with that Instrument) to the Female Ovarium, where it impregnates one of those little Eggs, that is, causeth or excites a Fermentation in it, which makes the Egg to swell, and to require a greater space, by which means it cracks the common Membran of the Ovarium, and through the slit of it, is driven into the Fallopian Tubes by those shaggy edgings which are at the end of the said Tubes, and by Anatomists are called the Leaf-work Ornament, being blown up and distended by the Animal Spirits, and which at the time of Copulation, like so many Fingers, clasp themselves about the Ovarium; and thus the Egg is conveyed through the whole length of the Fallopian Tubes to the bottom of the Womb, where it is further hatched into a Living Birth.

XIII.
The Point
illustrated
from a si-
militude
betwixt the
Vegetation
of Plants
and Ani-
mals.

The Learned Mr. RAT illustrates this matter in his History of Plants from the Analogy and similitude there is between the Vegetation and encrease of the Seeds of Plants in the Earth, and of Viviparous Animals in the Womb. For even as, saith he, the ripe Seed of a Plant falls down to the Earth, and being there free and at liberty, doth first of all attract the Aliment through the pores

of its coverings, and afterwards shoots down roots into the Earth; so likewise the Egg of a Viviparous Animal, being by the Masculine Seed made Fruitful, and brought to Maturity, falls down from the Ovarium as from its Tree, into the Womb, as the Earth, where continuing for some time loose and at liberty, without being fastned to the Womb, it takes in its first Aliment through the involving Membrans or Secundines. These Ovaria are nothing else but the Female Testicles formerly so called, which he that diligently views will find them to be nothing else but a Cluster of little Eggs.

Admitting this opinion, we may easily resolve the following Difficulties, according to SWAMMERDAM in his Miracle of Nature, or the Structure of a Womans Womb. First, Why a Parent that wants Arms or Legs may notwithstanding propagate a Birth, perfect and compleat in all its parts; even because all the Parts of it are contained in the Egg. Secondly, So likewise that old and famous Question, whether the flowing of the Seed from all the parts of the Body be required to the perfection of the Birth, is readily answered. Thirdly, Hence it appears how Levi, long before his Birth, was said to pay Tenth, in, or with his Great Grand-father Abraham to Melchizedeck, to wit, because he was in the Loins of his Parents, as all the parts of an Animal are in the Egg. And Fourthly, Hence also may be explained and illustrated the ground and foundation of Original Corruption, because all Men that ever were, or shall be, were hid in the Loins of Adam and Eve, to whom therefore it may be easily conceiv'd, that that primordial Taint must have been necessarily propagated from these their First Parents.

Now as to the time of the Animation of the Birth, Authors are likewise at great variance. ARISTOTLE supposeth that a Male Body receives its Soul the 42d day after Conception, and a Female on the 19th. Whereas AENEAS GAZAEUS will have the Soul not to be put into the Body already formed, but into the Seed it self, whilst it is yet without Form. THOMAS FIENUS, in his Book de Format. Fetus, determines the Infusion of the Soul to be the third day. But if it be lawful to guess at a thing so obscure as this is, it seems most probable that the Soul is then joined to the Body, when it is furnished with all its Organs, that is, after the formation of the Belly, Heart, Brain, the Pineal Kernel, and all the other Parts, which Anatomists tell us happens about the Fourth Month.

CHAP. V.

How the Body of Man is nourished and encreased.

FORasmuch as those parts that are so turned into our Substances, as to preserve our Body in the same state and condition only, are said to nourish us; and that those parts, which being transmuted into our Bodies, do make it greater in Bulk than it was before, are said to encrease it, and make it grow, we may easily apprehend what Nourishment and Growth is.

The

XIV.
Many diffi-
culties may
be solved
from this
Hypothesis.

XV.
At what
time the
Soul is in-
fused into
the Body.

II. The manner how both these are performed will more plainly appear, by taking an exact view of the changes of those *Aliments*, whence the Principles of our *Blood* are derived. First, It is evident that, besides the *Culinary Preparation* of the *Aliment*, it is chewed by the *Teeth*, and being mingled with the *Spittle* is sent down into the *Stomach*.

2ly. That in the *Stomach* it undergoes a special *Fermentation*, whereby it is yet further dissolved. 3ly. That from this dissolved and digested *Mass*, by another peculiar effervescence or working in the *Guts*, are separated the more useful and pure parts of the *Chyle*, from those that are more thick and gross, which are yet farther dissolved and attenuated in the *Lacteal Veins*, and the *Kernels* of the *Mesentery*, as also by the Commixture of the *Lymphatick Juice*; and at last being mingled with the *Blood* in the *Veins*, are carried to the *Heart*; where having past another effervescence, they become united with the rest of the *Blood*, there being now no more any difference between them.
